Updating LUNs	21
Modifying an NFS file share by using APIs to support CIFS	24

API workflows for workload management

Using Active IQ Unified Manager, you can provision and modify storage workloads (LUNs, NFS file shares, and CIFS shares). Provisioning consists of multiple steps, from the creation of the Storage Virtual Machine (SVM) to applying Performance Service Level and Storage Efficiency Policies on the storage workloads. Modifying workloads consist of the steps for modifying specific parameters and enabling additional features on them.

The following workflows are described:

- Workflow for provisioning Storage Virtual Machines (SVMs) on Unified Manager.

this workflow is required to be performed before provisioning LUNs or file shares on Unified Manager.

- Provisioning file shares.
- Provisioning LUNs.
- Modifying LUNs and file shares (by using the example for updating the Performance Service Level parameter for the storage workloads).
- Modifying an NFS file share to support CIFS protocol
- Modifying workloads to upgrade QoS to AQoS

For each provisioning workflow (LUN and file shares), ensure you must have completed the workflow for verifying the SVMs on the clusters.

You must also read the recommendations and limitations before using each API in the workflows. The relevant details of the APIs are available in their individual sections listed in the related concepts and references.

Verifying SVMs on clusters by using APIs

Before provisioning file shares or LUNs, you must verify whether the clusters have Storage Virtual Machines (SVMs) created on them.

The workflow assumes that ONTAP clusters to have been added to Unified Manager, and the cluster key has been obtained. Clusters should have the required licenses for provisioning LUNs and file shares on them.

1. Verify whether the cluster has an SVM created.

Category	HTTP verb	Path
datacenter	GET	/datacenter/svm/svms /datacenter/svm/svms/{key}

Sample cURL

```
curl -X GET "https://<hostname>/api/datacenter/svm/svms" -H "accept: application/json" -H "Authorization: Basic <Base64EncodedCredentials>"
```

2. If the SVM key is not returned, then create the SVM. For creating the SVMs, you require the cluster key on which you provision the SVM. You also need to specify the SVM name. Follow these steps.

Category	HTTP verb	Path
datacenter	GET	/datacenter/cluster/clusters /datacenter/cluster/clusters/{key}

Get the cluster key.

Sample cURL

```
curl -X GET "https://<hostname>/api/datacenter/cluster/clusters" -H "accept: application/json" -H "Authorization: Basic <Base64EncodedCredentials>"
```

3. From the output, get the cluster key, and then use it as an input for creating the SVM.

While creating the SVM, ensure that it supports all the protocols required for provisioning LUNs and file shares on them, for example, CIFS, NFS, FCP, and iSCSI. The provisioning workflows might fail if the SVM does not support the required services. It is recommended that the services for the respective types of workloads are also enabled on the SVM.

Category	HTTP verb	Path
datacenter	POST	/datacenter/svm/svms

Sample cURL

Enter the SVM object details as input parameters.

```

curl -X POST "https://<hostname>/api/datacenter/svm/svms" -H "accept: application/json" -H "Content-Type: application/json" -H "Authorization: Basic <Base64EncodedCredentials>" "{ \"aggregates\": [ { \"_links\": {} , \"key\": \"1cd8a442-86d1,type=objecttype,uuid=1cd8a442-86d1-11e0-ae1c-9876567890123\" , \"name\": \"cluster2\" , \"uuid\": \"02c9e252-41be-11e9-81d5-00a0986138f7\" } ] , \"cifs\": { \"ad_domain\": { \"fqdn\": \"string\" , \"password\": \"string\" , \"user\": \"string\" } , \"enabled\": true , \"name\": \"CIFS1\" } , \"cluster\": { \"key\": \"1cd8a442-86d1-11e0-ae1c-123478563412,type=object type,uuid=1cd8a442-86d1-11e0-ae1c-9876567890123\" } , \"dns\": { \"domains\": [ \"example.com\" , \"example2.example3.com\" ] , \"servers\": [ \"10.224.65.20\" , \"2001:db08:a0b:12f0::1\" ] } , \"fcp\": { \"enabled\": true } , \"ip_interface\": [ { \"enabled\": true , \"ip\": { \"address\": \"10.10.10.7\" , \"netmask\": \"24\" } , \"location\": { \"home_node\": { \"name\": \"node1\" } } , \"name\": \"dataLif1\" } ] , \"ipspace\": { \"name\": \"exchange\" } , \"iscsi\": { \"enabled\": true } , \"language\": \"c.utf_8\" , \"ldap\": { \"ad_domain\": \"string\" , \"base_dn\": \"string\" , \"bind_dn\": \"string\" } , \"enabled\": true , \"servers\": [ \"string\" ] } , \"name\": \"svm1\" , \"nfs\": { \"enabled\": true } , \"nis\": { \"domain\": \"string\" , \"enabled\": true } , \"servers\": [ \"string\" ] } , \"nvme\": { \"enabled\": true } , \"routes\": [ { \"destination\": { \"address\": \"10.10.10.7\" , \"netmask\": \"24\" } , \"gateway\": \"string\" } ] , \"snapshot_policy\": { \"name\": \"default\" } , \"state\": \"running\" , \"subtype\": \"default\" } "

```

The JSON output displays a Job object key that you can use to verify the SVM that you created.

4. Verify the SVM creation by using the job object key for query. If the SVM is created successfully, the SVM key is returned in the response.

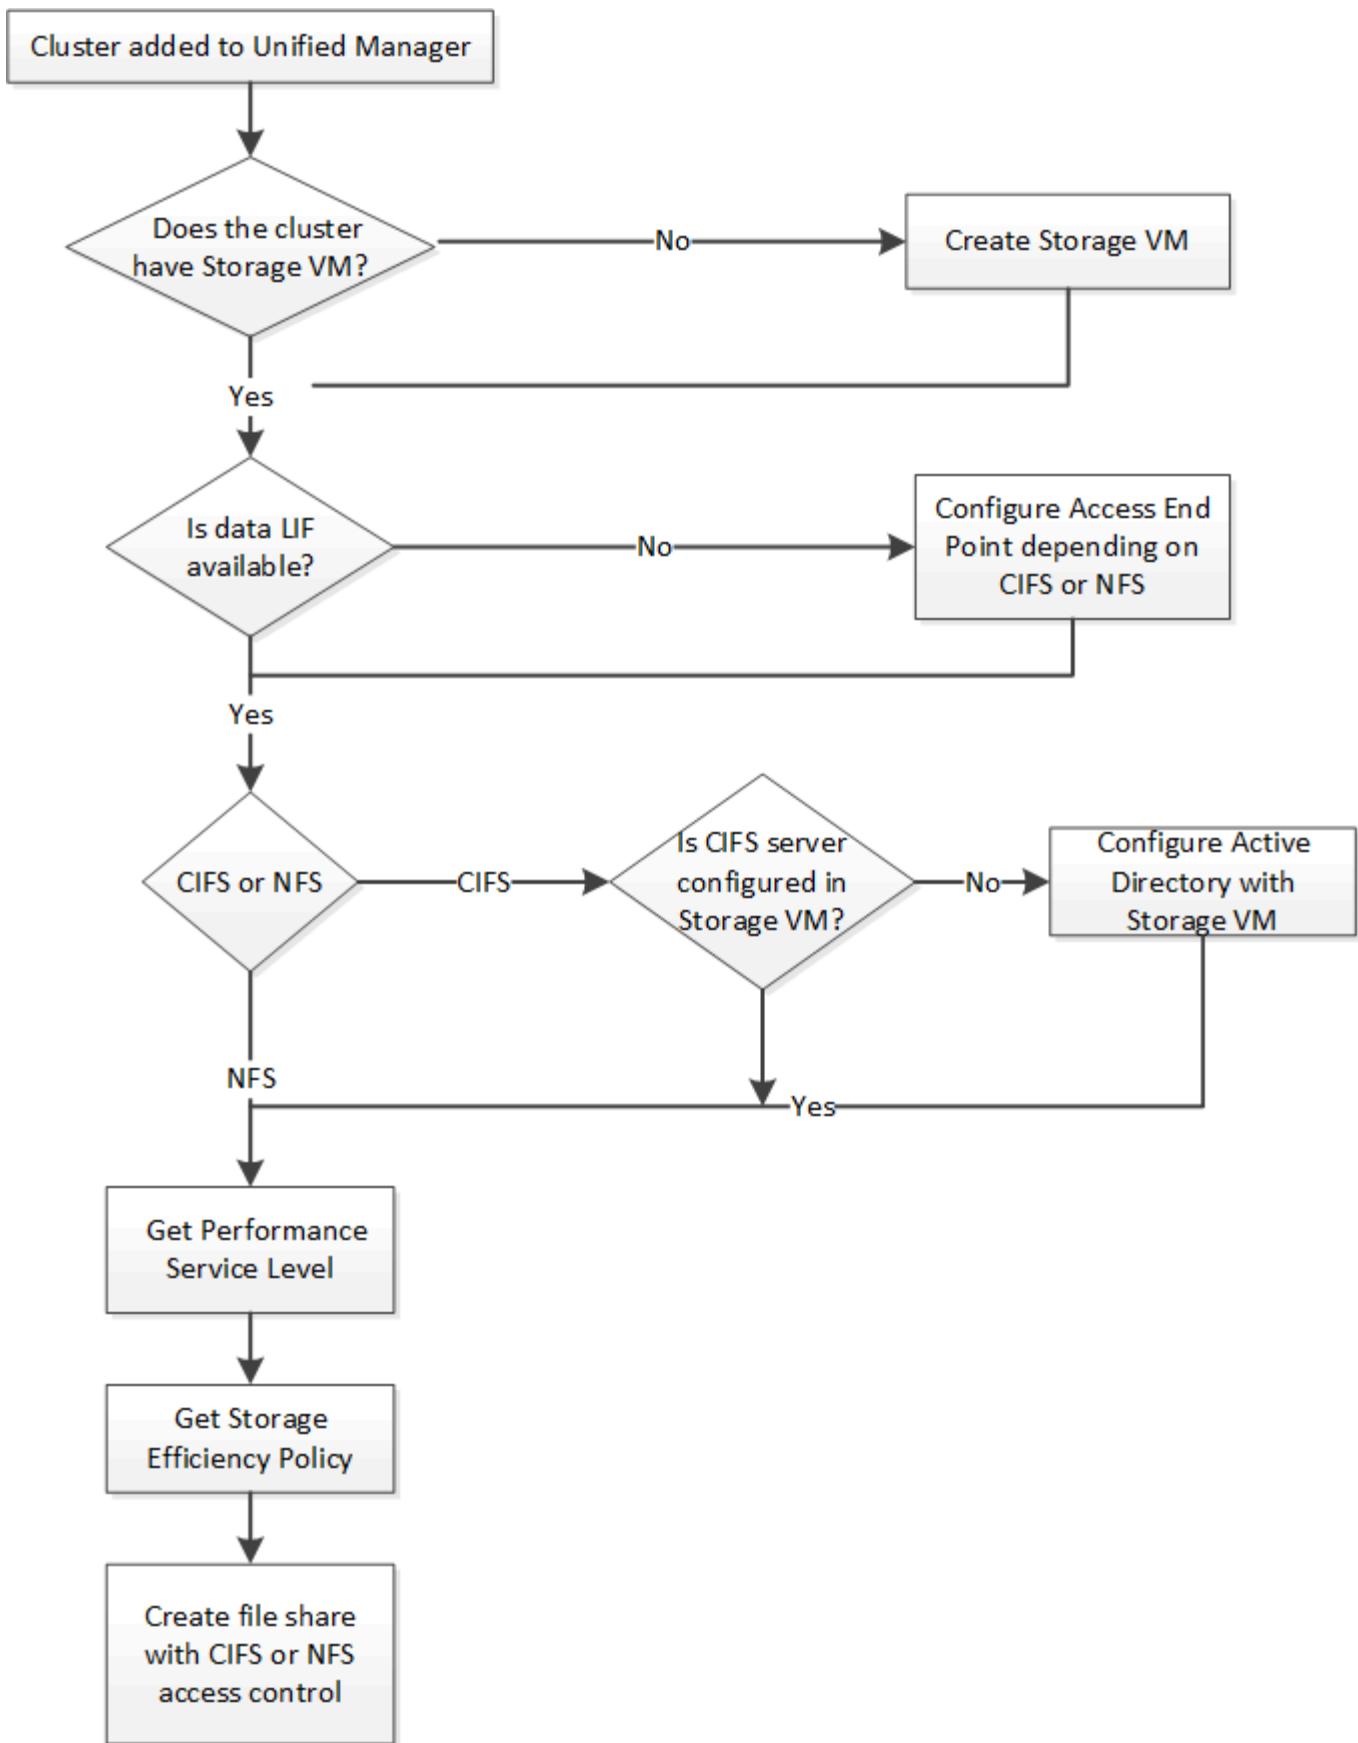

Category	HTTP verb	Path
management-server	GET	/management-server/jobs/{key}

Provisioning CIFS and NFS file shares by using APIs

You can provision CIFS shares and NFS file shares on your Storage Virtual Machines (SVMs) by using the provisioning APIs provided as a part of Active IQ Unified Manager.

This provisioning workflow details the steps for retrieving the keys of the SVMs, Performance Service Levels, and Storage Efficiency Policies before creating the file shares.

The following diagram illustrates each step in a file share provisioning workflow. It includes provisioning both CIFS shares and NFS file shares.

Ensure the following:

- ONTAP clusters have been added to Unified Manager, and the cluster key has been obtained.
- SVMs have been created on the clusters.
- The SVMs support CIFS and NFS services. Provisioning file shares might fail if the SVMs do not support the required services.
- The FCP port is online for port provisioning.

1. Determine whether Data LIFs or access endpoints are available on the SVM on which you want to create the CIFS share. Get the list of available access endpoints on the SVM:

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/access-endpoints /storage-provider/access-endpoints/{key}

Sample cURL

```
curl -X GET "https://<hostname>/api/storage-provider/access-endpoints?resource.key=7d5a59b3-953a-11e8-8857-00a098dcc959" -H "accept: application/json" -H "Authorization: Basic <Base64EncodedCredentials>"
```

2. If your access endpoint is available on the list, obtain the access endpoint key, else create the access endpoint.

Ensure that you create access endpoints that have the CIFS protocol enabled on them. Provisioning CIFS shares fails unless you have created an access endpoint with the CIFS protocol enabled on it.

Category	HTTP verb	Path
storage-provider	POST	/storage-provider/access-endpoints

Sample cURL

You must enter the details of the access endpoint that you want to create, as input parameters.

```

curl -X POST "https://<hostname>/api/storage-provider/access-endpoints"
-H "accept: application/json" -H "Content-Type: application/json" -H
"Authorization: Basic <Base64EncodedCredentials>"
{ \"data_protocols\": \"nfs\",
\"fileshare\": { \"key\": \"cbd1757b-0580-11e8-bd9d-
00a098d39e12:type=volume,uuid=f3063d27-2c71-44e5-9a69-a3927c19c8fc\" },
\"gateway\": \"10.132.72.12\",
\"ip\": { \"address\": \"10.162.83.26\",
\"ha_address\": \"10.142.83.26\",
\"netmask\": \"255.255.0.0\" },
\"lun\": { \"key\": \"cbd1757b-0580-11e8-bd9d-
00a098d39e12:type=lun,uuid=d208cc7d-80a3-4755-93d4-5db2c38f55a6\" },
\"mtu\": 15000, \"name\": \"aep1\",
\"svm\": { \"key\": \"cbd1757b-0580-11e8-bd9d-
00a178d39e12:type=vserver,uuid=1d1c3198-fc57-11e8-99ca-00a098d38e12\" },
\"vlan\": 10}"

```

The JSON output displays a Job object key that you can use to verify the access endpoint that you created.

3. Verify the access endpoint:

Category	HTTP verb	Path
management-server	GET	/management- server/jobs/{key}

4. Determine whether you have to create a CIFS share or an NFS file share. For creating CIFS shares, follow these substeps:

- Determine whether the CIFS server is configured on your SVM, that is determine whether an Active Directory mapping is created on the SVM.

Category	HTTP verb	Path
storage-provider	GET	/storage- provider/active- directories-mappings

- If the Active Directory mapping is created, take the key, else create the Active Directory mapping on the SVM.

Category	HTTP verb	Path
storage-provider	POST	/storage- provider/active- directories-mappings

Sample cURL

You must enter the details for creating the Active Directory mapping, as the input parameters.

```
curl -X POST "https://<hostname>/api/storage-provider/active-directories-mappings" -H "accept: application/json" -H "Content-Type: application/json" -H "Authorization: Basic <Base64EncodedCredentials>" { \"_links\": {}, \"dns\": \"10.000.000.000\", \"domain\": \"example.com\", \"password\": \"string\", \"svm\": { \"key\": \"9f4ddea-e395-11e9-b660-005056a71be9:type=vserver,uuid=191a554a-f0ce-11e9-b660-005056a71be9\" }, \"username\": \"string\"}"
```

This is a synchronous call and you can verify the creation of the Active Directory mapping in the output. In case of an error, the error message is displayed for you to troubleshoot and rerun the request.

5. Obtain the SVM key for the SVM on which you want to create the CIFS share or the NFS file share, as described in the *Verifying SVMs on clusters* workflow topic.
6. Obtain the key for the Performance Service Level by running the following API and retrieving the key from the response.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/performance-service-levels

You can retrieve the details of the system-defined Performance Service Levels by setting the `system_defined` input parameter to `true`. From the output, obtain the key of the Performance Service Level that you want to apply on the file share.

7. Optionally, obtain the Storage Efficiency Policy key for the Storage Efficiency Policy that you want to apply on the file share by running the following API and retrieving the key from the response.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/storage-efficiency-policies

8. Create the file share. You can create a file share that supports both CIFS and NFS by specifying the access control list and export policy. The following substeps provide information if you want to create a file share for supporting only one of the protocols on the volume. You can also update an NFS file share to include the access control list after you have created the NFS share. For information, see the *Modifying*

storage workloads topic.

- a. For creating only a CIFS share, gather the information about access control list (ACL). For creating the CIFS share, provide valid values for the following input parameters. For each user group that you assign, an ACL is created when a CIFS/SMB share is provisioned. Based on the values you enter for ACL and Active Directory mapping, the access control and mapping are determined for the CIFS share when it is created.

A cURL command with sample values

```
{  
  "access_control": {  
    "acl": [  
      {  
        "permission": "read",  
        "user_or_group": "everyone"  
      }  
    ],  
    "active_directory_mapping": {  
      "key": "3b648c1b-d965-03b7-20da-61b791a6263c"  
    },  
  },  
}
```

- b. For creating only an NFS file share, gather the information about the export policy. For creating the NFS file share, provide valid values for the following input parameters. Based on your values, the export policy is attached with the NFS file share when it is created.

While provisioning the NFS share, you can either create an export policy by providing all the required values or provide the export policy key and reuse an existing export policy. If you want to reuse an export policy for the storage VM, you need to add the export policy key. Unless you know the key, you can retrieve the export policy key by using the `/datacenter/protocols/nfs/export-policies` API. For creating a new policy, you must enter the rules as displayed in the following sample. For the entered rules, the API tries to search for an existing export policy by matching the host, storage VM, and rules. If there is an existing export policy, it is used. Otherwise a new export policy is created.

A cURL command with sample values

```

"export_policy": {
    "key": "7d5a59b3-953a-11e8-8857-
00a098dcc959:type=export_policy,uuid=1460288880641",
    "name_tag": "ExportPolicyNameTag",
    "rules": [
        {
            "clients": [
                {
                    "match": "0.0.0.0/0"
                }
            ]
        }
    ]
}

```

After configuring access control list and export policy, provide the valid values for the mandatory input parameters for both CIFS and NFS file shares:

Storage Efficiency Policy is an optional parameter for creating file shares.

Category	HTTP verb	Path
storage-provider	POST	/storage-provider/file-shares

The JSON output displays a Job object key that you can use to verify the file share that you created. . Verify the file share creation by using the Job object key returned in querying the job:

Category	HTTP verb	Path
management-server	GET	/management-server/jobs/{key}

At the end of the response, you see the key of the file share created.

```

        ],
        "job_results": [
            {
                "name": "fileshareKey",
                "value": "7d5a59b3-953a-11e8-8857-
00a098dcc959:type=volume,uuid=e581c23a-1037-11ea-ac5a-00a098dcc6b6"
            }
        ],
        "_links": {
            "self": {
                "href": "/api/management-server/jobs/06a6148bf9e862df:-2611856e:16e8d47e722:-7f87"
            }
        }
    }
}

```

1. Verify the creation of the file share by running the following API with the returned key:

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/file-shares/{key}

Sample JSON output

You can see that the POST method of /storage-provider/file-shares internally invokes all the APIs required for each of the functions and creates the object. For example, it invokes the /storage-provider/performance-service-levels/ API for assigning the Performance Service Level on the file share.

```

{
    "key": "7d5a59b3-953a-11e8-8857-

Provisioning LUNs by using APIs

You can provision LUNs on your Storage Virtual Machines (SVMs) by using the provisioning APIs provided as a part of Active IQ Unified Manager. This provisioning workflow details the steps for retrieving the keys of the SVMs, Performance Service Levels, and Storage Efficiency Policies before creating the LUN.

The following diagram illustrates the steps in a LUN provisioning workflow.

This workflow assumes that the ONTAP clusters have been added to Unified Manager, and the cluster key has been obtained. The workflow also assumes that the SVMs have already been created on the clusters.

1. Obtain the SVM key for the SVM on which you want to create the LUN, as described in the *Verifying SVMs on clusters* workflow topic.
2. Obtain the key for the Performance Service Level by running the following API and retrieving the key from the response.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/performance-service-levels

You can retrieve the details of the system-defined Performance Service Levels by setting the `system_defined` input parameter to `true`. From the output, obtain the key of the Performance Service Level that you want to apply on the LUN.

3. Optionally, obtain the Storage Efficiency Policy key for the Storage Efficiency Policy that you want to apply on the LUN by running the following API and retrieving the key from the response.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/storage-efficiency-policies

4. Determine if initiator groups (igroups) have been created to grant access to the LUN target that you want to create.

Category	HTTP verb	Path
datacenter	GET	/datacenter/protocols/san/igroups /datacenter/protocols/san/igroups/{key}

You must enter the parameter value for indicating the SVM for which the igrup has authorized access. Additionally, if you want to query a particular igrup, enter the igrup name (key) as an input parameter.

5. In the output, if you can find the igrup that you want to grant access to, obtain the key. Otherwise create the igrup.

Category	HTTP verb	Path
datacenter	POST	/datacenter/protocols/san/igroups

You must enter the details of the igrup that you want to create, as the input parameters. This is a synchronous call and you can verify the igrup creation in the output. In case of an error, a message is displayed for you to troubleshoot and rerun the API.

6. Create the LUN.

Category	HTTP verb	Path
storage-provider	POST	/storage-provider/luns

For creating the LUN, ensure that you have added the retrieved values as mandatory input parameters.

Storage Efficiency Policy is an optional parameter for creating LUNs.

Sample cURL

You must enter all the details of the LUN that you want to create, as the input parameters.

The JSON output displays a Job object key that you can use to verify the LUN that you created.

7. Verify the LUN creation by using the Job object key returned in querying the Job:

Category	HTTP verb	Path
management-server	GET	/management-server/jobs/{key}

At the end of the response, you see the key of the LUN created.

8. Verify the creation of the LUN by running the following API with the returned key:

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/luns/{key}

Sample JSON output

You can see that the POST method of /storage-provider/luns internally invokes all the APIs required for each of the functions and creates the object. For example, it invokes the /storage-provider/performance-service-levels/ API for assigning the Performance Service Level on the LUN.

== Troubleshooting steps for failure in LUN creation or mapping

On completing this workflow, you might still see a failure in your LUN creation. Even if the LUN is created successfully, the LUN mapping with the igroup might fail due to an unavailability of a SAN LIF or access endpoint on the node on which you create the LUN. In case of a failure, you can see the following message:

The nodes <node_name> and <partner_node_name> have no LIFs configured with the iSCSI or FCP protocol for Vserver <server_name>. Use the access-endpoints API to create a LIF for the LUN.

Follow these troubleshooting steps to work around this failure.

1. Create an access endpoint supporting iSCSI/FCP protocol on the SVM on which you tried creating the LUN.

Category	HTTP verb	Path
storage-provider	POST	/storage-provider/access-endpoints

Sample cURL

You must enter the details of the access endpoint that you want to create, as the input parameters.

Ensure that in the input parameter you have added the address to indicate the home node of the LUN and the ha_address to indicate the partner node of the home node. When you run this operation, it creates access endpoints on both the home node and the partner node.

2. Query the job with the Job object key returned in the JSON output to verify that it has run successfully to add the access endpoints on the SVM and that the iSCSI/FCP services have been enabled on the SVM.

Category	HTTP verb	Path
management-server	GET	/management-server/jobs/{key}

Sample JSON output

At the end of the output, you can see the key of the access endpoints created. In the following output, the "name": "accessEndpointKey" value indicates the access endpoint created on the home node of the LUN, for which the key is 9c964258-14ef-11ea-95e2-00a098e32c28. The "name": "accessEndpointHAKey" value indicates the access endpoint created on the partner node of the home node, for which the key is 9d347006-14ef-11ea-8760-00a098e3215f.

3. Modify the LUN to update the igroup mapping. For more information about workflow modification, see "Modifying storage workloads".

Category	HTTP verb	Path
storage-provider	PATCH	/storage-provider/lun/{key}

In the input, specify the igroup key with which you want to update the LUN mapping, along with the LUN key.

Sample cURL

The JSON output displays a Job object key that you can use to verify whether the mapping is successful.

4. Verify the LUN mapping by querying with the LUN key.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/luns/{key}

Sample JSON output

In the output you can see the LUN has been successfully mapped with the igroup (key d19ec2fa-fec7-11e8-b23d-00a098e32c28) with which it was initially provisioned.

Modifying storage workloads by using APIs

Modifying storage workloads consists of updating LUNs or file shares with missing parameters, or changing the existing parameters.

This workflow takes the example of updating Performance Service Levels for LUNs and file shares.

The workflow assumes that the LUN or file share has been provisioned with Performance Service Levels.

Modifying file shares

While modifying a file share, you can update the following parameters:

- Capacity or size.
- Online or offline setting.
- Storage Efficiency Policy.
- Performance Service Level.
- Access control list (ACL) settings.
- Export policy settings. You can also delete export policy parameters and revert the default (empty) export policy rules on the file share.

During a single API run, you can update only one parameter.

This procedure describes adding a Performance Service Level to a file share. You can use the same procedure for updating any other file share property.

1. Obtain the CIFS share or NFS file share key of the file share that you want to update. This API queries all the file shares on your data center. Skip this step if you already know the file share key.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/file-shares

2. View the details of the file share by running the following API with the file share key that you obtained.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/file-shares/{key}

View the details of the file share in the output.

```
"assigned_performance_service_level": {
    "key": null,
    "name": "Unassigned",
    "peak_iops": null,
    "expected_iops": null,
    "_links": {}
},
```

3. Obtain the key for the Performance Service Level that you want to assign on this file share. Currently no policy is assigned to it.

Category	HTTP verb	Path
Performance Service Levels	GET	/storage-provider/performance-service-levels

You can retrieve the details of the system-defined Performance Service Levels by setting the `system_defined` input parameter to `true`. From the output, obtain the key of the Performance Service Level that you want to apply to the file share.

4. Apply the Performance Service Level on the file share.

Category	HTTP verb	Path
Storage Provider	PATCH	/storage-provider/file-shares/{key}

In the input, you must specify only the parameter that you want to update, along with the file share key. In this case, it is the key of the Performance Service Level.

Sample cURL

```
curl -X POST "https://<hostname>/api/storage-provider/file-shares" -H
"accept: application/json" -H "Authorization: Basic
<Base64EncodedCredentials>" -d
"{
  \"performance_service_level\": { \"key\": \"1251e51b-069f-11ea-980d-
  fa163e82bbf2\" },
}
```

The JSON output displays a Job object that you can use to verify the whether the access endpoints on the home and partner nodes have been created successfully.

5. Verify whether the Performance Service Level has been added to the file share by using the Job object key displayed in your output.

Category	HTTP verb	Path
Management Server	GET	/management-server/jobs/{key}

If you query by the ID of the Job object, you see whether the file share is updated successfully. In case of a failure, troubleshoot the failure and run the API again. On successful creation, query the file share to see the modified object:

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/file-shares/{key}

View the details of the file share in the output.

```
"assigned_performance_service_level": {
  "key": "1251e51b-069f-11ea-980d-fa163e82bbf2",
  "name": "Value",
  "peak_iops": 75,
  "expected_iops": 75,
  "_links": {
    "self": {
      "href": "/api/storage-provider/performance-service-
levels/1251e51b-069f-11ea-980d-fa163e82bbf2"
    }
  }
}
```

Updating LUNs

While updating a LUN, you can modify the following parameters:

- Capacity or size
- Online or offline setting
- Storage Efficiency Policy
- Performance Service Level
- LUN map

During a single API run, you can update only one parameter.

This procedure describes adding a Performance Service Level to a LUN. You can use the same procedure for updating any other LUN property.

1. Obtain the LUN key of the LUN that you want to update. This API returns details of all the LUNS in your data center. Skip this step if you already know the LUN key.

Category	HTTP verb	Path
Storage Provider	GET	/storage-provider/luns

2. View the details of the LUN by running the following API with the LUN key that you obtained.

Category	HTTP verb	Path
Storage Provider	GET	/storage-provider/luns/{key}

View the details of the LUN in the output. You can see that there is no Performance Service Level assigned to this LUN.

Sample JSON output

```

"assigned_performance_service_level": {
    "key": null,
    "name": "Unassigned",
    "peak_iops": null,
    "expected_iops": null,
    "_links": {}
},

```

3. Obtain the key for the Performance Service Level that you want to assign to the LUN.

Category	HTTP verb	Path
Performance Service Levels	GET	/storage-provider/performance-service-levels

You can retrieve the details of the system-defined Performance Service Levels by setting the `system_defined` input parameter to `true`. From the output, obtain the key of the Performance Service Level that you want to apply on the LUN.

4. Apply the Performance Service Level on the LUN.

Category	HTTP verb	Path
Storage Provider	PATCH	<code>/storage-provider/lun/{key}</code>

In the input, you must specify only the parameter that you want to update, along with the LUN key. In this case it is the key of the Performance Service Level.

Sample cURL

```
curl -X PATCH "https://<hostname>/api/storage-provider/luns/7d5a59b3-953a-11e8-8857-00a098dcc959" -H "accept: application/json" -H "Content-Type: application/json" -H "Authorization: Basic <Base64EncodedCredentials>" -d "{\"performance_service_level\": { \"key\": \"1251e51b-069f-11ea-980d-fa163e82bbf2\" }}
```

The JSON output displays a Job object key that you can use to verify the LUN that you updated.

5. View the details of the LUN by running the following API with the LUN key that you obtained.

Category	HTTP verb	Path
Storage Provider	GET	<code>/storage-provider/luns/{key}</code>

View the details of the LUN in the output. You can see that the Performance Service Level is assigned to this LUN.

Sample JSON output

```

"assigned_performance_service_level": {
  "key": "1251e51b-069f-11ea-980d-fa163e82bbf2",
  "name": "Value",
  "peak_iops": 75,
  "expected_iops": 75,
  "_links": {
    "self": {
      "href": "/api/storage-provider/performance-service-
levels/1251e51b-069f-11ea-980d-fa163e82bbf2"
    }
  }
}

```

Modifying an NFS file share by using APIs to support CIFS

You can modify an NFS file share to support CIFS protocol. During file share creation, it is possible to specify both access control list (ACL) parameters and export policy rules for the same file share. However, if you want to enable CIFS on the same volume where you created an NFS file share, you can update the ACL parameters on that file share to support CIFS.

What you'll need

1. An NFS file share must have been created with only the export policy details. For information, see *Managing file shares* and *Modifying storage workloads*.
2. You must have the file share key to run this operation. For information about viewing file share details and retrieving the file share key by using the Job ID, see *Provisioning CIFS and NFS file shares*.

This is applicable for an NFS file share that you created by adding only export policy rules and not ACL parameters. You modify the NFS file share to include the ACL parameters.

Steps

1. On the NFS file share, perform a PATCH operation with the ACL details for allowing CIFS access.

Category	HTTP verb	Path
storage-provider	PATCH	/storage-provider/file- shares

Sample cURL

Based on the access privileges you assign to the user group, as displayed in the following sample, an ACL is created and assigned to the file share.

```
{
  "access_control": {
    "acl": [
      {
        "permission": "read",
        "user_or_group": "everyone"
      }
    ],
    "active_directory_mapping": {
      "key": "3b648c1b-d965-03b7-20da-61b791a6263c"
    }
  }
}
```

Sample JSON output

The operation returns the Job ID of the Job that runs the update.

2. Verify whether the parameters have been added correctly by querying the file share details for the same file share.

Category	HTTP verb	Path
storage-provider	GET	/storage-provider/file-shares/{key}

Sample JSON output

```
"access_control": {
  "acl": [
    {
      "user_or_group": "everyone",
      "permission": "read"
    }
  ],
  "export_policy": {
    "id": 1460288880641,
    "key": "7d5a59b3-953a-11e8-8857-00a098dcc959:type=export_policy,uuid=1460288880641",
    "name": "default",
    "rules": [
      {
        "anonymous_user": "65534",
        "clients": [
          {
            "match": "0.0.0.0/0"
          }
        ],
        "groups": [
          "Everyone"
        ],
        "users": [
          "Everyone"
        ]
      }
    ]
  }
}
```

```

        "index": 1,
        "protocols": [
            "nfs3",
            "nfs4"
        ],
        "ro_rule": [
            "sys"
        ],
        "rw_rule": [
            "sys"
        ],
        "superuser": [
            "none"
        ]
    },
    {
        "anonymous_user": "65534",
        "clients": [
            {
                "match": "0.0.0.0/0"
            }
        ],
        "index": 2,
        "protocols": [
            "cifs"
        ],
        "ro_rule": [
            "ntlm"
        ],
        "rw_rule": [
            "ntlm"
        ],
        "superuser": [
            "none"
        ]
    }
],
"_links": {
    "self": {
        "href": "/api/datacenter/protocols/nfs/export-
policies/7d5a59b3-953a-11e8-8857-
00a098dcc959?type=export_policy,uuid=1460288880641"
    }
}
}

```

```
  "_links": {
    "self": {
      "href": "/api/storage-provider/file-shares/7d5a59b3-953a-11e8-8857-00a098dcc959?type=volume,uuid=e581c23a-1037-11ea-ac5a-00a098dcc6b6"
    }
  }
```

You can see the ACL assigned along with the export policy to the same file share.
