This document describes how NetApp HCI can be designed to host artificial intelligence (AI) inferencing workloads at edge data center locations. The design is based on NVIDIA T4 GPU-powered NetApp HCI compute nodes, an NVIDIA Triton Inference Server, and a Kubernetes infrastructure built using NVIDIA DeepOps. The design also establishes the data pipeline between the core and edge data centers and illustrates implementation to complete the data lifecycle path.

Modern applications that are driven by AI and machine learning (ML) have pushed the limits of the internet. End users and devices demand access to applications, data, and services at any place and any time, with minimal latency. To meet these demands, data centers are moving closer to their users to boost performance, reduce back-and-forth data transfer, and provide cost-effective ways to meet user requirements.

In the context of AI, the core data center is a platform that provides centralized services, such as machine learning and analytics, and the edge data centers are where the real-time production data is subject to inferencing. These edge data centers are usually connected to a core data center. They provide end-user services and serve as a staging layer for data generated by IoT devices that need additional processing and that is too time sensitive to be transmitted back to a centralized core.

This document describes a reference architecture for AI inferencing that uses NetApp HCI as the base platform.

Customer Value

NetApp HCI offers differentiation in the hyperconverged market for this inferencing solution, including the following advantages:

- A disaggregated architecture allows independent scaling of compute and storage and lowers the virtualization licensing costs and performance tax on independent NetApp HCI storage nodes.
- NetApp Element storage provides quality of service (QoS) for each storage volume, which provides guaranteed storage performance for workloads on NetApp HCI. Therefore, adjacent workloads do not negatively affect inferencing performance.
- A data fabric powered by NetApp allows data to be replicated from core to edge to cloud data centers, which moves data closer to where application needs it.
- With a data fabric powered by NetApp and NetApp FlexCache software, AI deep learning models trained on NetApp ONTAP AI can be accessed from NetApp HCI without having to export the model.
- NetApp HCI can host inference servers on the same infrastructure concurrently with multiple workloads, either virtual-machine (VM) or container-based, without performance degradation.
- NetApp HCI is certified as NVIDIA GPU Cloud (NGC) ready for NVIDIA AI containerized applications.
- NGC-ready means that the stack is validated by NVIDIA, is purpose built for AI, and enterprise support is available through NGC Support Services.
- With its extensive AI portfolio, NetApp can support the entire spectrum of AI use cases from edge to core to cloud, including ONTAP AI for training and inferencing, Cloud Volumes Service and Azure NetApp Files for training in the cloud, and inferencing on the edge with NetApp HCI.

Next: Use Cases
Use Cases

Although all applications today are not AI driven, they are evolving capabilities that allow them to access the immense benefits of AI. To support the adoption of AI, applications need an infrastructure that provides them with the resources needed to function at an optimum level and support their continuing evolution.

For AI-driven applications, edge locations act as a major source of data. Available data can be used for training when collected from multiple edge locations over a period of time to form a training dataset. The trained model can then be deployed back to the edge locations where the data was collected, enabling faster inferencing without the need to repeatedly transfer production data to a dedicated inferencing platform.

The NetApp HCI AI inferencing solution, powered by NetApp H615c compute nodes with NVIDIA T4 GPUs and NetApp cloud-connected storage systems, was developed and verified by NetApp and NVIDIA. NetApp HCI simplifies the deployment of AI inferencing solutions at edge data centers by addressing areas of ambiguity, eliminating complexities in the design and ending guesswork.

This solution gives IT organizations a prescriptive architecture that:

- Enables AI inferencing at edge data centers
- Optimizes consumption of GPU resources
- Provides a Kubernetes-based inferencing platform for flexibility and scalability
- Eliminates design complexities

Edge data centers manage and process data at locations that are very near to the generation point. This proximity increases the efficiency and reduces the latency involved in handling data. Many vertical markets have realized the benefits of an edge data center and are heavily adopting this distributed approach to data processing.

The following table lists the edge verticals and applications.

<table>
<thead>
<tr>
<th>Vertical</th>
<th>Applications</th>

### Vertical | Applications
---|---
Manufacturing | Quality control, assembly-line monitoring, and defect identification
Customer service | Customer service automation to analyze and triage inquiries (phone, email, and social media)
Agriculture | Intelligent farm operation and activity planning, to optimize fertilizer and herbicide application

---

**Target Audience**

The target audience for the solution includes the following groups:

- Data scientists
- IT architects
- Field consultants
- Professional services
- IT managers
- Anyone else who needs an infrastructure that delivers IT innovation and robust data and application services at edge locations

---

**Architecture**

**Solution Technology**

This solution is designed with a NetApp HCI system that contains the following components:

- Two H615c compute nodes with NVIDIA T4 GPUs
- Two H410c compute nodes
- Two H410s storage nodes
- Two Mellanox SN2010 10GbE/25GbE switches

**Architectural Diagram**

The following diagram illustrates the solution architecture for the NetApp HCI AI inferencing solution.
The following diagram illustrates the virtual and physical elements of this solution.

A VMware infrastructure is used to host the management services required by this inferencing solution. These services do not need to be deployed on a dedicated infrastructure; they can coexist with any existing workloads. The NetApp Deployment Engine (NDE) uses the H410c and H410s nodes to deploy the VMware infrastructure.

After NDE has completed the configuration, the following components are deployed as VMs in the virtual infrastructure:
• **Deployment Jump VM.** Used to automate the deployment of NVIDIA DeepOps. See [NVIDIA DeepOps](#) and storage management using NetApp Trident.

• **ONTAP Select.** An instance of ONTAP Select is deployed to provide NFS file services and persistent storage to the AI workload running on Kubernetes.

• **Kubernetes Masters.** During deployment, three VMs are installed and configured with a supported Linux distribution and configured as Kubernetes master nodes. After the management services have been set up, two H615c compute nodes with NVIDIA T4 GPUs are installed with a supported Linux distribution. These two nodes function as the Kubernetes worker nodes and provide the infrastructure for the inferencing platform.

### Hardware Requirements

The following table lists the hardware components that are required to implement the solution. The hardware components that are used in any particular implementation of the solution might vary based on customer requirements.

<table>

**Next: Design Considerations**

**Design Considerations**

**Network Design**

The switches used to handle the NetApp HCI traffic require a specific configuration for successful deployment.

Consult the NetApp HCI Network Setup Guide for the physical cabling and switch details. This solution uses a two-cable design for compute nodes. Optionally, compute nodes can be configured in a six-node cable design affording options for deployment of compute nodes.

The diagram under Architecture depicts the network topology of this NetApp HCI solution with a two-cable design for the compute nodes.

**Compute Design**

The NetApp HCI compute nodes are available in two form factors, half-width and full-width, and in two rack unit sizes, 1 RU and 2 RU. The 410c nodes used in this solution are half-width and 1 RU and are housed in a chassis that can hold a maximum of four such nodes. The other compute node that is used in this solution is the H615c, which is a full-width node, 1 RU in size. The H410c nodes are based on Intel Skylake processors, and the H615c nodes are based on the second-generation Intel Cascade Lake processors. NVIDIA GPUs can be added to the H615c nodes, and each node can host a maximum of three NVIDIA Tesla T4 16GB GPUs.

The H615c nodes are the latest series of compute nodes for NetApp HCI and the second series that can support GPUs. The first model to support GPUs is the H610c node (full width, 2RU), which can support two...
NVIDIA Tesla M10 GPUs.

In this solution, H615c nodes are preferred over H610c nodes because of the following advantages:

- Reduced data center footprint, critical for edge deployments
- Support for a newer generation of GPUs designed for faster inferencing
- Reduced power consumption
- Reduced heat dissipation

**NVIDIA T4 GPUs**

The resource requirements of inferencing are nowhere close to those of training workloads. In fact, most modern hand-held devices are capable of handling small amounts of inferencing without powerful resources like GPUs. However, for mission-critical applications and data centers that are dealing with a wide variety of applications that demand very low inferencing latencies while subject to extreme parallelization and massive input batch sizes, the GPUs play a key role in reducing inference time and help to boost application performance.

The NVIDIA Tesla T4 is an x16 PCIe Gen3 single-slot low-profile GPU based on the Turing architecture. The T4 GPUs deliver universal inference acceleration that spans applications such as image classification and tagging, video analytics, natural language processing, automatic speech recognition, and intelligent search. The breadth of the Tesla T4’s inferencing capabilities enables it to be used in enterprise solutions and edge devices.

These GPUs are ideal for deployment in edge infrastructures due to their low power consumption and small PCIe form factor. The size of the T4 GPUs enables the installation of two T4 GPUs in the same space as a double-slot full-sized GPU. Although they are small, with 16GB memory, the T4s can support large ML models or run inference on multiple smaller models simultaneously.

The Turing-based T4 GPUs include an enhanced version of Tensor Cores and support a full range of precisions for inferencing FP32, FP16, INT8, and INT4. The GPU includes 2,560 CUDA cores and 320 Tensor Cores, delivering up to 130 tera operations per second (TOPS) of INT8 and up to 260 TOPS of INT4 inferencing performance. When compared to CPU-based inferencing, the Tesla T4, powered by the new Turing Tensor Cores, delivers up to 40 times higher inference performance.

The Turing Tensor Cores accelerate the matrix-matrix multiplication at the heart of neural network training and inferencing functions. They particularly excel at inference computations in which useful and relevant information can be inferred and delivered by a trained deep neural network based on a given input.

The Turing GPU architecture inherits the enhanced Multi-Process Service (MPS) feature that was introduced in the Volta architecture. Compared to Pascal-based Tesla GPUs, MPS on Tesla T4 improves inference performance for small batch sizes, reduces launch latency, improves QoS, and enables the servicing of higher numbers of concurrent client requests.

The NVIDIA T4 GPU is a part of the NVIDIA AI Inference Platform that supports all AI frameworks and provides comprehensive tooling and integrations to drastically simplify the development and deployment of advanced AI.

**Storage Design: Element Software**

NetApp Element software powers the storage of the NetApp HCI systems. It delivers agile automation through scale-out flexibility and guaranteed application performance to accelerate new services.
Storage nodes can be added to the system non-disruptively in increments of one, and the storage resources are made available to the applications instantly. Every new node added to the system delivers a precise amount of additional performance and capacity to a usable pool. The data is automatically load balanced in the background across all nodes in the cluster, maintaining even utilization as the system grows.

Element software supports the NetApp HCI system to comfortably host multiple workloads by guaranteeing QoS to each workload. By providing fine-grained performance control with minimum, maximum, and burst settings for each workload, the software allows well-planned consolidations while protecting application performance. It decouples performance from capacity and allows each volume to be allocated with a specific amount of capacity and performance. These specifications can be modified dynamically without any interruption to data access.

As illustrated in the following figure, Element software integrates with NetApp ONTAP to enable data mobility between NetApp storage systems that are running different storage operating systems. Data can be moved from the Element software to ONTAP or vice versa by using NetApp SnapMirror technology. Element uses the same technology to provide cloud connectivity by integrating with NetApp Cloud Volumes ONTAP, which enables data mobility from the edge to the core and to multiple public cloud service providers.

In this solution, the Element-backed storage provides the storage services that are required to run the workloads and applications on the NetApp HCI system.

Storage Design: ONTAP Select

NetApp ONTAP Select introduces a software-defined data storage service model on top of NetApp HCI. It builds on NetApp HCI capabilities, adding a rich set of file and data services to the HCI platform while extending the data fabric.

Although ONTAP Select is an optional component for implementing this solution, it does provide a host of
benefits, including data gathering, protection, mobility, and so on, that are extremely useful in the context of the overall AI data lifecycle. It helps to simplify several day-to-day challenges for data handling, including ingestion, collection, training, deployment, and tiering.

ONTAP Select can run as a VM on VMware and still bring in most of the ONTAP capabilities that are available when it is running on a dedicated FAS platform, such as the following:

- Support for NFS and CIFS
- NetApp FlexClone technology
- NetApp FlexCache technology
- NetApp ONTAP FlexGroup volumes
- NetApp SnapMirror software

ONTAP Select can be used to leverage the FlexCache feature, which helps to reduce data-read latencies by caching frequently read data from a back-end origin volume, as is shown in the following figure. In the case of high-end inferencing applications with a lot of parallelization, multiple instances of the same model are deployed across the inferencing platform, leading to multiple reads of the same model. Newer versions of the trained model can be seamlessly introduced to the inferencing platform by verifying that the desired model is available in the origin or source volume.
NetApp Trident

NetApp Trident is an open-source dynamic storage orchestrator that allows you to manage storage resources across all major NetApp storage platforms. It integrates with Kubernetes natively so that persistent volumes (PVs) can be provisioned on demand with native Kubernetes interfaces and constructs. Trident enables microservices and containerized applications to use enterprise-class storage services such as QoS, storage efficiencies, and cloning to meet the persistent storage demands of applications.

Containers are among the most popular methods of packaging and deploying applications, and Kubernetes is one of the most popular platforms for hosting containerized applications. In this solution, the inferencing platform is built on top of a Kubernetes infrastructure.

Trident currently supports storage orchestration across the following platforms:

- ONTAP: NetApp AFF, FAS, and Select
- Element software: NetApp HCI and NetApp SolidFire all-flash storage
- NetApp SANtricity software: E-Series and EF-series
- Cloud Volumes ONTAP
- Azure NetApp Files
- NetApp Cloud Volumes Service: AWS and Google Cloud

Trident is a simple but powerful tool to enable storage orchestration not just across multiple storage platforms, but also across the entire spectrum of the AI data lifecycle, ranging from the edge to the core to the cloud.

Trident can be used to provision a PV from a NetApp Snapshot copy that makes up the trained model. The following figure illustrates the Trident workflow in which a persistent volume claim (PVC) is created by referring to an existing Snapshot copy. Following this, Trident creates a volume by using the Snapshot copy.
This method of introducing trained models from a Snapshot copy supports robust model versioning. It simplifies the process of introducing newer versions of models to applications and switching inferencing between different versions of the model.

**NVIDIA DeepOps**

NVIDIA DeepOps is a modular collection of Ansible scripts that can be used to automate the deployment of a Kubernetes infrastructure. There are multiple deployment tools available that can automate the deployment of a Kubernetes cluster. In this solution, DeepOps is the preferred choice because it does not just deploy a Kubernetes infrastructure, it also installs the necessary GPU drivers, NVIDIA Container Runtime for Docker (nvidia-docker2), and various other dependencies for GPU-accelerated work. It encapsulates the best practices for NVIDIA GPUs and can be customized or run as individual components as needed.

DeepOps internally uses Kubespray to deploy Kubernetes, and it is included as a submodule in DeepOps. Therefore, common Kubernetes cluster management operations such as adding nodes, removing nodes, and cluster upgrades should be performed using Kubespray.

A software based L2 LoadBalancer using MetalLb and an Ingress Controller based on NGINX are also deployed as part of this solution by using the scripts that are available with DeepOps.

In this solution, three Kubernetes master nodes are deployed as VMs, and the two H615c compute nodes with NVIDIA Tesla T4 GPUs are set up as Kubernetes worker nodes.

**NVIDIA GPU Operator**

The GPU operator deploys the NVIDIA k8s-device-plugin for GPU support and runs the NVIDIA drivers as containers. It is based on the Kubernetes operator framework, which helps to automate the management of all NVIDIA software components that are needed to provision GPUs. The components include NVIDIA drivers, Kubernetes device plug-in for GPUs, the NVIDIA container runtime, and automatic node labeling, which is used in tandem with Kubernetes Node Feature Discovery.
The GPU operator is an important component of the NVIDIA EGX software-defined platform that is designed to make large-scale hybrid-cloud and edge operations possible and efficient. It is specifically useful when the Kubernetes cluster needs to scale quickly—for example, when provisioning additional GPU-based worker nodes and managing the lifecycle of the underlying software components. Because the GPU operator runs everything as containers, including NVIDIA drivers, administrators can easily swap various components by simply starting or stopping containers.

**NVIDIA Triton Inference Server**

NVIDIA Triton Inference Server (Triton Server) simplifies the deployment of AI inferencing solutions in production data centers. This microservice is specifically designed for inferencing in production data centers. It maximizes GPU utilization and integrates seamlessly into DevOps deployments with Docker and Kubernetes.

Triton Server provides a common solution for AI inferencing. Therefore, researchers can focus on creating high-quality trained models, DevOps engineers can focus on deployment, and developers can focus on applications without the need to redesign the platform for each AI-powered application.

Here are some of the key features of Triton Server:

- **Support for multiple frameworks.** Triton Server can handle a mix of models, and the number of models is limited only by system disk and memory resources. It can support the TensorRT, TensorFlow GraphDef, TensorFlow SavedModel, ONNX, PyTorch, and Caffe2 NetDef model formats.
- *Concurrent model execution.* Multiple models or multiple instances of the same model can be run simultaneously on a GPU.
- **Multi-GPU support.** Triton Server can maximize GPU utilization by enabling inference for multiple models on one or more GPUs.
- **Support for batching.** Triton Server can accept requests for a batch of inputs and respond with the corresponding batch of outputs. The inference server supports multiple scheduling and batching algorithms that combine individual inference requests together to improve inference throughput. Batching algorithms are available for both stateless and stateful applications and need to be used appropriately. These scheduling and batching decisions are transparent to the client that is requesting inference.
- **Ensemble support.** An ensemble is a pipeline with multiple models with connections of input and output tensors between those models. An inference request can be made to an ensemble, which results in the execution of the complete pipeline.
- **Metrics.** Metrics are details about GPU utilization, server throughput, server latency, and health for auto scaling and load balancing.

NetApp HCI is a hybrid multi-cloud infrastructure that can host multiple workloads and applications, and the Triton Inference Server is well equipped to support the inferencing requirements of multiple applications.

In this solution, Triton Server is deployed on the Kubernetes cluster using a deployment file. With this method, the default configuration of Triton Server can be overridden and customized as required. Triton Server also provides an inference service using an HTTP or GRPC endpoint, allowing remote clients to request inferencing for any model that is being managed by the server.

A Persistent Volume is presented via NetApp Trident to the container that runs the Triton Inference Server and this persistent volume is configured as the model repository for the Inference server.

The Triton Inference Server is deployed with varying sets of resources using Kubernetes deployment files, and each server instance is presented with a LoadBalancer front end for seamless scalability. This approach also illustrates the flexibility and simplicity with which resources can be allocated to the inferencing workloads.

Next: Deploying NetApp HCI – AI Inferencing at the Edge
Overview

This section describes the steps required to deploy the AI inferencing platform using NetApp HCI. The following list provides the high-level tasks involved in the setup:

1. Configure network switches
2. Deploy the VMware virtual infrastructure on NetApp HCI using NDE
3. Configure the H615c compute nodes to be used as K8 worker nodes
4. Set up the deployment jump VM and K8 master VMs
5. Deploy a Kubernetes cluster with NVIDIA DeepOps
6. Deploy ONTAP Select within the virtual infrastructure
7. Deploy NetApp Trident
8. Deploy NVIDIA Triton inference Server
9. Deploy the client for the Triton inference server
10. Collect inference metrics from the Triton inference server

Next: Configure Network Switches

Configure Network Switches (Automated Deployment)

Prepare Required VLAN IDs

The following table lists the necessary VLANs for deployment, as outlined in this solution validation. You should configure these VLANs on the network switches prior to executing NDE.

<table>
<thead>
<tr>
<th>Network Segment</th>
<th>Details</th>
<th>VLAN ID</th>
</tr>

*Only for Mellanox switches

Switch Configuration

This solution uses Mellanox SN2010 switches running Onyx. The Mellanox switches are configured using an
Ansible playbook. Prior to running the Ansible playbook, you should perform the initial configuration of the switches manually:

1. Install and cable the switches to the uplink switch, compute, and storage nodes.
2. Power on the switches and configure them with the following details:
   a. Host name
   b. Management IP and gateway
   c. NTP
3. Log into the Mellanox switches and run the following commands:

   ```
   configuration write to pre-ansible
   configuration write to post-ansible
   ```

   The `pre-ansible` configuration file created can be used to restore the switch’s configuration to the state before the Ansible playbook execution.

   The switch configuration for this solution is stored in the `post-ansible` configuration file.

4. The configuration playbook for Mellanox switches that follows best practices and requirements for NetApp HCI can be downloaded from the [NetApp HCI Toolkit](#).

   The HCI Toolkit also provides a playbook to setup Cisco Nexus switches with similar best practices and requirements for NetApp HCI.

   Additional guidance on populating the variables and executing the playbook is available in the respective switch README.md file.

5. Fill out the credentials to access the switches and variables needed for the environment. The following text is a sample of the variable file for this solution.

   ```
   # vars file for nar_hci_mellanox_deploy
   #These set of variables will setup the Mellanox switches for NetApp HCI that uses a 2-cable compute connectivity option.
   #Ansible connection variables for mellanox
   ansible_connection: network_cli
   ansible_network_os: onyx
   #-------------------
   # Primary Variables
   #-------------------
   #Necessary VLANs for Standard NetApp HCI Deployment [native, Management, iSCSI_Storage, vMotion, VM_Network, IPL]
   #Any additional VLANs can be added to this in the prescribed format below
   netapp_hci_vlans:
   - {vlan_id: 2 , vlan_name: "Native" }
   - {vlan_id: 3488 , vlan_name: "IB-Management" }
   ```
- {vlan_id: 3490, vlan_name: "iSCSI_Storage"}
- {vlan_id: 3489, vlan_name: "vMotion"}
- {vlan_id: 3491, vlan_name: "NFS"}
- {vlan_id: 3487, vlan_name: "App_Network"}
- {vlan_id: 4000, vlan_name: "IPL"}

# Modify the VLAN IDs to suit your environment

# Spanning-tree protocol type for uplink connections.
The valid options are 'network' and 'normal'; selection depends on the uplink switch model.
uplink_stp_type: network

#----------------------
# IPL variables
#----------------------

# Inter-Peer Link Portchannel
# ipl_portchannel to be defined in the format - Po100
ipl_portchannel: Po100

# Inter-Peer Link Addresses
# The IPL IP address should not be part of the management network. This is typically a private network
ipl_ipaddr_a: 10.0.0.1
ipl_ipaddr_b: 10.0.0.2

# Define the subnet mask in CIDR number format. Eg: For subnet /22, use
ipl_ip_subnet: 22
ipl_ip_subnet: 24

# List the storage Bond1G interfaces and their description in list of dictionaries format

storage_mgmt_interfaces:
- {members: "Ethx/y", description: "HCI_Storage_Node_01"}
- {members: "Ethx/y", description: "HCI_Storage_Node_02"}
# In case of additional storage nodes, add them here

# LACP load balancing algorithm for IP hash method
# Possible options are: 'destination-mac', 'destination-ip', 'destination-port', 'source-mac', 'source-ip', 'source-port', 'source-destination-mac', 'source-destination-ip', 'source-destination-port'
# This variable takes multiple options in a single go
# For eg: if you want to configure load to be distributed in the port-channel based on the traffic source and destination IP address and port number, use 'source-destination-ip source-destination-port'
# By default, Mellanox sets it to source-destination-mac. Enter the values below only if you intend to configure any other load balancing algorithm
# Make sure the load balancing algorithm that is set here is also replicated on the host side
# Recommended algorithm is source-destination-ip source-destination-port
#Fill the lacp_load_balance variable only if you are using configuring interfaces on compute nodes in bond or LAG with LACP

lacp_load_balance: "source-destination-ip source-destination-port"

#Compute Interface details

#Members to be defined with Eth in the format. Eg: Eth1/1

#Fill the mlag_id field only if you intend to configure interfaces of compute nodes into bond or LAG with LACP

#In case you do not intend to configure LACP on interfaces of compute nodes, either leave the mlag_id field unfilled or comment it or enter NA in the mlag_id field

#In case you have a mixed architecture where some compute nodes require LACP and some don't,

#1. Fill the mlag_id field with appropriate MLAG ID for interfaces that connect to compute nodes requiring LACP

#2. Either fill NA or leave the mlag_id field blank or comment it for interfaces connecting to compute nodes that do not require LACP

#Only numerical digits between 100 to 1000 allowed for mlag_id.

#Operational link speed [variable 'speed' below] to be defined in terms of bytes.

#For 10 Gigabyte operational speed, define 10G. [Possible values - 10G and 25G]

#Interface descriptions append compute node port numbers assuming all Compute Nodes' Port D --> Mellanox Switch A and all Compute Nodes' Port E --> Mellanox Switch B

#List the compute interfaces, their speed, MLAG IDs and their description in list of dictionaries format

compute_interfaces:

- members: "Eth1/7" #Compute Node for ESXi, setup by NDE
description: "HCI_Compute_Node_01"

  mlag_id: #Fill the mlag_id only if you wish to use LACP on interfaces towards compute nodes
  speed: 25G

- members: "Eth1/8" #Compute Node for ESXi, setup by NDE
description: "HCI_Compute_Node_02"

  mlag_id: #Fill the mlag_id only if you wish to use LACP on interfaces towards compute nodes
  speed: 25G

#In case of additional compute nodes, add them here in the same format as above-

- members: "Eth1/9" #Compute Node for Kubernetes Worker node
description: "HCI_Compute_Node_01"

  mlag_id: 109 #Fill the mlag_id only if you wish to use LACP on interfaces towards compute nodes
  speed: 10G

- members: "Eth1/10" #Compute Node for Kubernetes Worker node
description: "HCI_Compute_Node_02"

  mlag_id: 110 #Fill the mlag_id only if you wish to use LACP on
interfaces towards compute nodes
speed: 10G
# Uplink Switch LACP support
# Possible options are 'yes' and 'no' - Set to 'yes' only if your uplink switch supports LACP
uplink_switch_lacp: <<yes or no>>
# Uplink Interface details
# Members to be defined with Eth in the format. Eg: Eth1/1
# Only numerical digits between 100 to 1000 allowed for mlag_id.
# Operational link speed [variable 'speed' below] to be defined in terms of bytes.
# For 10 Gigabyte operational speed, define 10G. [Possible values in Mellanox are 1G, 10G and 25G]
# List the uplink interfaces, their description, MLAG IDs and their speed in list of dictionaries format
uplink_interfaces:
- members: "Eth1/18"
  description_switch_a: "SwitchA:Ethx/y -> Uplink_Switch:Ethx/y"
  description_switch_b: "SwitchB:Ethx/y -> Uplink_Switch:Ethx/y"
  mlag_id: 118  # Fill the mlag_id only if 'uplink_switch_lacp' is set to 'yes'
speed: 10G
mtu: 1500

The fingerprint for the switch’s key must match with that present in the host machine from where the playbook is being executed. To ensure this, add the key to /root/.ssh/known_host or any other appropriate location.

Rollback the Switch Configuration

1. In case of any timeout failures or partial configuration, run the following command to roll back the switch to the initial state.

   configuration switch-to pre-ansible

   This operation requires a reboot of the switch.

2. Switch the configuration to the state before running the Ansible playbook.

   configuration delete post-ansible

3. Delete the post-ansible file that had the configuration from the Ansible playbook.
4. Create a new file with the same name post-ansible, write the pre-ansible configuration to it, and switch to the new configuration to restart configuration.

**IP Address Requirements**

The deployment of the NetApp HCI inferencing platform with VMware and Kubernetes requires multiple IP addresses to be allocated. The following table lists the number of IP addresses required. Unless otherwise indicated, addresses are assigned automatically by NDE.

<table>
<thead>
<tr>
<th>IP Address Quantity</th>
<th>Details</th>
<th>VLAN ID</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>One per storage and compute node*</td>
<td>HCI terminal user interface (TUI) addresses</td>
<td>16</td>
<td></td>
</tr>
<tr>
<td>One per vCenter Server (VM)</td>
<td>vCenter Server management address</td>
<td>3488</td>
<td></td>
</tr>
<tr>
<td>One per management node (VM)</td>
<td>Management node IP address</td>
<td></td>
<td></td>
</tr>
<tr>
<td>One per ESXi host</td>
<td>ESXi compute management addresses</td>
<td></td>
<td></td>
</tr>
<tr>
<td>One per storage/witness node</td>
<td>NetApp HCI storage node management addresses</td>
<td></td>
<td></td>
</tr>
<tr>
<td>One per storage cluster</td>
<td>Storage cluster management address</td>
<td></td>
<td></td>
</tr>
<tr>
<td>One per ESXi host</td>
<td>VMware vMotion address</td>
<td>3489</td>
<td></td>
</tr>
<tr>
<td>Two per ESXi host</td>
<td>ESXi host initiator address for iSCSI storage traffic</td>
<td>3490</td>
<td></td>
</tr>
<tr>
<td>Two per storage node</td>
<td>Storage node target address for iSCSI storage traffic</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Two per storage cluster</td>
<td>Storage cluster target address for iSCSI storage traffic</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Two for mNode</td>
<td>mNode iSCSI storage access</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following IPs are assigned manually when the respective components are configured.
<table>
<thead>
<tr>
<th>IP Address Quantity</th>
<th>Details</th>
<th>VLAN ID</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>One for Deployment Jump Management network</td>
<td>Deployment Jump VM to execute Ansible playbooks and configure other parts of the system – management connectivity</td>
<td>3488</td>
<td></td>
</tr>
<tr>
<td>One per Kubernetes master node – management network</td>
<td>Kubernetes master node VMs (three nodes)</td>
<td>3488</td>
<td></td>
</tr>
<tr>
<td>One per Kubernetes worker node – management network</td>
<td>Kubernetes worker nodes (two nodes)</td>
<td>3488</td>
<td></td>
</tr>
<tr>
<td>One per Kubernetes worker node – NFS network</td>
<td>Kubernetes worker nodes (two nodes)</td>
<td>3491</td>
<td></td>
</tr>

<td></td>
</tr>
<tr>
<td>At least two for Triton Inference Server Load Balancer – application network</td>
<td>Load balancer IP range for Kubernetes load balancer service</td>
<td>3487</td>
<td></td>
</tr>
</tbody>
</table>

*This validation requires the initial setup of the first storage node TUI address. NDE automatically assigns the TUI address for subsequent nodes.

**DNS and Timekeeping Requirement**

Depending on your deployment, you might need to prepare DNS records for your NetApp HCI system. NetApp HCI requires a valid NTP server for timekeeping; you can use a publicly available time server if you do not have one in your environment.

This validation involves deploying NetApp HCI with a new VMware vCenter Server instance using a fully qualified domain name (FQDN). Before deployment, you must have one Pointer (PTR) record and one Address (A) record created on the DNS server.

Next: Virtual Infrastructure with Automated Deployment

**Deploy VMware Virtual Infrastructure on NetApp HCI with NDE (Automated Deployment)**
NDE Deployment Prerequisites

Consult the NetApp HCI Prerequisites Checklist to see the requirements and recommendations for NetApp HCI before you begin deployment.

1. Network and switch requirements and configuration
2. Prepare required VLAN IDs
3. Switch configuration
4. IP Address Requirements for NetApp HCI and VMware
5. DNS and time-keeping requirements
6. Final preparations

NDE Execution

Before you execute the NDE, you must complete the rack and stack of all components, configuration of the network switches, and verification of all prerequisites. You can execute NDE by connecting to the management address of a single storage node if you plan to allow NDE to automatically configure all addresses.

NDE performs the following tasks to bring an HCI system online:

1. Installs the storage node (NetApp Element software) on a minimum of two storage nodes.
2. Installs the VMware hypervisor on a minimum of two compute nodes.
3. Installs VMware vCenter to manage the entire NetApp HCI stack.
4. Installs and configures the NetApp storage management node (mNode) and NetApp Monitoring Agent.

This validation uses NDE to automatically configure all addresses. You can also set up DHCP in your environment or manually assign IP addresses for each storage node and compute node. These steps are not covered in this guide.

As mentioned previously, this validation uses a two-cable configuration for compute nodes.

Detailed steps for the NDE are not covered in this document.

For step-by-step guidance on completing the deployment of the base NetApp HCI platform, see the Deployment guide.

5. After NDE has finished, login to the vCenter and create a Distributed Port Group NetApp HCI VDS 01-NFS_Network for the NFS network to be used by ONTAP Select and the application.

Next: Configure NetApp H615c (Manual Deployment)

Configure NetApp H615c (Manual Deployment)

In this solution, the NetApp H615c compute nodes are configured as Kubernetes worker nodes. The Inferencing workload is hosted on these nodes.

Deploying the compute nodes involves the following tasks:

• Install Ubuntu 18.04.4 LTS.
• Configure networking for data and management access.
• Prepare the Ubuntu instances for Kubernetes deployment.

Install Ubuntu 18.04.4 LTS

The following high-level steps are required to install the operating system on the H615c compute nodes:

1. Download Ubuntu 18.04.4 LTS from Ubuntu releases.
2. Using a browser, connect to the IPMI of the H615c node and launch Remote Control.
3. Map the Ubuntu ISO using the Virtual Media Wizard and start the installation.
4. Select one of the two physical interfaces as the Primary network interface when prompted.
   An IP from a DHCP source is allocated when available, or you can switch to a manual IP configuration later. The network configuration is modified to a bond-based setup after the OS has been installed.
5. Provide a hostname followed by a domain name.
6. Create a user and provide a password.
7. Partition the disks according to your requirements.
8. Under Software Selection, select OpenSSH server and click Continue.
9. Reboot the node.

Configure Networking for Data and Management Access

The two physical network interfaces of the Kubernetes worker nodes are set up as a bond and VLAN interfaces for management and application, and NFS data traffic is created on top of it.

The inferencing applications and associated containers use the application network for connectivity.

1. Connect to the console of the Ubuntu instance as a user with root privileges and launch a terminal session.
2. Navigate to /etc/netplan and open the 01-netcfg.yaml file.
3. Update the netplan file based on the network details for the management, application, and NFS traffic in your environment.

The following template of the netplan file was used in this solution:

```
# This file describes the network interfaces available on your system
# For more information, see netplan(5).
network:
  version: 2
  renderer: networkd
  ethernets:
    enp59s0f0: #Physical Interface 1
      match:
        macaddress: <<mac_address Physical Interface 1>>
      set-name: enp59s0f0
```
mtu: 9000

enp59s0f1: # Physical Interface 2
match:
  macaddress: <<mac_address Physical Interface 2>>
set-name: enp59s0f1
mtu: 9000

bonds:
bond0:
  mtu: 9000
dhcp4: false
dhcp6: false
interfaces: [ enp59s0f0, enp59s0f1 ]
parameters:
  mode: 802.3ad
  mii-monitor-interval: 100

vlans:
vlan.3488: #Management VLAN
  id: 3488
  xref:{relative_path}bond0
dhcp4: false
addresses: [ipv4_address/subnet]
routes:
  - to: 0.0.0.0/0
    via: 172.21.232.111
    metric: 100
    table: 3488
  - to: x.x.x.x/x # Additional routes if any
    via: y.y.y.y
    metric: <<metric>>
    table: <<table #>>
routing-policy:
  - from: 0.0.0.0/0
    priority: 32768#Higher Priority than table 3487
    table: 3488

nameservers:
  addresses: [nameserver_ip]
  search: [ search_domain ]
mtu: 1500

vlan.3487:
  id: 3487
  xref:{relative_path}bond0
dhcp4: false
addresses: [ipv4_address/subnet]
routes:
  - to: 0.0.0.0/0
    via: 172.21.231.111
metric: 101
table: 3487
- to: x.x.x.x/x
  via: y.y.y.y
  metric: <<metric>>
  table: <<table #>>
routing-policy:
- from: 0.0.0.0/0
  priority: 32769#Lower Priority
  table: 3487
nameservers:
  addresses: [nameserver_ip]
  search: [ search_domain ]
mtu: 1500   vlan.3491:
id: 3491
xref:{relative_path}bond0
dhcp4: false
addresses: [ipv4_address/subnet]
mtu: 9000

4. Confirm that the priorities for the routing policies are lower than the priorities for the main and default tables.

5. Apply the netplan.

   sudo netplan --debug apply

6. Make sure that there are no errors.

7. If Network Manager is running, stop and disable it.

   systemctl stop NetworkManager
   systemctl disable NetworkManager

8. Add a host record for the server in DNS.

9. Open a VI editor to /etc/iproute2/rt_tables and add the two entries.
10. Match the table number to what you used in the netplan.

11. Open a VI editor to `/etc/sysctl.conf` and set the value of the following parameters.

   ```
   net.ipv4.conf.default.rp_filter=0
   net.ipv4.conf.all.rp_filter=0
   net.ipv4.ip_forward=1
   ```

12. Update the system.

   ```
   sudo apt-get update && sudo apt-get upgrade
   ```

13. Reboot the system

14. Repeat steps 1 through 13 for the other Ubuntu instance.

Next: Set Up the Deployment Jump and the Kubernetes Master Node VMs (Manual Deployment)

**Set Up the Deployment Jump VM and the Kubernetes Master Node VMs (Manual Deployment)**

A Deployment Jump VM running a Linux distribution is used for the following purposes:

- Deploying ONTAP Select using an Ansible playbook
- Deploying the Kubernetes infrastructure with NVIDIA DeepOps and GPU Operator
- Installing and configuring NetApp Trident

Three more VMs running Linux are set up; these VMs are configured as Kubernetes Master Nodes in this solution.

Ubuntu 18.04.4 LTS was used in this solution deployment.

1. Deploy the Ubuntu 18.04.4 LTS VM with VMware tools
You can refer to the high-level steps described in section Install Ubuntu 18.04.4 LTS.

2. Configure the in-band management network for the VM. See the following sample netplan template:

```yaml
# This file describes the network interfaces available on your system
# For more information, see netplan(5).
network:
  version: 2
  renderer: networkd
  ethernets:
    ens160:
      dhcp4: false
      addresses: [ipv4_address/subnet]
      routes:
        - to: 0.0.0.0/0
          via: 172.21.232.111
          metric: 100
          table: 3488
      routing-policy:
        - from: 0.0.0.0/0
          priority: 32768
          table: 3488
      nameservers:
        addresses: [nameserver_ip]
        search: [ search_domain ]
      mtu: 1500
```

This template is not the only way to setup the network. You can use any other approach that you prefer.

3. Apply the netplan.

```bash
sudo netplan --debug apply
```

4. Stop and disable Network Manager if it is running.

```bash
systemctl stop NetworkManager
systemctl disable NetworkManager
```

5. Open a VI editor to /etc/iproute2/rt_tables and add a table entry.
6. Add a host record for the VM in DNS.
7. Verify outbound internet access.
8. Update the system.

```
sudo apt-get update && sudo apt-get upgrade
```

9. Reboot the system.
10. Repeat steps 1 through 9 to set up the other three VMs.

Next: Deploy a Kubernetes Cluster with NVIDIA DeepOps (Automated Deployment)

**Deploy a Kubernetes Cluster with NVIDIA DeepOps Automated Deployment**

To deploy and configure the Kubernetes Cluster with NVIDIA DeepOps, complete the following steps:

1. Make sure that the same user account is present on all the Kubernetes master and worker nodes.
2. Clone the DeepOps repository.

```
git clone https://github.com/NVIDIA/deepops.git
```

3. Check out a recent release tag.

```
cd deepops
git checkout tags/20.08
```

If this step is skipped, the latest development code is used, not an official release.

4. Prepare the Deployment Jump by installing the necessary prerequisites.
5. Create and edit the Ansible inventory by opening a VI editor to `deepops/config/inventory`.
   a. List all the master and worker nodes under [all].
   b. List all the master nodes under [kube-master]
   c. List all the master nodes under [etcd]
   d. List all the worker nodes under [kube-node]

6. Enable GPUOperator by opening a VI editor to `deepops/config/group_vars/k8s-cluster.yml`. 
7. Set the value of `deepops_gpu_operator_enabled` to `true`.

8. Verify the permissions and network configuration.

    ```bash
    ansible all -m raw -a "hostname" -k -K
    ```

    - If SSH to the remote hosts requires a password, use `-k`.
    - If sudo on the remote hosts requires a password, use `-K`.

9. If the previous step passed without any issues, proceed with the setup of Kubernetes.

    ```bash
    ansible-playbook --limit k8s-cluster playbooks/k8s-cluster.yml -k -K
    ```

10. To verify the status of the Kubernetes nodes and the pods, run the following commands:

    ```bash
    kubectl get nodes
    ```

    ```bash
    kubectl get pods -A
    ```

    It can take a few minutes for all the pods to run.
11. Verify that the Kubernetes setup can access and use the GPUs.

```
./scripts/k8s_verify_gpu.sh
```

Expected sample output:

```
rarvind@deployment-jump:~/deepops$ ./scripts/k8s_verify_gpu.sh
job_name=cluster-gpu-tests
Node found with 3 GPUs
Node found with 3 GPUs
total_gpus=6
Creating/Deleting sandbox Namespace
updating test yml
downloading containers ...
```
job.batch/cluster-gpu-tests condition met
executing ...

12. Install Helm on the Deployment Jump.

./scripts/install_helm.sh

13. Remove the taints on the master nodes.

kubectl taint nodes --all node-role.kubernetes.io/master-

This step is required to run the LoadBalancer pods.

15. Edit the `config/helm/metallb.yml` file and provide a range of IP addresses in the Application Network to be used as LoadBalancer.

```yaml
---
# Default address range matches private network for the virtual cluster
# defined in virtual/.
# You should set this address range based on your site's infrastructure.
configInline:
  address-pools:
  - name: default
    protocol: layer2
    addresses:
      - 172.21.231.130-172.21.231.140#Application Network

controller:
  nodeSelector:
    node-role.kubernetes.io/master: ""
```

16. Run a script to deploy LoadBalancer.

./scripts/k8s_deploy_loadbalancer.sh
17. Deploy an Ingress Controller.

```bash
./scripts/k8s_deploy_ingress.sh
```

Next: Deploy and Configure ONTAP Select in the VMware Virtual Infrastructure (Automated Deployment)

**Deploy and Configure ONTAP Select in the VMware Virtual Infrastructure (Automated Deployment)**

To deploy and configure an ONTAP Select instance within the VMware Virtual Infrastructure, complete the following steps:

1. From the Deployment Jump VM, login to the NetApp Support Site and download the ONTAP Select OVA for ESXi.
2. Create a directory OTS and obtain the Ansible roles for deploying ONTAP Select.

```bash
mkdir OTS
cd OTS
git clone https://github.com/NetApp/ansible.git
cd ansible
```

3. Install the prerequisite libraries.
pip install requests
pip install pyvmomi

Open a VI Editor and create a playbook `ots_setup.yaml` with the below content to deploy the ONTAP Select OVA and initialize the ONTAP cluster.

---
- name: Create ONTAP Select Deploy VM from OVA (ESXi)
  hosts: localhost
  gather_facts: false
  connection: 'local'
  vars_files:
    - ots_deploy_vars.yaml
  roles:
    - na_ots_deploy
- name: Wait for 1 minute before starting cluster setup
  hosts: localhost
  gather_facts: false
  tasks:
  - pause:
    minutes: 1
- name: Create ONTAP Select cluster (ESXi)
  hosts: localhost
  gather_facts: false
  vars_files:
    - ots_cluster_vars.yaml
  roles:
    - na_ots_cluster

4. Open a VI editor, create a variable file `ots_deploy_vars.yaml`, and fill in the following parameters:
target_vcenter_or_esxi_host: "10.xxx.xx.xx"  # vCenter IP
host_login: "yourlogin@yourlab.local"  # vCenter Username
ovf_path: "'/run/deploy/ovapath/ONTAPdeploy.ova'"  # Path to OVA on Deployment Jump VM
datacenter_name: "your-Lab"  # Datacenter name in vCenter
esx_cluster_name: "your Cluster"  # Cluster name in vCenter
datastore_name: "your-select-dt"  # Datastore name in vCenter
mgt_network: "your-mgmt-network"  # Management Network to be used by OVA
deploy_name: "test-deploy-vm"  # Name of the ONTAP Select VM
deploy_ipAddress: "10.xxx.xx.xx"  # Management IP Address of ONTAP Select VM
deploy_gateway: "10.xxx.xx.1"  # Default Gateway
deploy_proxy_url: ""  # Proxy URL (Optional and if used)
deploy_netMask: "255.255.255.0"  # Netmask
deploy_product_company: "NetApp"  # Name of Organization
deploy_primaryDNS: "10.xxx.xx.xx"  # Primary DNS IP
deploy_secondaryDNS: ""  # Secondary DNS (Optional)
deploy_searchDomains: "your.search.domain.com"  # Search Domain Name

Update the variables to match your environment.

5. Open a VI editor, create a variable file `ots_cluster_vars.yaml`, and fill it out with the following parameters:
node_count: 1#Number of nodes in the ONTAP Cluster
monitor_job: truemonitor_deploy_job: true
deploy_api_url: #Use the IP of the ONTAP Select VM
deploy_login: "admin"
vcenter_login: "administrator@vsphere.local"
vcenter_name: "172.21.232.100"
esxi_hosts:
  - host_name: 172.21.232.102
  - host_name: 172.21.232.103
cluster_name: "HCI-ai-ots"# Name of ONTAP Cluster
cluster_ip: "172.21.232.118"# Cluster Management IP
cluster_netmask: "255.255.255.0"
cluster_gateway: "172.21.232.1"
cluster_ontap_image: "9.7"
cluster_ntp:
  - "10.61.186.231"
cluster_dns_ips:
  - "10.61.186.231"
cluster_dns_domains:
  - "sddc.netapp.com"
mgt_network: "NetApp HCI VDS 01-Management_Network"# Name of VM Port Group for Mgmt Network
data_network: "NetApp HCI VDS 01-NFS_Network"# Name of VM Port Group for NFS Network
internal_network: ""# Not needed for Single Node Cluster
instance_type: "small"
cluster_nodes:
  - node_name: "{{ cluster_name }}-01"
    ipAddress: 172.21.232.119# Node Management IP
    storage_pool: NetApp-HCI-Datastore-02 # Name of Datastore in vCenter to use
capacityTB: 1# Usable capacity will be ~700GB
    host_name: 172.21.232.102# IP Address of an ESXi host to deploy node

Update the variables to match your environment.

```
ansible-playbook ots_setup.yaml --extra-vars deploy_pwd=$'"P@ssw0rd"'
--extra-vars vcenter_password=$'"P@ssw0rd"' --extra-vars
ontap_pwd=$'"P@ssw0rd"' --extra-vars host_esx_password=$'"P@ssw0rd"'
--extra-vars host_password=$'"P@ssw0rd"' --extra-vars
deploy_password=$'"P@ssw0rd"'
```
7. Update the command with deploy_pwd `(ONTAP Select VM instance),
    `vcenter_password(vCenter), ontap_pwd (ONTAP login password), host_esx_password (VMware
    ESXi), host_password (vCenter), and deploy_password (ONTAP Select VM instance).

Configure the ONTAP Select Cluster – Manual Deployment

To configure the ONTAP Select cluster, complete the following steps:

1. Open a browser and log into the ONTAP cluster's System Manager using its cluster management IP.
2. On the DASHBOARD page, click Prepare Storage under Capacity.
3. Select the radio button to continue without onboard key manager, and click Prepare Storage.
4. On the NETWORK page, click the + sign in the Broadcast Domains window.
5. Enter the Name as NFS, set the MTU to 9000, and select the port e0b. Click Save.
Add Broadcast Domain

Specify the following details to add a new broadcast domain.

**NAME**
- NFS

**MTU**
- 9000

**ASSIGN PORTS**

<table>
<thead>
<tr>
<th>Port Name</th>
<th>hci-ai-ots-01</th>
</tr>
</thead>
<tbody>
<tr>
<td>e0b</td>
<td>✔️</td>
</tr>
<tr>
<td>e0c</td>
<td></td>
</tr>
</tbody>
</table>

**Network**

No protocols are enabled. To begin serving data to clients, enable the required protocols and assign the protocol addresses.

7. Enter a name for the SVM, select Enable NFS, provide an IP and subnet mask for the NFS LIF, set the Broadcast Domain to NFS, and click Save.

8. Click STORAGE in the left pane, and from the dropdown select Storage VMs
   a. Edit the SVM.
b. Select the checkbox under Resource Allocation, make sure that the local tier is listed, and click Save.
9. Click the SVM name, and on the right panel scroll down to Policies.

10. Click the arrow within the Export Policies tile, and click the default policy.

11. If there is a rule already defined, you can edit it; if no rule exists, then create a new one.
   a. Select NFS Network Clients as the Client Specification.
   b. Select the Read-Only and Read/Write checkboxes.
   c. Select the checkbox to Allow Superuser Access.
NetApp Trident is deployed by using an Ansible playbook that is available with NVIDIA DeepOps. Follow these steps to set up NetApp Trident:

1. From the Deployment Jump VM, navigate to the DeepOps directory and open a VI editor to `config/group_vars/netapp-trident.yml`. The file from DeepOps lists two backends and two storage classes. In this solution only one backend and storage class are used.

   Use the following template to update the file and its parameters (highlighted in yellow) to match your environment.
# vars file for netapp-trident playbook
# URL of the Trident installer package that you wish to download and use
trident_version: "20.07.0"  # Version of Trident desired
# Kubernetes version
# Note: Do not include patch version, e.g. provide value of 1.16, not 1.16.7.
# Note: Versions 1.14 and above are supported when deploying Trident with DeepOps.
#   If you are using an earlier version, you must deploy Trident manually.
k8s_version: 1.17.9  # Version of Kubernetes running
# Denotes whether or not to create new backends after deploying trident
# For more info, refer to: https://netapp-trident.readthedocs.io/en/stable-v20.04/kubernetes/operator-install.html#creating-a-trident-backend
create_backends: true
# List of backends to create
# For more info on parameter values, refer to: https://netapp-trident.readthedocs.io/en/stable-v20.04/kubernetes/operations/tasks/backends/ontap.html
# Note: Parameters other than those listed below are not available when creating a backend via DeepOps
#   If you wish to use other parameter values, you must create your backend manually.
backends_to_create:
  - backendName: ontap-flexvol
    storageDriverName: ontap-nas  # only 'ontap-nas' and 'ontap-nas-flexgroup' are supported when creating a backend via DeepOps
    managementLIF: 172.21.232.118  # Cluster Management IP or SVM Mgmt LIF
    dataLIF: 172.21.235.119  # NFS LIF IP
    svm: infra-NFS-hci-ai#  # Name of SVM
    username: admin#  # Username to connect to the ONTAP cluster
    password: P@ssw0rd##  # Password to login
    storagePrefix: trident
    limitAggregateUsage: ""
    limitVolumeSize: ""
    nfsMountOptions: ""
    defaults:
      spaceReserve: none
      snapshotPolicy: none
      snapshotReserve: 0
# Add additional backends as needed
# Denotes whether or not to create new StorageClasses for your NetApp storage
# For more info, refer to: https://netapp-trident.readthedocs.io/en/stable-v20.04/kubernetes/operator-install.html#creating-a-storage-class
create_StorageClasses: true
# List of StorageClasses to create
# Note: Each item in the list should be an actual K8s StorageClass definition in yaml format
storageClasses_to_create:
  - apiVersion: storage.k8s.io/v1
    kind: StorageClass
    metadata:
      name: ontap-flexvol
      annotations:
        storageclass.kubernetes.io/is-default-class: "true"
    provisioner: csi.trident.netapp.io
    parameters:
      backendType: "ontap-nas"
# Add additional StorageClasses as needed
# Denotes whether or not to copy tridentctl binary to localhost
copy_tridentctl_to_localhost: true
# Directory that tridentctl will be copied to on localhost
tridentctl_copy_to_directory: ../ # will be copied to 'deepops/' directory

2. Setup NetApp Trident by using the Ansible playbook.
   ```bash
   ansible-playbook -l k8s-cluster playbooks/netapp-trident.yml
   ```

3. Verify that Trident is running.
   ```bash
   ./tridentctl -n trident version
   ```
The expected output is as follows:

```
larvind@deployment-jump:~/deepops$ ./tridentctl -n trident version
+----------------+----------------+
<table>
<thead>
<tr>
<th>SERVER VERSION</th>
<th>CLIENT VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>20.07.0</td>
<td>20.07.0</td>
</tr>
</tbody>
</table>
+----------------+----------------+
```

Next: Deploy NVIDIA Triton Inference Server (Automated Deployment)

**Deploy NVIDIA Triton Inference Server (Automated Deployment)**

To set up automated deployment for the Triton Inference Server, complete the following steps:

1. Open a VI editor and create a PVC yaml file `vi pvc-triton-model-repo.yaml`.

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: triton-pvc namespace: triton
   spec:
     accessModes:
       - ReadWriteMany
     resources:
       requests:
         storage: 10Gi
     storageClassName: ontap-flexvol
   ```

2. Create the PVC.

   ```bash
   kubectl create -f pvc-triton-model-repo.yaml
   ```

3. Open a VI editor, create a deployment for the Triton Inference Server, and call the file `triton_deployment.yaml`.

   ```yaml
   ---
   apiVersion: v1
   kind: Service
   metadata:
     labels:
       app: triton-3gpu
     name: triton-3gpu
   ```
namespace: triton
spec:
  ports:
  - name: grpc-trtis-serving
    port: 8001
    targetPort: 8001
  - name: http-trtis-serving
    port: 8000
    targetPort: 8000
  - name: prometheus-metrics
    port: 8002
    targetPort: 8002
selector:
  app: triton-3gpu
  type: LoadBalancer
---

apiVersion: v1
kind: Service
metadata:
  labels:
  - app: triton-1gpu
  name: triton-1gpu
namespace: triton
spec:
  ports:
  - name: grpc-trtis-serving
    port: 8001
    targetPort: 8001
  - name: http-trtis-serving
    port: 8000
    targetPort: 8000
  - name: prometheus-metrics
    port: 8002
    targetPort: 8002
selector:
  app: triton-1gpu
  type: LoadBalancer
---

apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
  - app: triton-3gpu
  name: triton-3gpu
namespace: triton
spec:
replicas: 1
selector:
  matchLabels:
    app: triton-3gpu    version: v1
template:
  metadata:
    labels:
      app: triton-3gpu
      version: v1
  spec:
    containers:
    - image: nvcr.io/nvidia/tritonserver:20.07-v1-py3
      command: ["/bin/sh", ":-c"]
      args: ["trtserver --model-store=/mnt/model-repo"]
      imagePullPolicy: IfNotPresent
      name: triton-3gpu
      ports:
        - containerPort: 8000
        - containerPort: 8001
        - containerPort: 8002
      resources:
        limits:
          cpu: "2"
          memory: 4Gi
          nvidia.com/gpu: 3
        requests:
          cpu: "2"
          memory: 4Gi
          nvidia.com/gpu: 3
      volumeMounts:
        - name: triton-model-repo
          mountPath: /mnt/model-repo
          nodeSelector:
            gpu-count: "3"
      volumes:
        - name: triton-model-repo
          persistentVolumeClaim:
            claimName: triton-pvc---

apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
    app: triton-1gpu
    name: triton-1gpu
    namespace: triton
spec:
  replicas: 3
Two deployments are created here as an example. The first deployment spins up a pod that uses three GPUs and has replicas set to 1. The other deployment spins up three pods each using one GPU while the replica is set to 3. Depending on your requirements, you can change the GPU allocation and replica counts.

Both of the deployments use the PVC created earlier and this persistent storage is provided to the Triton inference servers as the model repository.

For each deployment, a service of type LoadBalancer is created. The Triton Inference Server can be
accessed by using the LoadBalancer IP which is in the application network.

A nodeSelector is used to ensure that both deployments get the required number of GPUs without any issues.

4. Label the K8 worker nodes.

```bash
kubectl label nodes hci-ai-k8-worker-01 gpu-count=3
kubectl label nodes hci-ai-k8-worker-02 gpu-count=1
```

5. Create the deployment.

```bash
kubectl apply -f triton_deployment.yaml
```

6. Make a note of the LoadBalancer service external LPS.

```bash
kubectl get services -n triton
```

The expected sample output is as follows:

```
NAME            TYPE              CLUSTER-IP       EXTERNAL-IP          PORT(S)    AGE
```

7. Connect to any one of the pods that were created from the deployment.

```bash
kubectl exec -n triton --stdin --tty triton-1gpu-86c4c8dd64-5451x -- /bin/bash
```

8. Set up the model repository by using the example model repository.

```bash
git clone
cd triton-inference-server
git checkout r20.07
```

9. Fetch any missing model definition files.

```bash
cd docs/examples
./fetch_models.sh
```

10. Copy all the models to the model repository location or just a specific model that you wish to use.
In this solution, only the resnet50_netdef model is copied over to the model repository as an example.

11. Check the status of the Triton Inference Server.

```bash
curl -v <<LoadBalancer_IP_recorded_earlier>>:8000/api/status
```

The expected sample output is as follows:

```bash
curl -v 172.21.231.132:8000/api/status
*   Trying 172.21.231.132...
* TCP_NODELAY set
* Connected to 172.21.231.132 (172.21.231.132) port 8000 (#0)
> GET /api/status HTTP/1.1
> Host: 172.21.231.132:8000
> User-Agent: curl/7.58.0
> Accept: */*
>

        data_type: TYPE_FP32
        format: FORMAT_NCHW
        dims: 3
    
```
Next: Deploy the Client for Triton Inference Server (Automated Deployment)

Deploy the Client for Triton Inference Server (Automated Deployment)

To deploy the client for the Triton Inference Server, complete the following steps:
1. Open a VI editor, create a deployment for the Triton client, and call the file `triton_client.yaml`.

```yaml
---
apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
    app: triton-client
    name: triton-client
    namespace: triton
spec:
  replicas: 1
  selector:
    matchLabels:
      app: triton-client
      version: v1
  template:
    metadata:
      labels:
        app: triton-client
        version: v1
    spec:
      containers:
      - image: nvcr.io/nvidia/tritonserver:20.07-v1-py3-clientsdk
        imagePullPolicy: IfNotPresent
        name: triton-client
        resources:
          limits:
            cpu: "2"
            memory: 4Gi
          requests:
            cpu: "2"
            memory: 4Gi
```

2. Deploy the client.

```bash
kubectl apply -f triton_client.yaml
```

Next: Collect Inference Metrics from Triton Inference Server

**Collect Inference Metrics from Triton Inference Server**

The Triton Inference Server provides Prometheus metrics indicating GPU and request statistics.
By default, these metrics are available at 
http://[triton_inference_server_IP]:8002/metrics.

The Triton Inference Server IP is the LoadBalancer IP that was recorded earlier.

The metrics are only available by accessing the endpoint and are not pushed or published to any remote server.
Validation Results

To run a sample inference request, complete the following steps:

1. Get a shell to the client container/pod.

   ```bash
   kubectl exec --stdin --tty <<client_pod_name>> -- /bin/bash
   ```

2. Run a sample inference request.

   ```bash
   image_client -m resnet50_netdef -s INCEPTION -u
   <<LoadBalancer_IP_recorded earlier>>:8000 -c 3 images/mug.jpg
   ```

This inferencing request calls the `resnet50_netdef` model that is used for image recognition. Other clients can also send inferencing requests concurrently by following a similar approach and calling out the appropriate model.
