 - Restore key-manager configuration on the upgraded node1 9
 - Move non-root aggregates and NAS data LIFs owned by node1 from node2 to the upgraded node1 9

Stage 3. Boot node1 with the AFF A900 or FAS9500 controller and NVRAM modules

Boot node1 with the AFF A900 or FAS9500 controller and NVRAM modules

Node1 with the AFF A900 or FAS9500 controller and NVRAM modules is now ready for boot up. An AFF A700 to AFF A900 or a FAS9000 to FAS9500 upgrade by swapping the controller and NVRAM modules involves moving only the console and management connections. This section provides the steps required to boot node1 with the AFF A900 or FAS9500 controller and NVRAM modules.

Steps

1. If NetApp Storage Encryption (NSE) is in use on this configuration, the `setenv bootarg.storageencryption.support` command must be set to `true`, and the `kmip.init.maxwait` variable must be set to `off` to avoid a boot loop after the node1 configuration is loaded:

```
setenv bootarg.storageencryption.support true
```

```
setenv kmip.init.maxwait off
```

2. Boot the node into the boot menu:

```
boot_ontap menu
```

3. Reassign the AFF A700 node1 disks to AFF A900 node1 by entering "22/7" and selecting the hidden option `boot_after_controller_replacement` when the node stops at the boot menu.

After a short delay, you are prompted to enter the name of the node that is being replaced. If there are shared disks (also called Advanced Disk Partitioning (ADP) or partitioned disks), you are prompted to enter the node name of the HA partner.

These prompts might get buried in the console messages. If you do not enter a node name or enter an incorrect name, you are prompted to enter the name again.

If `[localhost:disk.encryptNoSupport:ALERT]: Detected FIPS-certified encrypting drive and, or, [localhost:diskown.errorDuringIO:error]: error 3 (disk failed) on disk errors occur, perform the following steps:`

1. Halt the node at the LOADER prompt.
2. Check and reset the storage encryption bootargs mentioned in [Step 1](#).
3. At the loader prompt, boot up:

```
boot_ontap
```

You can use the following example as a reference:

Expand the console output example

```
LOADER-A> boot_ontap menu

(wipeconfig)                               Clean all configuration on boot
```

```

device
  (boot_after_controller_replacement) Boot after controller upgrade
  (boot_after_mcc_transition)         Boot after MCC transition
  (9a)                                Unpartition all disks and remove
their ownership information.
  (9b)                                Clean configuration and
initialize node with partitioned disks.
  (9c)                                Clean configuration and
initialize node with whole disks.
  (9d)                                Reboot the node.
  (9e)                                Return to main boot menu.

```

The boot device has changed. System configuration information could be lost. Use option (6) to restore the system configuration, or option (4) to initialize all disks and setup a new system. Normal Boot is prohibited.

Please choose one of the following:

- (1) Normal Boot.
 - (2) Boot without /etc/rc.
 - (3) Change password.
 - (4) Clean configuration and initialize all disks.
 - (5) Maintenance mode boot.
 - (6) Update flash from backup config.
 - (7) Install new software first.
 - (8) Reboot node.
 - (9) Configure Advanced Drive Partitioning.
 - (10) Set Onboard Key Manager recovery secrets.
 - (11) Configure node for external key management.
- Selection (1-11)? boot_after_controller_replacement

This will replace all flash-based configuration with the last backup to disks. Are you sure you want to continue?: yes

WARNING: System ID mismatch. This usually occurs when replacing a
boot device or NVRAM cards!
Override system ID? {y|n} y
.
.
.
.
Login:
```

The system IDs shown in the preceding example are example IDs. The actual system IDs of the nodes that you are upgrading will be different.

Between entering node names at the prompt and the login prompt, the node reboots a few times to restore the environment variables, update firmware on the cards in the system, and for other ONTAP updates.

Verify the node1 installation

You must verify the node1 installation with the AFF A900 or FAS9500 controller and NVRAM modules. Because there is no change to physical ports, you are not required to map the physical ports from the old node1 to the replacement node1.

About this task

After you boot node1 with the AFF A900 or FAS9500 controller module, you must verify that it is installed correctly. You must wait for node1 to join quorum and then resume the controller replacement operation.

At this point in the procedure, the controller upgrade operation should have paused as node1 attempts to join quorum automatically.

Steps

1. Verify that node1 has joined quorum:

```
cluster show -node node1 -fields health
```

The output of the `health` field should be `true`.

2. Verify that node1 is part of the same cluster as node2 and that it is healthy:

```
cluster show
```

3. Switch to advanced privilege mode:

```
set advanced
```

4. Check the status of the controller replacement operation and verify that it is in a paused state and in the same state that it was in before node1 was halted to perform the physical tasks of installing new controllers and moving cables:

```
system controller replace show
```

```
system controller replace show-details
```

5. Resume the controller replacement operation:

```
system controller replace resume
```

6. The controller replacement operation pauses for intervention with the following message:

```

Cluster::*> system controller replace show
Node           Status           Error-Action
-----
Node1          Paused-for-intervention  Follow the instructions given
in
Node2          None              Step Details

```

Step Details:

To complete the Network Reachability task, the ONTAP network configuration must be manually adjusted to match the new physical network configuration of the hardware. This includes:

1. Re-create the interface group, if needed, before restoring VLANs. For detailed commands and instructions, refer to the "Re-creating VLANs, ifgrps, and broadcast domains" section of the upgrade controller hardware guide for the ONTAP version running on the new controllers.
 2. Run the command "cluster controller-replacement network displaced-vlans show" to check if any VLAN is displaced.
 3. If any VLAN is displaced, run the command "cluster controller-replacement network displaced-vlans restore" to restore the VLAN on the desired port.
- 2 entries were displayed.

In this procedure, section *Re-creating VLANs, ifgrps, and broadcast domains* has been renamed *Restore network configuration on node1*.

7. With the controller replacement in a paused state, proceed to [Restore network configuration on node1](#).

Restore network configuration on node1

After you confirm that node1 is in quorum and can communicate with node2, verify that node1's VLANs, interface groups, and broadcast domains are seen on node1. Also, verify that all node1 network ports are configured in their correct broadcast domains.

About this task

For more information on creating and re-creating VLANs, interface groups, and broadcast domains, refer to [References](#) to link to the *Network Management* content.

Steps

1. List all the physical ports that are on upgraded node1:

```
network port show -node node1
```

All physical network ports, VLAN ports, and interface group ports on the node are displayed. From this output, you can see any physical ports that have been moved into the `Cluster` broadcast domain by ONTAP. You can use this output to aid in deciding which ports should be used as interface group member ports, VLAN base ports, or standalone physical ports for hosting LIFs.

2. List the broadcast domains on the cluster:

```
broadcast-domain show
```

3. List the network port reachability of all ports on node1:

```
network port reachability show -node node1
```

You should see output like the following example:

```
Cluster::> reachability show -node node1
(network port reachability show)
Node      Port      Expected Reachability      Reachability
Status
-----
Node1
    a0a      Default:Default      ok
    a0a-822  Default:822          ok
    a0a-823  Default:823          ok
    e0M      Default:Mgmt         ok
    e11a     -                    no-reachability
    e11b     -                    no-reachability
    e11c     -                    no-reachability
    e11d     -                    no-reachability
    e3a      -                    no-reachability
    e3b      -                    no-reachability
    e4a      Cluster:Cluster      ok
    e4e      Cluster:Cluster      ok
    e5a      -                    no-reachability
    e7a      -                    no-reachability
    e9a      Default:Default      ok
    e9a-822  Default:822          ok
    e9a-823  Default:823          ok
    e9b      Default:Default      ok
    e9b-822  Default:822          ok
    e9b-823  Default:823          ok
    e9c      Default:Default      ok
    e9d      Default:Default      ok
22 entries were displayed.
```

In the preceding example, node1 booted after the controller replacement. Some ports do not have reachability because there is no physical connectivity. You must repair any ports with a reachability status

other than `ok`.

During an AFF A700 to AFF A900 or a FAS9000 to FAS9500 controller upgrade, the network ports and their connectivity should not change. All ports should reside in the correct broadcast domains and the network port reachability should not change. However, before moving LIFs from node2 back to node1, you must verify the reachability and health status of the network ports.

4. Repair the reachability for each of the ports on node1 with a reachability status other than `ok` by using the following command, in the following order:

```
network port reachability repair -node node_name -port port_name
```

- a. Physical ports
- b. VLAN ports

You should see output like the following example:

```
Cluster ::> reachability repair -node node1 -port e11b
```

```
Warning: Repairing port "node1:e11b" may cause it to move into a  
different broadcast domain, which can cause LIFs to be re-homed away  
from the port. Are you sure you want to continue? {y|n}:
```

A warning message, as shown in the preceding example, is expected for ports with a reachability status that might be different from the reachability status of the broadcast domain where it is currently located. Review the connectivity of the port and answer `y` or `n` as appropriate.

Verify that all physical ports have their expected reachability:

```
network port reachability show
```

As the reachability repair is performed, ONTAP attempts to place the ports in the correct broadcast domains. However, if a port's reachability cannot be determined and does not belong to any of the existing broadcast domains, ONTAP will create new broadcast domains for these ports.

5. Verify port reachability:

```
network port reachability show
```

When all ports are correctly configured and added to the correct broadcast domains, the `network port reachability show` command should report the reachability status as `ok` for all connected ports, and the status as `no-reachability` for ports with no physical connectivity. If any port reports a status other than these two, perform the reachability repair and add or remove ports from their broadcast domains as instructed in [Step 4](#).

6. Verify that all ports have been placed into broadcast domains:

```
network port show
```

7. Verify that all ports in the broadcast domains have the correct maximum transmission unit (MTU) configured:

```
network port broadcast-domain show
```

8. Restore LIF home ports, specifying the Vserver and LIF home ports, if any, that need to be restored by using the following steps:
 - a. List any LIFs that are displaced:

```
displaced-interface show
```

- b. Restore LIF home nodes and home ports:

```
displaced-interface restore-home-node -node node_name -vserver vserver_name  
-lif-name LIF_name
```

9. Verify that all LIFs have a home port and are administratively up:

```
network interface show -fields home-port,status-admin
```

Restore key-manager configuration on the upgraded node1

If you are using NetApp Volume Encryption (NVE) to encrypt volumes on the system you are upgrading, the encryption configuration must be synchronized to the new nodes. If you do not restore key-manager, when you relocate the node1 aggregates from node2 to the upgraded node1 by using ARL, encrypted volumes will be taken offline.

About this task

Synchronize the encryption configuration to the new nodes by performing the following steps:

Steps

1. Synchronize the encryption configuration for Onboard Key Manager (OKM) by using the following command at the cluster prompt:

```
security key-manager onboard sync
```

2. Enter the cluster-wide passphrase for the OKM.

Move non-root aggregates and NAS data LIFs owned by node1 from node2 to the upgraded node1

After you verify network configuration on node1 and before you relocate aggregates from node2 to node1, you must verify that the NAS data LIFs belonging to node1 that are currently on node2 are relocated from node2 to node1. You must also verify that the SAN LIFs exist on node1.

About this task

Remote LIFs handle traffic to SAN LUNs during the upgrade procedure. Moving SAN LIFs is not necessary for cluster or service health during the upgrade. SAN LIFs are not moved unless they need to be mapped to new

ports. After you bring node1 online, you must verify that the LIFs are healthy and located on the appropriate ports.

Steps

1. Resume the relocation operation:

```
system controller replace resume
```

The system performs the following tasks:

- Cluster quorum check
- System ID check
- Image version check
- Target platform check
- Network reachability check

The operation pauses at this stage in the network reachability check.

2. Perform a network reachability check:

```
network port reachability -show-detail -node node1
```

Confirm that all connected ports, including the interface group and VLAN ports, show their status as OK.

3. Resume the relocation operation:

```
system controller replace resume
```

The system performs the following checks:

- Cluster health check
- Cluster LIF status check

After performing these checks, the system relocates the non-root aggregates and NAS data LIFs owned by node1 to the new node1.

The controller replacement operation pauses after the resource relocation is complete.

4. Check the status of the aggregate relocation and NAS data LIF move operations:

```
system controller replace show-details
```

If the controller replacement procedure is paused, check and correct the error, if any, and then issue `resume` to continue the operation.

5. If necessary, restore and revert any displaced LIFs. List any displaced LIFs:

```
cluster controller-replacement network displaced-interface show
```

If any LIFs are displaced, restore the home node back to node1:

```
cluster controller-replacement network displaced-interface restore-home-node
```

6. Resume the operation to prompt the system to perform the required post-checks:

```
system controller replace resume
```

The system performs the following post-checks:

- Cluster quorum check
- Cluster health check
- Aggregates reconstruction check
- Aggregate status check
- Disk status check
- Cluster LIF status check
- Volume check
