Administrator accounts created prior to ONTAP 9.0 continue to use MD5 passwords after the upgrade, until the passwords are manually changed. MD5 is less secure than SHA-2. Therefore, after upgrading, you should prompt users of MD5 accounts to change their passwords to use the default SHA-512 hash function.

About this task

The password hash functionality enables you to do the following:

- Display user accounts that match the specified hash function.
- Expire accounts that use a specified hash function (for example, MD5), forcing the users to change their passwords in their next login.
- Lock accounts whose passwords use the specified hash function.
- When reverting to a release earlier than ONTAP 9, reset the cluster administrator's own password for it to be compatible with the hash function (MD5) that is supported by the earlier release.

ONTAP accepts pre-hashed SHA-2 passwords only by using NetApp Manageability SDK (`security-login-create` and `security-login-modify-password`).

Steps

1. Migrate the MD5 administrator accounts to the SHA-512 password hash function:
   a. Expire all MD5 administrator accounts: `security login expire-password -vserver * -username * -hash-function md5`

      Doing so forces MD5 account users to change their passwords upon next login.

   b. Ask users of MD5 accounts to log in through a console or SSH session.

      The system detects that the accounts are expired and prompts users to change their passwords. SHA-512 is used by default for the changed passwords.

2. For MD5 accounts whose users do not log in to change their passwords within a period of time, force the account migration:
   a. Lock accounts that still use the MD5 hash function (advanced privilege level): `security login expire-password -vserver * -username * -hash-function md5 -lock-after integer`

      After the number of days specified by `-lock-after`, users cannot access their MD5 accounts.

   b. Unlock the accounts when the users are ready to change their passwords: `security login unlock -vserver svm_name -username user_name`
   c. Have users log in to their accounts through a console or SSH session and change their passwords when the system prompts them to do so.

Diagnose and correct ONTAP file access issues with System Manager

Beginning with ONTAP 9.8, you can trace and view file access concerns.

Steps

1. In System Manager, select **Storage > Storage VMs**.
2. Select the storage VM on which you want to perform a trace.
3. Click ⋮ **More**.
4. Click **Trace File Access**.
5. Provide the user name and client IP address, then click **Start Tracing**.

   The trace results are displayed in a table. The **Reasons** column provides the reason why a file could not be accessed.

6. Click ⌄ in the left column of the results table to view the file access permissions.

Manage multi-admin verification

Learn about ONTAP multi-admin verification

Beginning with ONTAP 9.11.1, you can use multi-admin verification (MAV) to ensure that certain operations, such as deleting volumes or snapshots, can be executed only after approvals from designated administrators. This prevents compromised, malicious, or inexperienced administrators from making undesirable changes or deleting data.

Configuring multi-admin verification consists of:

- Creating one or more administrator approval groups.
- Enabling multi-admin verification functionality.
- Adding or modifying rules.

After initial configuration, these elements can be modified only by administrators in a MAV approval group (MAV administrators).

When multi-admin verification is enabled, the completion of every protected operation requires these steps:

1. When a user initiates the operation, a request is generated.
2. Before the operation can be executed, at least one MAV administrator must approve.
3. Upon approval, the user is prompted and completes the operation.

> ⓘ If you need to disable multi-admin verification functionality without MAV administrator approval, contact NetApp Support and mention the following Knowledge Base article: How to disable Multi-Admin Verification if MAV admin is unavailable.

Multi-admin verification is not intended for use with volumes or workflows that involve heavy automation, because each automated task would require approval before the operation could be completed. If you want to use automation and MAV together, it’s recommended that you use queries for specific MAV operations. For example, you could apply `volume delete` MAV rules only to volumes where automation is not involved, and you could designate those volumes with a particular naming scheme.

> Multi-admin verification is not available with Cloud Volumes ONTAP.

How multi-admin verification works

Multi-admin verification consists of:

- A group of one or more administrators with approval and veto powers.
- A set of protected operations or commands in a *rules table*.
- A *rules engine* to identify and control execution of protected operations.

MAV rules are evaluated after role-based access control (RBAC) rules. Therefore, administrators who execute or approve protected operations must already possess the minimum RBAC privileges for those operations. Learn more about RBAC.

System-defined rules

When multi-admin verification is enabled, system-defined rules (also known as *guard-rail* rules) establish a set of MAV operations to contain the risk of circumventing the MAV process itself. These operations cannot be removed from the rules table. Once MAV is enabled, operations designated by an asterisk (*) require approval by one or more administrators before execution, except for **show** commands.

- `security multi-admin-verify modify` operation *

  Controls the configuration of multi-admin verification functionality.

- `security multi-admin-verify approval-group` operations *

  Control membership in the set of administrators with multi-admin verification credentials.

- `security multi-admin-verify rule` operations *

  Control the set of commands requiring multi-admin verification.

- `security multi-admin-verify request` operations

  Control the approval process.

Rule-protected commands

In addition to system-defined operations, the following commands are protected by default when multi-admin verification is enabled, but you can modify the rules to remove protection for these commands:

- security login password
- security login unlock
- set

Each ONTAP version provides more commands you can choose to protect with multi-admin verification rules. Choose your ONTAP release for the full list of commands available for protection.

How multi-admin approval works

Any time a protected operation is entered on a MAV-protected cluster, an operation execution request is sent to the designated MAV administrator group.

You can configure:

- The names, contact information, and number of administrators in the MAV group.

  A MAV administrator should have an RBAC role with cluster administrator privileges.

- The number of MAV administrator groups.
  - A MAV group is assigned for each protected operation rule.
  - For multiple MAV groups, you can configure which MAV group approves a given rule.
- The number of MAV approvals required to execute a protected operation.
- An *approval expiry* period within which a MAV administrator must respond to an approval request.
- An *execution expiry* period within which the requesting administrator must complete the operation.

Once these parameters are configured, MAV approval is required to modify them.

MAV administrators cannot approve their own requests to execute protected operations. Therefore:

- MAV should not be enabled on clusters with only one administrator.
- If there is only one person in the MAV group, that MAV administrator cannot initiate protected operations; regular administrators must initiate protected operations, and the MAV administrator can only approve.
- If you want MAV administrators to be able to execute protected operations, the number of MAV administrators must be one greater than the number of approvals required.
  For example, if two approvals are required for a protected operation, and you want MAV administrators to execute them, there must be three people in the MAV administrators group.

MAV administrators can receive approval requests in email alerts (using EMS) or they can query the request queue. When they receive a request, they can take one of three actions:

- Approve
- Reject (veto)
- Ignore (no action)

Email notifications are sent to all approvers associated with a MAV rule when:

- A request is created.
- A request is approved or vetoed.
- An approved request is executed.

If the requestor is in the same approval group for the operation, they will receive an email when their request is approved.

> A requestor can’t approve their own requests even if they are in the approval group (although they can get email notifications for their own requests). Requestors who are not in approval groups (that is, who are not MAV administrators) don’t receive email notifications.

How protected operation execution works

If execution is approved for a protected operation, the requesting user continues with the operation when prompted. If the operation is vetoed, the requesting user must delete the request before proceeding.

MAV rules are evaluated after RBAC permissions. As a result, a user without sufficient RBAC permissions for operation execution cannot initiate the MAV request process.

MAV rules are evaluated before the protected operation is executed. This means that rules are enforced based on the current state of the system. For example, if a MAV rule is created for `volume modify` with a query of `-size 5GB`, using `volume modify` to resize a 5GB volume to 2GB will require MAV approval, but resizing a 2GB volume to 5GB will not.

Manage ONTAP administrator approval groups for MAV

Before enabling multi-admin verification (MAV), you must create an admin approval group containing one or more administrators to be granted approve or veto authority. Once you have enabled multi-admin verification, any modifications to approval group membership requires approval from one of the existing qualified administrators.

About this task

You can add existing administrators to a MAV group or create new administrators.

MAV functionality honors existing role-based access control (RBAC) settings. Potential MAV administrators must have sufficient privilege to execute protected operations before they are added to MAV administrator groups. Learn more about RBAC.

You can configure MAV to alert MAV administrators that approval requests are pending. To do so, you must configure email notifications—in particular, the `Mail From` and `Mail Server` parameters—or you can clear these parameters to disable notification. Without email alerts, MAV administrators must check the approval queue manually.

Beginning with ONTAP 9.15.1, you can configure Active Directory (AD) users as MAV administrators. The AD user must be configured as an ONTAP administrator.

System Manager procedure

If you want to create a MAV approval group for the first time, see the System Manager procedure to enable multi-admin verification.

To modify an existing approval group or create an additional approval group:

1. Identify administrators to receive multi-admin verification.
   a. Click **Cluster > Settings.**

b. Click → next to **Users and Roles.**

c. Click + Add under **Users.**

d. Modify the roster as needed.

   For more information, see Control administrator access.

2. Create or modify the MAV approval group:

   a. Click **Cluster > Settings.**

   b. Click → next to **Multi-Admin Approval** in the **Security** section.
   (You will see the ⚙ icon if MAV is not yet configured.)

      - Name: enter a group name.
      - Approvers: select approvers from a list of users.
      - Email address: enter email address(es).
      - Default group: select a group.

MAV approval is required to edit an existing configuration once MAV is enabled.

CLI procedure

1. Verify that values have been set for the `Mail From` and `Mail Server` parameters. Enter:

   `event config show`

   The display should be similar to the following:

```
cluster01::> event config show
                             Mail From:  admin@localhost
                           Mail Server:  localhost
                             Proxy URL:  -
                            Proxy User:  -
 Publish/Subscribe Messaging Enabled:  true
```

   To configure these parameters, enter:

   `event config modify -mail-from` *`email_address`* `-mail-server` *`server_name`*

   Learn more about `event config show` and `event config modify` in the ONTAP command reference.

2. Identify administrators to receive multi-admin verification

If you want to…	Enter this command
Display current administrators	`security login show`
Modify credentials of current administrators	`security login modify` *`<parameters>`*

If you want to…	Enter this command
Create new administrator accounts	`security login create -user-or-group -name admin_name -application ssh -authentication-method password`

Learn more about `security login show`, `security login modify`, and `security login create` in the ONTAP command reference.

3. Create the MAV approval group:

   `security multi-admin-verify approval-group create [ -vserver svm_name] -name group_name -approvers approver1[,approver2…] [[-email address1], address1…]`

   - `-vserver` - Only the admin SVM is supported in this release.
   - `-name` - The MAV group name, up to 64 characters.
   - `-approvers` - The list of one or more approvers. For AD users, use the format `domain\user`. For example, `mydomain\pavan`.
   - `-email` - One or more email addresses that are notified when a request is created, approved, vetoed, or executed.

     Example: The following command creates a MAV group with two members and associated email addresses.

     ```
     cluster-1::> security multi-admin-verify approval-group create -name
     mav-grp1 -approvers pavan,julia -email
     pavan@myfirm.com,julia@myfirm.com
     ```

4. Verify group creation and membership:

   `security multi-admin-verify approval-group show`

   Example:

   ```
   cluster-1::> security multi-admin-verify approval-group show
   Vserver  Name         Approvers        Email
   -------  ---------------- ------------------
   ------------------------------------------------------------
   svm-1    mav-grp1   pavan,julia      email
   pavan@myfirm.com,julia@myfirm.com
   ```

Use these commands to modify your initial MAV group configuration.

Note: All require MAV administrator approval before execution.

If you want to…	Enter this command
Modify the group characteristics or modify existing member information	`security multi-admin-verify approval-group modify [parameters]`
Add or remove members	`security multi-admin-verify approval-group replace [-vserver svm_name] -name group_name [-approvers-to-add approver1[,approver2…]][-approvers-to-remove approver1[,approver2…]]`
Delete a group	`security multi-admin-verify approval-group delete [-vserver svm_name] -name group_name`

Enable or disable multi-admin verification in ONTAP

Multi-admin verification (MAV) must be enabled explicitly. Once you have enabled multi-admin verification, approval by administrators in a MAV approval group (MAV administrators) is required to delete it.

About this task

Once MAV is enabled, modifying or disabling MAV requires MAV administrator approval.

> If you need to disable multi-admin verification functionality without MAV administrator approval, contact NetApp Support and mention the following Knowledge Base article: How to disable Multi-Admin Verification if MAV admin is unavailable.

When you enable MAV, you can specify the following parameters globally.

Approval groups

A list of global approval groups. At least one group is required to enable MAV functionality.

> If you are using MAV with Autonomous Ransomware Protection (ARP), define a new or existing approval group that is responsible for approving ARP pause, disable, and clear suspect requests.

Required approvers

The number of approvers required to execute a protected operation. The default and minimum number is 1.

> The required number of approvers must be less than the total number of unique approvers in the default approval groups.

Approval expiry (hours, minutes, seconds)

The period within which a MAV administrator must respond to an approval request. The default value is one hour (1h), the minimum supported value is one second (1s), and the maximum supported value is 14 days

(14d).

Execution expiry (hours, minutes, seconds)

The period within which the requesting administrator must complete the:: operation. The default value is one hour (1h), the minimum supported value is one second (1s), and the maximum supported value is 14 days (14d).

You can also override any of these parameters for specific operation rules.

System Manager procedure

1. Identify administrators to receive multi-admin verification.
   a. Click **Cluster > Settings.**
   b. Click → next to **Users and Roles.**
   c. Click + Add under **Users.**
   d. Modify the roster as needed.

      For more information, see Control administrator access.

2. Enable multi-admin verification by creating at least one approval group and adding at least one rule.
   a. Click **Cluster > Settings.**
   b. Click next to **Multi-Admin Approval** in the **Security** section.
   c. Click + Add to add at least one approval group.
      - Name – Enter a group name.
      - Approvers – Select approvers from a list of users.
      - Email address – Enter email address(es).
      - Default group – Select a group.
   d. Add at least one rule.
      - Operation – Select a supported command from the list.
      - Query – Enter any desired command options and values.
      - Optional parameters; leave blank to apply global settings, or assign a different value for specific rules to override the global settings.
        - Required number of approvers
        - Approval groups
   e. Click **Advanced Settings** to view or modify defaults.
      - Required number of approvers (default: 1)
      - Execution request expiry (default: 1 hour)
      - Approval request expiry (default: 1hour)
      - Mail server*
      - From email address*

        *These update the email settings managed under "Notification Management". You are prompted to set them if they have not yet been configured.

f. Click **Enable** to complete MAV initial configuration.

After initial configuration, the current MAV status is displayed in the **Multi-Admin Approval** tile.

- Status (enabled or not)
- Active operations for which approvals are required
- Number of open requests in pending state

You can display an existing configuration by clicking →. MAV approval is required to edit an existing configuration.

To disable multi-admin verification:

1. Click **Cluster > Settings.**
2. Click ⚙ next to **Multi-Admin Approval** in the **Security** section.
3. Click the Enabled toggle button.

   MAV approval is required to complete this operation.

CLI procedure

Before enabling MAV functionality at the CLI, at least one MAV administrator group must have been created.

If you want to…	Enter this command

Enable MAV functionality	`security multi-admin-verify modify -approval-groups` *group1*`[,`*group2*…`] [-required-approvers` *nn* `] -enabled true [ -execution-expiry [`*nn*`h][`*nn*`m][`*nn*`s]] [ -approval-expiry [`*nn*`h][`*nn*`m][`*nn*`s]]`
	
	Example : the following command enables MAV with 1 approval group, 2 required approvers, and default expiry periods.
	
	`cluster-1::> security multi-admin-verify modify -approval-groups mav-grp1 -required-approvers 2 -enabled true`
	
	Complete initial configuration by adding at least one operation rule.

Modify a MAV configuration (requires MAV approval)	`security multi-admin-verify approval-group modify [-approval-groups` *group1* `[,`*group2*…`]] [-required-approvers` *nn* `] [ -execution-expiry [`*nn*`h][`*nn*`m][`*nn*`s]] [ -approval-expiry [`*nn*`h][`*nn*`m][`*nn*`s]]`

If you want to…	Enter this command

Verify MAV functionality	`security multi-admin-verify show`
	
	Example:
	
	`cluster-1::> security multi-admin-verify show`
	`Is       Required  Execution`
	`Approval Approval`
	`Enabled Approvers Expiry    Expiry`
	`Groups`
	`------- --------- ---------`
	`-------- ----------`
	`true    2         1h        1h`
	`mav-grp1`

Disable MAV functionality (requires MAV approval)	`security multi-admin-verify modify -enabled false`

- security multi-admin-verify

Manage multi-admin verification rules for protected operations in ONTAP

You create multi-admin verification (MAV) rules to designate operations requiring approval. Whenever an operation is initiated, protected operations are intercepted and a request for approval is generated.

Rules can be created before enabling MAV by any administrator with appropriate RBAC capabilities, but once MAV is enabled, any modification to the rule set requires MAV approval.

Only one MAV rule can be created per operation; for example, you cannot make multiple `volume-snapshot-delete` rules. Any desired rule constraints must be contained within one rule.

You can create rules to protect these commands. You can protect each command beginning with the ONTAP version in which protection capability for the command first became available.

The rules for MAV system-default commands, the `security multi-admin-verify` commands, cannot be altered.

In addition to system-defined operations, the following commands are protected by default when multi-admin verification is enabled, but you can modify the rules to remove protection for these commands:

- security login password
- security login unlock
- set

Rule constraints

When you create a rule, you can optionally specify the `-query` option to limit the request to a subset of the command functionality. The `-query` option can also be used to limit configuration elements, such as the SVM, the volume, and snapshot names.

For example, in the `volume snapshot delete` command, `-query` can be set to `-snapshot !hourly*,!daily*,!weekly*`, meaning that volume snapshots prefixed with hourly, daily, or weekly attributes are excluded from MAV protections.

```
smci-vsim20::> security multi-admin-verify rule show
                                               Required  Approval
Vserver Operation                              Approvers Groups
------- -------------------------------------- --------- -------------
vs01    volume snapshot delete                 -         -
          Query: -snapshot !hourly*,!daily*,!weekly*
```

> Any excluded configuration elements would not be protected by MAV, and any administrator could delete or rename them.

By default, rules specify that a corresponding `security multi-admin-verify request create` *`"protected_operation"`* command is generated automatically when a protected operation is entered. You can modify this default to require that the `request create` command be entered separately.

By default, rules inherit the following global MAV settings, although you can specify rule-specific exceptions:

- Required Number of Approvers
- Approval Groups
- Approval Expiry period
- Execution Expiry period

System Manager procedure

If you want to add a protected operation rule for the first time, see the System Manager procedure to enable multi-admin verification.

To modify the existing rule set:

1. Select **Cluster > Settings**.
2. Select ⚙ next to **Multi-Admin Approval** in the **Security** section.
3. Select + Add to add at least one rule; you can also modify or delete existing rules.
   - Operation – Select a supported command from the list.
   - Query – Enter any desired command options and values.
   - Optional parameters – Leave blank to apply global settings, or assign a different value for specific rules to override the global settings.
     - Required number of approvers
     - Approval groups

CLI procedure

> All `security multi-admin-verify rule` commands require MAV administrator approval before execution except `security multi-admin-verify rule show`.

If you want to…	Enter this command
Create a rule	`security multi-admin-verify rule create -operation "protected_operation" [-query operation_subset] [parameters]`

Modify credentials of current administrators	`security login modify <parameters>`
	
	Example: the following rule requires approval to delete the root volume.
	
	`security multi-admin-verify rule create -operation "volume delete" -query "-vserver vs0"`

Modify a rule	`security multi-admin-verify rule modify -operation "protected_operation" [parameters]`
Delete a rule	`security multi-admin-verify rule delete -operation "protected_operation"`
Show rules	`security multi-admin-verify rule show`

Related information

- security multi-admin-verify rule
- security login modify

Request execution of MAV protected operations in ONTAP

When you initiate a protected operation or command on a cluster enabled for multi-admin verification (MAV), ONTAP automatically intercepts the operation and asks to generate a request, which must be approved by one or more administrators in a MAV approval group (MAV administrators). Alternatively, you can create a MAV request without the dialog.

If approved, you must then respond to the query to complete the operation within the request expiry period. If vetoed, or if the request or expiry periods are exceeded, you must delete the request and resubmit.

MAV functionality honors existing RBAC settings. That is, your administrator role must have sufficient privilege to execute a protected operation without regard to MAV settings. Learn more about RBAC.

If you are a MAV administrator, your requests to execute protected operations must also be approved by a MAV administrator.

System Manager procedure

When a user clicks on a menu item to initiate an operation and the operation is protected, a request for approval is generated and the user receives a notification similar to the following:

```
Approval request to delete the volume was sent.
Track the request ID 356 from Events & Jobs > Multi-Admin Requests.
```

The **Multi-Admin Requests** window is available when MAV is enabled, showing pending requests based on the user’s login ID and MAV role (approver or not). For each pending request, the following fields are displayed:

- Operation
- Index (number)
- Status (Pending, Approved, Rejected, Executed, or Expired)

  If a request is rejected by one approver, no further actions are possible.

- Query (any parameters or values for the requested operation)
- Requesting User
- Request Expires On
- (Number of) Pending Approvers
- (Number of) Potential Approvers

When the request is approved, the requesting user can retry the operation within the expiry period.

If the user retries the operation without approval, a notification is displayed similar to the following:

```
Request to perform delete operation is pending approval.
Retry the operation after request is approved.
```

CLI procedure

1. Enter the protected operation directly or using the MAV request command.

   Examples – to delete a volume, enter one of the following commands:

   - `volume delete`

```
cluster-1::*> volume delete -volume vol1 -vserver vs0

Warning: This operation requires multi-admin verification. To create
a
         verification request use "security multi-admin-verify
request
         create".

         Would you like to create a request for this operation?
          {y|n}: y

Error: command failed: The security multi-admin-verify request (index
3) is
       auto-generated and requires approval.
```

◦ `security multi-admin-verify request create "volume delete"`

```
Error: command failed: The security multi-admin-verify request (index
3)
       requires approval.
```

2. Check the status of the request and respond to the MAV notice.
   a. If the request is approved, respond to the CLI message to complete the operation.

      Example:

```
cluster-1::> security multi-admin-verify request show 3

     Request Index: 3
         Operation: volume delete
             Query: -vserver vs0 -volume vol1
             State: approved
Required Approvers: 1
 Pending Approvers: 0
   Approval Expiry: 2/25/2022 14:32:03
  Execution Expiry: 2/25/2022 14:35:36
         Approvals: admin2
       User Vetoed: -
           Vserver: cluster-1
    User Requested: admin
      Time Created: 2/25/2022 13:32:03
     Time Approved: 2/25/2022 13:35:36
           Comment: -
   Users Permitted: -

cluster-1::*> volume delete -volume vol1 -vserver vs0

Info: Volume "vol1" in Vserver "vs0" will be marked as deleted and
placed in the volume recovery queue. The space used by the volume
will be recovered only after the retention period of 12 hours has
completed. To recover the space immediately, get the volume name
using (privilege:advanced) "volume recovery-queue show vol1_*" and
then "volume recovery-queue purge -vserver vs0 -volume <volume_name>"
command. To recover the volume use the (privilege:advanced) "volume
recovery-queue recover -vserver vs0       -volume <volume_name>"
command.

Warning: Are you sure you want to delete volume "vol1" in Vserver
"vs0" ?
{y|n}: y
```

b. If the request is vetoed, or the expiry period has passed, delete the request, and either resubmit or contact the MAV administrator.

Example:

```
cluster-1::> security multi-admin-verify request show 3

     Request Index: 3
         Operation: volume delete
             Query: -vserver vs0 -volume vol1
             State: vetoed
Required Approvers: 1
 Pending Approvers: 1
   Approval Expiry: 2/25/2022 14:38:47
  Execution Expiry: -
         Approvals: -
       User Vetoed: admin2
           Vserver: cluster-1
    User Requested: admin
      Time Created: 2/25/2022 13:38:47
     Time Approved: -
           Comment: -
   Users Permitted: -

cluster-1::*> volume delete -volume vol1 -vserver vs0

Error: command failed: The security multi-admin-verify request (index
3) hasbeen vetoed. You must delete it and create a new verification
request.
To delete, run "security multi-admin-verify request delete 3".
```

Manage MAV protected operation requests in ONTAP

When administrators in a MAV approval group (MAV administrators) are notified of a pending operation execution request, they must respond with an approve or veto message within a fixed time (approval expiry). If a sufficient number of approvals are not received, the requester must delete the request and make another.

About this task

Approval requests are identified with index numbers, which are included in email messages and displays of the request queue.

The following information from the request queue can be displayed:

Operation

The protected operation for which the request is created.

Query

The object (or objects) upon which the user wants to apply the operation.

State

The current state of the request; pending, approved, rejected, expired, executed. If a request is rejected by one approver, no further actions are possible.

Required approvers

The number of MAV administrators that are required to approve the request. A user can set the required-approvers parameter for the operation rule. If a user does not set the required-approvers to the rule, then the required-approvers from the global setting is applied.

Pending approvers

The number of MAV administrators that are still required to approve the request for the request to be marked as approved.

Approval expiry

The period within which a MAV administrator must respond to an approval request. Any authorized user can set the approval-expiry for an operation rule. If approval-expiry is not set for the rule, then the approval-expiry from the global setting is applied.

Execution expiry

The period within which the requesting administrator must complete the operation. Any authorized user can set the execution-expiry for an operation rule. If execution-expiry is not set for the rule, then the execution-expiry from the global setting is applied.

Users approved

The MAV administrators who have approved the request.

User vetoed

The MAV administrators who have vetoed the request.

Storage VM (vserver)

The SVM with which the request is associated with. Only the admin SVM is supported in this release.

User requested

The username of the user who created the request.

Time created

The time when the request is created.

Time approved

The time when the request state changed to approved.

Comment

Any comments that are associated with the request.

Users permitted

The list of users permitted to perform the protected operation for which the request is approved. If `users-permitted` is empty, then any user with appropriate permissions can perform the operation.

Request deletion

When a new admin request is created, the system checks an existing request for deletion based on the following criteria:

- The request must be expired or executed.
- If the request is more than one day old from its approval expiry time, it is deleted.
- If there are more than 1000 requests in the table, an older request is deleted to maintain the limit.

If the number of requests exceeds 1000 after this cleanup, a warning is issued to administrators.

System Manager

MAV administrators receive email messages with details of the approval request, request expiry period, and a link to approve or reject the request. They can access an approval dialog by clicking the link in the email or navigate to **Events & Jobs>Requests** in System Manager.

The **Requests** window is available when multi-admin verification is enabled, showing pending requests based on the user's login ID and MAV role (approver or not).

- Operation
- Index (number)
- Status (Pending, Approved, Rejected, Executed, or Expired)

  If a request is rejected by one approver, no further actions are possible.

- Query (any parameters or values for the requested operation)
- Requesting User
- Request Expires On
- (Number of) Pending Approvers
- (Number of) Potential Approvers

MAV administrators have additional controls in this window; they can approve, reject, or delete individual operations, or selected groups of operations. However, if the MAV administrator is the Requesting User, they cannot approve, reject or delete their own requests.

CLI

1. When notified of pending requests by email, note the request's index number and approval expiry period. The index number can also be displayed using the **show** or **show-pending** options mentioned below.
2. Approve or veto the request.

If you want to…	Enter this command
Approve a request	`security multi-admin-verify request approve` *nn*
Veto a request	`security multi-admin-verify request veto` *nn*

If you want to…	Enter this command
Show all requests, pending requests, or a single request	`security multi-admin-verify request { show | show-pending } [nn] { -fields field1[,field2…] | [-instance ] }` You can show all requests in the queue or only pending requests. If you enter the index number, only information for that is displayed. You can display information about specific fields (by using the `-fields` parameter) or about all fields (by using the `-instance` parameter).
Delete a request	`security multi-admin-verify request delete nn`

Example:

The following sequence approves a request after the MAV administrator has received the request email with index number 3, which already has one approval.

```
          cluster1::> security multi-admin-verify request show-pending
                                   Pending
Index Operation      Query State   Approvers Requestor
----- -------------- ----- ------- --------- ---------
    3 volume delete  -     pending 1         julia

cluster-1::> security multi-admin-verify request approve 3

cluster-1::> security multi-admin-verify request show 3

     Request Index: 3
         Operation: volume delete
             Query: -
             State: approved
Required Approvers: 2
 Pending Approvers: 0
   Approval Expiry: 2/25/2022 14:32:03
  Execution Expiry: 2/25/2022 14:35:36
         Approvals: mav-admin2
       User Vetoed: -
           Vserver: cluster-1
    User Requested: julia
      Time Created: 2/25/2022 13:32:03
     Time Approved: 2/25/2022 13:35:36
           Comment: -
   Users Permitted: -
```

Example:

The following sequence vetoes a request after the MAV administrator has received the request email with index number 3, which already has one approval.

```
      cluster1::> security multi-admin-verify request show-pending
                                   Pending
Index Operation      Query State   Approvers Requestor
----- -------------- ----- ------- --------- ---------
    3 volume delete  -     pending 1         pavan

cluster-1::> security multi-admin-verify request veto 3

cluster-1::> security multi-admin-verify request show 3

     Request Index: 3
         Operation: volume delete
             Query: -
             State: vetoed
Required Approvers: 2
 Pending Approvers: 0
   Approval Expiry: 2/25/2022 14:32:03
  Execution Expiry: 2/25/2022 14:35:36
         Approvals: mav-admin1
       User Vetoed: mav-admin2
           Vserver: cluster-1
    User Requested: pavan
      Time Created: 2/25/2022 13:32:03
     Time Approved: 2/25/2022 13:35:36
           Comment: -
   Users Permitted: -

Manage dynamic authorization

Learn about ONTAP dynamic authorization

Beginning with ONTAP 9.15.1, administrators can configure and enable dynamic authorization to increase security of remote access to ONTAP while also mitigating potential damage that could be caused by a malicious actor. With ONTAP 9.15.1, dynamic authorization provides an initial framework for assigning a security score to users and, if their activity looks suspicious, challenging them with additional authorization checks or denying an operation completely. Administrators can create rules, assign trust scores, and restrict commands to determine when certain activity is allowed or denied for a user. Administrators can enable dynamic authorization cluster-wide or for individual storage VMs.

How dynamic authorization works

Dynamic authorization uses a trust scoring system to assign users a different level of trust depending on the authorization policies. Based on the user's trust level, an activity they perform can be allowed or denied, or the user can be prompted for further authentication.

Refer to Customize dynamic authorization to learn more about how to configure criteria score weights and other dynamic authorization attributes.

Trusted devices

When dynamic authorization is in use, the definition of a trusted device is a device used by a user to log in to ONTAP using public key authentication as one of the authentication methods. The device is trusted because only that user has possession of the corresponding private key.

Dynamic authorization example

Take the example of three different users attempting to delete a volume. When they try to perform the operation, the risk rating for each user is examined:

- The first user logs in from a trusted device with very few previous authentication failures, which makes her risk rating low; the operation is allowed without additional authentication.
- The second user logs in from a trusted device with a moderate percentage of previous authentication failures, which makes the risk rating moderate; she is prompted for additional authentication before the operation is allowed.
- The third user logs in from an untrusted device with a high percentage of previous authentication failures, which makes the risk rating high; the operation is not allowed.

What's next

- Enable or disable dynamic authorization
- Customize dynamic authorization

Enable or disable dynamic authorization in ONTAP

Beginning with ONTAP 9.15.1, administrators can configure and enable dynamic authorization either in `visibility` mode to test the configuration, or in `enforced` mode to activate the configuration for CLI users connecting over SSH. If you no longer need dynamic authorization, you can disable it. When you disable dynamic authorization, the configuration settings remain available and you can use them later if you decide to re-enable it.

Learn more about `security dynamic-authorization modify` in the ONTAP command reference.

Enable dynamic authorization for testing

You can enable dynamic authorization in visibility mode, which enables you to test the feature and ensure that users will not be accidentally locked out. In this mode, the trust score is checked with every restricted activity, but not enforced. However, any activity that would have been denied or subject to additional authentication challenges is logged. As a best practice, you should test your intended settings in this mode before enforcing them.

You can follow this step to enable dynamic authorization for the first time even if you haven't yet configured any other dynamic authorization settings. Refer to Customize dynamic authorization for steps to configure other dynamic authorization settings to customize it to your environment.

Steps

1. Enable dynamic authorization in visibility mode by configuring global settings and changing the feature state to `visibility`. If you don't use the `-vserver` parameter, the command is run at the cluster level. Update the values in brackets <> to match your environment. Parameters in bold are required:

```
security dynamic-authorization modify \
<strong>-state visibility</strong> \
-lower-challenge-boundary <percent> \
-upper-challenge-boundary <percent> \
-suppression-interval <interval> \
-vserver <storage_VM_name>
```

2. Check the result by using the `show` command to display the global configuration:

```
security dynamic-authorization show
```

Enable dynamic authorization in enforced mode

You can enable dynamic authorization in enforced mode. Typically, you use this mode after you have completed testing with visibility mode. In this mode, the trust score is checked with every restricted activity, and activity restrictions are enforced if the restriction conditions are met. The suppression interval is also enforced, preventing additional authentication challenges within the specified interval.

This step assumes that you have previously configured and enabled dynamic authorization in `visibility` mode, which is strongly recommended.

Steps

1. Enable dynamic authorization in `enforced` mode by changing its state to `enforced`. If you don't use the `-vserver` parameter, the command is run at the cluster level. Update the values in brackets <> to match your environment. Parameters in bold are required:

```
security dynamic-authorization modify \
<strong>-state enforced</strong> \
-vserver <storage_VM_name>
```

2. Check the result by using the `show` command to display the global configuration:

```
security dynamic-authorization show
```

Disable dynamic authorization

You can disable dynamic authorization if you no longer need the added authentication security.

Steps

1. Disable dynamic authorization by changing its state to `disabled`. If you don't use the `-vserver` parameter, the command is run at the cluster level. Update the values in brackets <> to match your environment. Parameters in bold are required:

```
security dynamic-authorization modify \
<strong>-state disabled</strong> \
-vserver <storage_VM_name>
```

2. Check the result by using the `show` command to display the global configuration:

```
security dynamic-authorization show
```

Learn more about `security dynamic-authorization show` in the ONTAP command reference.

What's next

(Optional) Depending on your environment, refer to Customize dynamic authorization to configure other dynamic authorization settings.

Customize dynamic authorization in ONTAP

As an administrator, you can customize different aspects of your dynamic authorization configuration to increase the security of remote administrator SSH connections to your ONTAP cluster.

You can customize the following dynamic authorization settings depending on your security needs:

- Configure dynamic authorization global settings
- Configure dynamic authorization trust score components
- Configure a custom trust score provider
- Configure restricted commands
- Configure dynamic authorization groups

Configure dynamic authorization global settings

You can configure global settings for dynamic authorization, including the storage VM to secure, the suppression interval for authentication challenges, and the trust score settings.

Learn more about `security login domain-tunnel create` in the ONTAP command reference.

Steps

1. Configure global settings for dynamic authorization. If you don't use the `-vserver` parameter, the

command is run at the cluster level. Update the values in brackets <> to match your environment:

```
security dynamic-authorization modify \
-lower-challenge-boundary <percent> \
-upper-challenge-boundary <percent> \
-suppression-interval <interval> \
-vserver <storage_VM_name>
```

2. View the resulting configuration:

```
security dynamic-authorization show
```

Configure restricted commands

When you enable dynamic authorization, the feature includes a default set of restricted commands. You can modify this list to suit your needs. Refer to the multi-admin verification (MAV) documentation for information on the default list of restricted commands.

Add a restricted command

You can add a command to the list of commands that are restricted with dynamic authorization.

Learn more about `security dynamic-authorization rule create` in the ONTAP command reference.

Steps

1. Add the command. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization rule create \
-query <query> \
<strong>-operation <text></strong> \
-index <integer> \
-vserver <storage_VM_name>
```

2. View the resulting list of restricted commands:

```
security dynamic-authorization rule show
```

Remove a restricted command

You can remove a command from the list of commands that are restricted with dynamic authorization.

Learn more about `security dynamic-authorization rule delete` in the ONTAP command reference.

Steps

1. Remove the command. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization rule delete \
<strong>-operation <text></strong> \
-vserver <storage_VM_name>
```

2. View the resulting list of restricted commands:

```
security dynamic-authorization rule show
```

Configure dynamic authorization groups

By default, dynamic authorization applies to all users and groups as soon as you enable it. However, you can create groups using the `security dynamic-authorization group create` command, so that dynamic authorization only applies to those specific users.

Add a dynamic authorization group

You can add a dynamic authorization group.

Learn more about `security dynamic-authorization group create` in the ONTAP command reference.

Steps

1. Create the group. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization group create \
<strong>-name <group-name></strong> \
-vserver <storage_VM_name> \
-excluded-usernames <user1,user2,user3...>
```

2. View the resulting dynamic authorization groups:

```
security dynamic-authorization group show
```

Remove a dynamic authorization group

You can remove a dynamic authorization group.

Learn more about `security dynamic-authorization group delete` in the ONTAP command reference.

Steps

1. Delete the group. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization group delete \
<strong>-name <group-name></strong> \
-vserver <storage_VM_name>
```

2. View the resulting dynamic authorization groups:

```
security dynamic-authorization group show
```

Configure dynamic authorization trust score components

You can configure the maximum score weight to change priority of scoring criteria or to remove certain criteria from risk scoring.

> ⓘ As a best practice, you should leave the default score weight values in place, and only adjust them if needed.

Learn more about `security dynamic-authorization trust-score-component modify` in the ONTAP command reference.

The following are the components that you can modify, along with their default score and percentage weights:

Criteria	Component name	Default raw score weight	Default percentage weight
Trusted device	`trusted-device`	20	50
User login authentication history	`authentication-history`	20	50

Steps

1. Modify trust score components. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization trust-score-component modify \
<strong>-component <component-name></strong> \
<strong>-weight <integer></strong> \
-vserver <storage_VM_name>
```

2. View the resulting trust score component settings:

```
security dynamic-authorization trust-score-component show
```

Reset the trust score for a user

If a user is denied access due to system policies and is able to prove their identity, the administrator can reset the user's trust score.

Learn more about `security dynamic-authorization user-trust-score reset` in the ONTAP command reference.

Steps

1. Add the command. Refer to Configure dynamic authorization trust score components for a list of trust score components that you can reset. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization user-trust-score reset \
<strong>-username <username></strong> \
<strong>-component <component-name></strong> \
-vserver <storage_VM_name>
```

Display your trust score

A user can display their own trust score for a login session.

Steps

1. Display your trust score:

```
security login whoami
```

You should see output similar to the following:

```
User: admin
Role: admin
Trust Score: 50
```

Learn more about `security login whoami` in the ONTAP command reference.

Configure a custom trust score provider

If you already receive scoring methods from an external trust score provider, you can add the custom provider to the dynamic authorization configuration.

Before you begin

- The custom trust score provider must return a JSON response. The following syntax requirements must be met:
  - The field that returns the trust score must be a scalar field and not an element of an array.
  - The field that returns the trust score can be a nested field, such as `trust_score.value`.

◦ There must be a field within the JSON response that returns a numeric trust score. If this is not natively available, you can write a wrapper script to return this value.

- The value provided can be either a trust score or a risk score. The difference is that the trust score is in ascending order with a higher score denoting a higher trust level, while the risk score is in descending order. For example, a trust score of 90 for a score range of 0 to 100 indicates that the score is very trustworthy and likely to result in an "allow" without additional challenge, while a risk score of 90 for a score range of 0 to 100 indicates high risk and likely to result in a "deny" without an additional challenge.
- The custom trust score provider must be accessible via the ONTAP REST API.
- The custom trust score provider must be configurable using one of the supported parameters. Custom trust score providers that require configuration that is not in the supported parameter list are not supported.

  Learn more about `security dynamic-authorization trust-score-component create` in the ONTAP command reference.

Steps

1. Add a custom trust score provider. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization trust-score-component create \
-component <text> \
<strong>-provider-uri <text></strong> \
-score-field <text> \
-min-score <integer> \
<strong>-max-score <integer></strong> \
<strong>-weight <integer></strong> \
-secret-access-key "<key_text>" \
-provider-http-headers <list<header,header,header>> \
-vserver <storage_VM_name>
```

2. View the resulting trust score provider settings:

```
security dynamic-authorization trust-score-component show
```

Configure custom trust score provider tags

You can communicate with external trust score providers using tags. This enables you to send information in the URL to the trust score provider without exposing sensitive information.

Learn more about `security dynamic-authorization trust-score-component create` in the ONTAP command reference.

Steps

1. Enable trust score provider tags. Update the values in brackets <> to match your environment. If you don't use the `-vserver` parameter, the command is run at the cluster level. Parameters in bold are required:

```
security dynamic-authorization trust-score-component create \
<strong>-component <component_name></strong> \
-weight <initial_score_weight> \
-max-score <max_score_for_provider> \
<strong>-provider-uri <provider_URI></strong> \
-score-field <REST_API_score_field> \
<strong>-secret-access-key "<key_text>"</strong>
```

For example:

```
security dynamic-authorization trust-score-component create -component
comp1 -weight 20 -max-score 100 -provider-uri https://<url>/trust-
scores/users/<user>/<ip>/component1.html?api-key=<access-key> -score
-field score -access-key "MIIBBjCBrAIBArqyTHFvYdWiOpLkLKHGjUYUNSwfzX"
```

Authentication and authorization using OAuth 2.0

Overview of the ONTAP OAuth 2.0 implementation

Beginning with ONTAP 9.14, you have the option to control access to your ONTAP clusters using the Open Authorization (OAuth 2.0) framework. You can configure this feature using any of the ONTAP administrative interfaces, including the ONTAP CLI, System Manager, and REST API. However, the OAuth 2.0 authorization and access control decisions can only be applied when a client accesses ONTAP using the REST API.

> OAuth 2.0 support was first introduced with ONTAP 9.14.0 and so its availability depends on the ONTAP release you are using. See the ONTAP release notes for more information.

Features and benefits

The major features and benefits of using OAuth 2.0 with ONTAP are described below.

Support for the OAuth 2.0 standard

OAuth 2.0 is the industry standard authorization framework. It is used to restrict and control access to protected resources using signed access tokens. There are several benefits to using OAuth 2.0:

- Many options for the authorization configuration
- Never reveal the client credentials including passwords
- Tokens can be set to expire based on your configuration
- Ideally suited for use with REST APIs

Tested with popular authorization servers

The ONTAP OAuth 2.0 implementation has been tested with several popular servers or services based on the

ONTAP release as follows:

- ONTAP 9.16.1 (support for group UUID to name mapping and external roles):
  - Microsoft Entra ID
- ONTAP 9.14.1 (support for standard OAuth 2.0 features)
  - Auth0
  - Active Directory Federation Service (ADFS)
  - Keycloak

See Authorization servers and access tokens for more details about the features and capabilities available with each ONTAP release.

Support for multiple concurrent authorization servers

You can define up to eight authorization servers for a single ONTAP cluster. This gives you the flexibility to meet the needs of your diverse security environment.

Integration with the REST roles

The ONTAP authorization decisions are ultimately based on the REST roles assigned to users or groups. These roles are either carried in the access token as self-contained scopes or based on local ONTAP definitions along with Active Directory or LDAP groups.

Option to use sender-constrained access tokens

You can configure ONTAP and the authorization servers to use Mutual Transport Layer Security (mTLS) which strengthens client authentication. It guarantees the OAuth 2.0 access tokens are only used by the clients to which they were originally issued. This feature supports and aligns with several popular security recommendations, including those established by FAPI and MITRE.

Implementation and configuration

At a high level, there are several aspects of an OAuth 2.0 implementation and configuration you should consider when getting started.

OAuth 2.0 entities within ONTAP

The OAuth 2.0 authorization framework defines several entities that can be mapped to real or virtual elements within your data center or network. The OAuth 2.0 entities and their adaptation to ONTAP are presented in the table below.

OAuth 2.0 Entity	Description
Resource	The REST API endpoints that provide access to the ONTAP resources through internal ONTAP commands.
Resource owner	The ONTAP cluster user that created the protected resource or owns it by default.
Resource server	The host for the protected resources which is the ONTAP cluster.
Client	An application requesting access to a REST API endpoint on behalf of or with permission from the resource owner.
Authorization server	Typically a dedicated server responsible for issuing access tokens and enforcing administrative policy.

Core ONTAP configuration

You need to configure the ONTAP cluster to enable and use OAuth 2.0. This includes establishing a connection to the authorization server and defining the required ONTAP authorization configuration. You can perform this configuration using any of the administrative interfaces, including:

- ONTAP command line interface
- System Manager
- ONTAP REST API

Environment and supporting services

In addition to the ONTAP definitions, you also need to configure the authorization servers. If you're using group-to-role mapping, you need also to configure the Active Directory groups or LDAP equivalent.

Supported ONTAP clients

Beginning with ONTAP 9.14, a REST API client can access ONTAP using OAuth 2.0. Before issuing a REST API call, you need to obtain an access token from the authorization server. The client then passes this token to the ONTAP cluster as a *bearer token* using the HTTP authorization request header. Depending on the level of security needed, you can also create and install a certificate at the client to use sender-constrained tokens based on mTLS.

Selected terminology

As you begin exploring an OAuth 2.0 deployment with ONTAP, it is helpful to become familiar with some of the terminology. See Additional resources for links to more information about OAuth 2.0.

Access token
A token issued by an authorization server and used by an OAuth 2.0 client application to make requests to access the protected resources.

JSON Web Token
The standard used to format the access tokens. JSON is used to represent the OAuth 2.0 claims in a compact format with the claims arranged in three main sections.

Sender-constrained access token
An optional feature based on the Mutual Transport Layer Security (mTLS) protocol. By using an additional confirmation claim in the token, this ensures the access token is only used by the client to which it was originally issued.

JSON Web Key Set
A JWKS is a collection of public keys used by ONTAP to verify the JWT tokens presented by the clients. The key sets are typically available at the authorization server through a dedicated URI.

Scope
Scopes provide a way to limit or control an application's access to protected resources such as the ONTAP REST API. They are represented as strings in the access token.

ONTAP REST role
REST roles were introduced with ONTAP 9.6 and are a core part of the ONTAP RBAC framework. These roles are different than the earlier traditional roles which are still supported by ONTAP. The OAuth 2.0 implementation in ONTAP only supports REST roles.

HTTP authorization header

A header included in the HTTP request to identify the client and associated permissions as part of making a REST API call. There are several flavors or implementations available depending on how authentication and authorization is performed. When presenting an OAuth 2.0 access token to ONTAP, the token is identified as a *bearer token*.

HTTP basic authentication

An early HTTP authentication technique still supported by ONTAP. The plaintext credentials (username and password) are concatenated with a colon and encoded in base64. The string is placed in the authorization request header and sent to the server.

FAPI

A working group at the OpenID Foundation providing protocols, data schemas, and security recommendations for the financial industry. The API was originally known as the Financial Grade API.

MITRE

A private not-for-profit company providing technical and security guidance to the United States Air Force and US government.

Additional resources

Several additional resources are provided below. You should review these sites to get more information about OAuth 2.0 and the related standards.

Protocols and standards

- RFC 6749: The OAuth 2.0 Authorization Framework

Concepts

OAuth 2.0 authorization servers and access tokens in ONTAP

Authorization servers perform several important functions as a central component within the OAuth 2.0 Authorization framework.

OAuth 2.0 authorization servers

Authorization servers are primarily responsible for creating and signing access tokens. These tokens contain identity and authorization information enabling a client application to selectively access protected resources. The servers are generally isolated from one another and can be implemented in several different ways, including as a standalone dedicated server or as part of a larger identity and access management product.

> Different terminology can sometimes be used for an authorization server, especially when the OAuth 2.0 functionality is packaged within a larger identity and access management product or solution. For example, the term **identity provider (IdP)** is frequently used interchangeably with **authorization server**.

Administration

In addition to issuing access tokens, authorization servers also provide related administrative services, typically through a web user interface. For example, you can define and administer:

* Users and user authentication
* Scopes
* Administrative segregation through tenants and realms
* Policy enforcement
* Connection to various external services
* Support for other identity protocols (such as SAML)

ONTAP is compatible with authorization servers that are compliant with the OAuth 2.0 standard.

Defining to ONTAP

You need to define one or more authorization servers to ONTAP. ONTAP securely communicates with each server to verify tokens and perform other related tasks in support of the client applications.

The major aspects of ONTAP configuration are presented below. Also see OAuth 2.0 deployment scenarios for more information.

How and where the access tokens are validated

There are two options for validating access tokens.

* Local validation

  ONTAP can validate access tokens locally based on information provided by the authorization server that issued the token. The information retrieved from the authorization server is cached by ONTAP and refreshed at regular intervals.

- Remote introspection

  You can also use remote introspection to validate tokens at the authorization server. Introspection is a protocol allowing authorized parties to query an authorization server about an access token. It provides ONTAP a way to extract certain metadata from an access token and validate the token. ONTAP caches some of the data for performance reasons.

Network location

ONTAP may be behind a firewall. In this case, you need to identify a proxy as part of the configuration.

How the authorization servers are defined

You can define an authorization server to ONTAP using any of the administrative interfaces, including the CLI, System Manager, or REST API. For example, with the CLI you use the command `security oauth2 client create`.

Learn more about `security oauth2 client create` in the ONTAP command reference.

Number of authorization servers

You can define up to eight authorization servers to a single ONTAP cluster. The same authorization server can be defined more than once to the same ONTAP cluster as long as the issuer or issuer/audience claims are unique. For example, with Keycloak this will always be the case when using different realms.

OAuth 2.0 features supported in ONTAP

Support for OAuth 2.0 was initially available with ONTAP 9.14.1 and continues to be enhanced with subsequent releases. The OAuth 2.0 features supported by ONTAP are described below.

> Features introduced with a specific ONTAP release are carried forward to future releases.

ONTAP 9.16.1

ONTAP 9.16.1 expands the standard OAuth 2.0 features to include Entra ID specific extensions for native Entra ID groups. This involves the use of GUIDs in the access token instead of names. In addition, the release adds support for external role mapping to map the native identity provider roles to ONTAP roles using the "roles" field in the access token.

ONTAP 9.14.1

Beginning with ONTAP 9.14.1, authorization servers are supported through the following standard OAuth 2.0 features for applications using:

- OAuth 2.0 with the standard fields including "iss", "aud", and "exp" as described in RFC6749: The OAuth 2.0 Authorization Framework and RFC 7519: JSON Web Token (JWT). This also includes support for uniquely identifying users through fields in the access token such as "upn", "appid", "sub", "username" or "preferred_username".
- ADFS vendor-specific extensions for group names with the "group" field.
- Azure vendor-specific extensions for group UUIDs with the "group" field.
- ONTAP extensions for authorization support using self-contained and named roles within the OAuth 2.0 access token scope. This includes the "scope" and "scp" fields as well as group names within the scope.

Using OAuth 2.0 access tokens

The OAuth 2.0 access tokens issued by the authorization servers are verified by ONTAP and used to make role-based access decisions for the REST API client requests.

Acquiring an access token

You need to acquire an access token from an authorization server defined to the ONTAP cluster where you use the REST API. To acquire a token, you must contact the authorization server directly.

> ONTAP does not issue access tokens or redirect requests from clients to the authorization servers.

How you request a token depends on several factors, including:

- Authorization server and its configuration options
- OAuth 2.0 grant type
- Client or software tool used to issue the request

Grant types

A *grant* is a well-defined process, including a set of network flows, used to request and receive an OAuth 2.0 access token. Several different grant types can be used depending on the client, environment, and security requirements. A list of the popular grant types is presented in the table below.

Grant type	Description
Client credentials	A popular grant type based on using only credentials (such as an ID and shared secret). The client is assumed to have a close trust relationship with the resource owner.
Password	The resource owner password credentials grant type can be used in cases where the resource owner has an established trust relation with the client. It can also be useful when migrating legacy HTTP clients to OAuth 2.0.
Authorization code	This is an ideal grant type for confidential clients and is based on a redirection-based flow. It can be used to obtain both an access token and refresh token.

JWT contents

An OAuth 2.0 access token is formatted as a JWT. The content is created by the authorization server based on your configuration. However, the tokens are opaque to the client applications. A client has no reason to inspect a token or to be aware of the contents.

Each JWT access token contains a set of claims. The claims describe characteristics of the issuer and the authorization based on administrative definitions at the authorization server. Some of the claims registered with the standard are described in the table below. All the strings are case sensitive.

Claim	Keyword	Description
Issuer	iss	Identifies the principal that issued the token. The claim processing is application specific.

Claim	Keyword	Description
Subject	sub	The subject or user of the token. The name is scoped to be globally or locally unique.
Audience	aud	The recipients the token is intended for. Implemented as an array of strings.
Expiration	exp	The time after which the token expires and must be rejected.

See RFC 7519: JSON Web Tokens for more information.

Client authorization

Overview and options for ONTAP client authorization

The ONTAP OAuth 2.0 implementation is designed to be flexible and robust, providing the features you need to secure your ONTAP environment. There are several mutually exclusive configuration options available. The authorization decisions are ultimately based on the ONTAP REST roles either contained in or derived from the OAuth 2.0 access tokens.

> You can only use ONTAP REST roles when configuring authorization for OAuth 2.0. The earlier ONTAP traditional roles are not supported.

ONTAP applies the single most appropriate authorization option based on your configuration. See How ONTAP determines access for more about how ONTAP makes client access decisions.

OAuth 2.0 self-contained scopes

These scopes contain one or more custom REST roles, each encapsulated within a single string in the access token. They are independent of the ONTAP role definitions. You need to configure the scope strings at your authorization server. See Self-contained OAuth 2.0 scopes for more information.

Local ONTAP REST roles

A single named REST role, either builtin or custom, can be used. The scope syntax for a named role is **ontap-role-**<URL-encoded-ONTAP-role-name>. For example, if the ONTAP role is `admin` the scope string will be `ontap-role-admin`.

Users

The username in the access token defined with access to the application "http" can be used. A user is tested in the following order based on the defined authentication method: password, domain (Active Directory), nsswitch (LDAP).

Groups

The authorization servers can be configured to use ONTAP groups for authorization. If the local ONTAP definitions are examined but no access decision can be made, the Active Directory ("domain") or LDAP ("nsswitch") groups are used. Group information can be specified in one of two ways:

- OAuth 2.0 scope string

  Supports confidential applications using the client credentials flow where there is no user with a group membership. The scope should be named **ontap-group-**<URL-encoded-ONTAP-group-name>. For example, if the group is "development" the scope string will be "ontap-group-development".

- In the "group" claim

  This is intended for access tokens issued by ADFS using the resource owner (password grant) flow.

See Working with OAuth 2.0 or SAML IdP groups in ONTAP for more information.

Self-contained OAuth 2.0 scopes in ONTAP

Self-contained scopes are strings carried in the access token. Each is a complete custom role definition and includes everything ONTAP needs to make an access decision. The scope is separate and distinct from any of the REST roles defined within ONTAP itself.

Format of the scope string

At a base level, the scope is represented as a contiguous string and composed of six colon-separated values. The parameters used in the scope string are described below.

ONTAP literal

The scope must begin with the literal value `ontap` in lowercase. This identifies the scope as specific to ONTAP.

Cluster

This defines which ONTAP cluster the scope applies to. The values can include:

- Cluster UUID

  Identifies a single cluster.

- Asterisk (*)

  Indicates the scope applies to all clusters.

You can use the ONTAP CLI command `cluster identity show` to display the UUID of your cluster. If not specified, the scope applies to all clusters. Learn more about `cluster identity show` in the ONTAP command reference.

Role

The name of the REST role contained in the self-contained scope. This value is not examined by ONTAP or matched to any existing REST roles defined to ONTAP. The name is used for logging.

Access level

This value indicates the access level applied to the client application when using the API endpoint in the scope. There are six possible values as described in the table below.

Access level	Description
none	Denies all access to the specified endpoint.
readonly	Allows only read access using GET.

Access level	Description
read_create	Allows read access as well as the creation of new resource instances using POST.
read_modify	Allows read access as well as the ability to update existing resources using PATCH.
read_create_modify	Allows all access except delete. The allowed operations include GET (read), POST (create), and PATCH (update).
all	Allows full access.

SVM

The name of the SVM within the cluster the scope applies to. Use the * value (asterisk) to indicate all SVMs.

> This feature is not fully supported with ONTAP 9.14.1. You can ignore the SVM parameter and use an asterisk as a placeholder. Review the ONTAP release notes to check for future SVM support.

REST API URI

The complete or partial path to a resource or set of related resources. The string must begin with `/api`. If you don't specify a value, the scope applies to all API endpoints at the ONTAP cluster.

Scope examples

A few examples of self-contained scopes are presented below.

ontap:*:joes-role:read_create_modify:*:/api/cluster

Provides the user assigned this role read, create, and modify access to the `/cluster` endpoint.

CLI administrative tool

To make the administration of the self-contained scopes easier and less error-prone, ONTAP provides the CLI command `security oauth2 scope` to generate scope strings based on your input parameters.

The command `security oauth2 scope` has two use cases based on your input:

- CLI parameters to scope string

  You can use this version of the command to generate a scope string based on the input parameters.

- Scope string to CLI parameters

  You can use this version of the command to generate the command parameters based on the input scope string.

Example

The following example generates a scope string with the output included after the command example below. The definition applies to all clusters.

```
security oauth2 scope cli-to-scope -role joes-role -access readonly -api
/api/cluster
```

`ontap:*:joes-role:readonly:*:/api/cluster`

Learn more about `security oauth2 scope` in the ONTAP command reference.

OAuth 2.0 external role mapping in ONTAP

An external role is defined at an identify provider configured for use by ONTAP. You can create and administer mapping relationships between these external roles and the ONTAP roles using the ONTAP CLI.

> You can also configure the external role mapping feature using the ONTAP REST API. Learn more in the ONTAP automation documentation.

External roles in an access token

Here's a fragment of a JSON access token containing two external roles.

```
...
"appidacr": "1",
"family_name": "User",
"name": "Test User 1",
"oid": "4c2215c7-6d52-40a7-ce71-096fa41379ba",
"roles": [
  "Global Administrator",
  "Application Administrator"
],
"ver": "1.0",
...
```

Configuration

You can use the ONTAP command line interface to administer the external role mapping feature.

Create

You can define a role mapping configuration with the `security login external-role-mapping create` command. You need to be at the ONTAP **admin** privilege level to issue this command as well as the related options.

Parameters

The parameters used to create a group mapping are described below.

Parameter	Description
`external-role`	The name of the role defined at the external identity provider.
`provider`	The name of the identity provider. This should be the identifier for the system.
`ontap-role`	Indicates the existing ONTAP role the external role is mapped to.

Example

```
security login external-role-mapping create -external-role "Global
Administrator" -provider entra -ontap-role admin
```

How ONTAP determines client access

To properly design and implement OAuth 2.0, you need to understand how your authorization configuration is used by ONTAP to make access decisions for the clients. The major steps used to determine access are presented below based on the ONTAP release.

> ⓘ There were no significant OAuth 2.0 updates with ONTAP 9.15.1. If you are using the 9.15.1 release, refer to the description for ONTAP 9.14.1.

Related information

- OAuth 2.0 features supported in ONTAP

ONTAP 9.16.1

ONTAP 9.16.1 expands the standard OAuth 2.0 support to include Microsoft Entra ID specific extensions for native Entra ID groups as well as external role mapping.

Determine client access for ONTAP 9.16.1

Step 1: Self-contained scopes

If the access token contains any self-contained scopes, ONTAP examines these scopes first. If there are no self-contained scopes, go to step 2.

With one or more self-contained scopes present, ONTAP applies each scope until an explicit **ALLOW** or **DENY** decision can be made. If an explicit decision is made, processing ends.

If ONTAP can't make an explicit access decision, continue to step 2.

Step 2: Check the local roles flag

ONTAP examines the boolean parameter `use-local-roles-if-present`. The value of this flag is set separately for each authorization server defined to ONTAP.

- If the value is `true` continue to step 3.
- If the value is `false` processing ends and access is denied.

Step 3: Named ONTAP REST role

If the access token contains a named REST role in the `scope` or `scp` field, or as a claim, ONTAP uses the role to make the access decision. This always results in an **ALLOW** or **DENY** decision and processing ends.

If there is no named REST role or the role is not found, continue to step 4.

Step 4: Users

Extract the username from the access token and attempt to match it to users that have access to the application "http". The users are examined based on the authentication method in the following order:

- password
- domain (Active Directory)
- nsswitch (LDAP)

If a matching user is found, ONTAP uses the role defined for the user to make an access decision. This always result in an **ALLOW** or **DENY** decision and processing ends.

If a user is not matched or if there's no username in the access token, continue to step 5.

Step 5: Groups

If one or more groups are included, the format is examined. If the groups are represented as UUIDs, an internal group mapping table is searched. If there's a group match and an associated role, ONTAP uses the role defined for the group to make an access decision. This always result in an **ALLOW** or **DENY** decision and processing ends. For more information see Working with OAuth 2.0 or SAML IdP groups in ONTAP.

If groups are represented as names and configured with domain or nsswitch authorization, ONTAP attempts to match them to an Active Directory or LDAP group, respectively. If there's a group match, ONTAP uses the role defined for the group to make an access decision. This always result in an **ALLOW** or **DENY** decision and processing ends.

If there's no group match or if there's no group in the access token, access is denied and processing ends.

ONTAP 9.14.1

Initial OAuth 2.0 supported is introduced with ONTAP 9.14.1 based on the standard OAuth 2.0 features.

Determine client access for ONTAP 9.14.1

Step 1: Self-contained scopes

If the access token contains any self-contained scopes, ONTAP examines these scopes first. If there are no self-contained scopes, go to step 2.

With one or more self-contained scopes present, ONTAP applies each scope until an explicit **ALLOW** or **DENY** decision can be made. If an explicit decision is made, processing ends.

If ONTAP can’t make an explicit access decision, continue to step 2.

Step 2: Check the local roles flag

ONTAP examines the boolean parameter `use-local-roles-if-present`. The value of this flag is set separately for each authorization server defined to ONTAP.

- If the value is `true` continue to step 3.
- If the value is `false` processing ends and access is denied.

Step 3: Named ONTAP REST role

If the access token contains a named REST role in the `scope` or `scp` field, ONTAP uses the role to make the access decision. This always results in an **ALLOW** or **DENY** decision and processing ends.

If there is no named REST role or the role is not found, continue to step 4.

Step 4: Users

Extract the username from the access token and attempt to match it to users that have access to the application "http". The users are examined based on the authentication method in the following order:

- password
- domain (Active Directory)
- nsswitch (LDAP)

If a matching user is found, ONTAP uses the role defined for the user to make an access decision. This always result in an **ALLOW** or **DENY** decision and processing ends.

If a user is not matched or if there’s no username in the access token, continue to step 5.

Step 5: Groups

If one or more groups are included and configured with domain or nsswitch authorization, ONTAP attempts to match them to an Active Directory or LDAP group, respectively.

If there’s a group match, ONTAP uses the role defined for the group to make an access decision. This always result in an **ALLOW** or **DENY** decision and processing ends.

If there’s no group match or if there’s no group in the access token, access is denied and processing ends.

OAuth 2.0 deployment scenarios with ONTAP

There are several configuration options available when defining an authorization server to ONTAP. Based on these options, you can define an authorization server appropriate for your environment using one of several deployment scenarios.

Summary of the configuration parameters

There are several configuration parameters available when defining an authorization server to ONTAP. These parameters are generally supported in all the administrative interfaces.

> The name used for an individual parameter or field can vary depending on the ONTAP administrative interface. To accommodate the differences in the administrative interfaces, a single generic name is used for each parameter in the table. The exact name used with a specific interface should be obvious based on the context.

Parameter	Description
Name	The name of the authorization server as it is known to ONTAP.
Application	The ONTAP internal application the definition applies to. This must be **http**.
Issuer URI	The FQDN with path identifying the site or organization that issues the tokens.
Provider JWKS URI	The FQDN with path and file name where ONTAP obtains the JSON Web Key Sets used to validate the access tokens.
JWKS refresh interval	The time interval determining how often ONTAP refreshes certificate information from the provider JWKS URI. The value is specified in ISO-8601 format.
Introspection endpoint	The FQDN with path that ONTAP uses to perform remote token validation through introspection.
Client ID	The name of the client as defined at the authorization server. When this value is included, you also need to provide the associated client secret based on the interface.
Outgoing proxy	This is to provide access to the authorization server when ONTAP is behind a firewall. The URI must be in curl format.
Use local roles if present	A boolean flag determining if the local ONTAP definitions are used, including a named REST role and local users.
Remote user claim	An alternative name that ONTAP uses to match local users. Use the `sub` field in the access token to match the local username.
Audience	This field defines the endpoints where the access token can be used.

Deployment scenarios

Several common deployment scenarios are presented below. They are organized based on whether token validation is performed locally by ONTAP or remotely by the authorization server. Each scenario includes a list of the required configuration options. See Deploy OAuth 2.0 in ONTAP for examples of the configuration commands.

After defining an authorization server, you can display its configuration through the ONTAP administrative interface. For example, use the command `security oauth2 client show` with the ONTAP CLI.

Local validation

The following deployment scenarios are based on ONTAP performing token validation locally.

Use self-contained scopes without a proxy

This is the simplest deployment using only OAuth 2.0 self-contained scopes. None of the local ONTAP identity definitions are used. You need to include the following parameters:

- Name
- Application (http)
- Provider JWKS URI
- Issuer URI

You also need to add the scopes at the authorization server.

Use self-contained scopes with a proxy

This deployment scenario uses the OAuth 2.0 self-contained scopes. None of the local ONTAP identity definitions are used. But the authorization server is behind a firewall and so you need to configure a proxy. You need to include the following parameters:

- Name
- Application (http)
- Provider JWKS URI
- Outgoing proxy
- Issuer URI
- Audience

You also need to add the scopes at the authorization server.

Use local user roles and default username mapping with a proxy

This deployment scenario uses local user roles with default name mapping. The remote user claim uses the default value of `sub` and so this field in the access token is used to match the local username. The username must be 40 characters or less. The authorization server is behind a firewall so you also need to configure a proxy. You need to include the following parameters:

- Name
- Application (http)
- Provider JWKS URI
- Use local roles if present (`true`)
- Outgoing proxy
- Issuer

You need to make sure the local user is defined to ONTAP.

Use local user roles and alternate username mapping with a proxy

This deployment scenario uses local user roles with an alternate username which is used to match a local ONTAP user. The authorization server is behind a firewall, so you need to configure a proxy. You need to include the following parameters:

- Name
- Application (http)
- Provider JWKS URI
- Use local roles if present (`true`)
- Remote user claim
- Outgoing proxy
- Issuer URI
- Audience

You need to make sure the local user is defined to ONTAP.

Remote introspection

The following deployment configurations are based on ONTAP performing token validation remotely through introspection.

Use self-contained scopes with no proxy

This is a simple deployment based on using the OAuth 2.0 self-contained scopes. None of the ONTAP identity definitions are used. You must include the following parameters:

- Name
- Application (http)
- Introspection endpoint
- Client ID
- Issuer URI

You need to define the scopes as well as the client and client secret at the authorization server.

Related information

- security oauth2 client show

ONTAP client authentication using OAuth 2.0 Mutual TLS

Depending on your security needs, you can optionally configure Mutual TLS (mTLS) to implement strong client authentication. When used with ONTAP as part of an OAuth 2.0 deployment, mTLS guarantees the access tokens are only used by the clients to which they were originally issued.

Mutual TLS with OAuth 2.0

Transport Layer Security (TLS) is used to establish a secure communication channel between two applications, typically a client browser and web server. Mutual TLS extends this by providing strong identification of the client through a client certificate. When used in an ONTAP cluster with OAuth 2.0, the base mTLS functionality is extended by creating and using sender-constrained access tokens.

A sender-constrained access token can only be used by the client to which it was originally issued. To support this feature, a new confirmation claim (`cnf`) is inserted into the token. The field contains property `x5t#S256` which holds a digest of the client certificate used when requesting the access token. This value is verified by ONTAP as part of validating the token. Access tokens issued by authorization servers that are not sender-constrained do not include the additional confirmation claim.

You need to configure ONTAP to use mTLS separately for each authorization server. For example, the CLI command `security oauth2 client` includes the parameter `use-mutual-tls` to control mTLS processing based on three values as shown in the table below.

> ⓘ In each configuration, the outcome and action taken by ONTAP is dependent on the configuration parameter value as well as the contents of the access token and the client certificate. The parameters in the table are organized from the least to the most restrictive.

Parameter	Description
none	OAuth 2.0 mutual TLS authentication is completely disabled for the authorization server. ONTAP will not perform mTLS client certificate authentication even if the confirmation claim is present in the token or a client certificate is supplied with the TLS connection.
request	OAuth 2.0 mutual TLS authentication is enforced if a sender-constrained access token is presented by the client. That is, mTLS is enforced only if the confirmation claim (with property `x5t#S256`) is present in the access token. This is the default setting.
required	OAuth 2.0 mutual TLS authentication is enforced for all access tokens issued by the authorization server. Therefore, all access tokens must be sender-constrained. Authentication and the REST API request fail if the confirmation claim is not present in the access token or there is an invalid client certificate.

High-level implementation flow

The typical steps involved when using mTLS with OAuth 2.0 in an ONTAP environment are presented below. See RFC 8705: OAuth 2.0 Mutual-TLS Client Authentication and Certificate-Bound Access Tokens for more details.

Step 1: Create and install a client certificate

Establishing client identity is based on proving knowledge of a client private key. The corresponding public key is placed in a signed X.509 certificate presented by the client. At a high level, the steps involved in creating the client certificate include:

1. Generate a public and private key pair
2. Create a certificate signing request
3. Send the CSR file to a well-known CA
4. CA verifies the request and issues the signed certificate

You can normally install the client certificate in your local operating system or use it directly with a common utility such as curl.

Step 2: Configure ONTAP to use mTLS

You need to configure ONTAP to use mTLS. This configuration is done separately for each authorization server. For example, with the CLI the command `security oauth2 client` is used with the optional parameter `use-mutual-tls`. See Deploy OAuth 2.0 in ONTAP for more information.

Step 3: Client requests an access token

The client needs to request an access token from the authorization server configured to ONTAP. The client application must use mTLS with the certificate created and installed in step 1.

Step 4: Authorization server generates the access token

The authorization server verifies the client request and generates an access token. As part of this, it creates a message digest of the client certificate which is included in the token as a confirmation claim (field `cnf`).

Step 5: Client application presents the access token to ONTAP

The client application makes a REST API call to the ONTAP cluster and includes the access token in the authorization request header as a **bearer token**. The client must use mTLS with the same certificate used to request the access token.

Step 6: ONTAP verifies client and token.

ONTAP receives the access token in an HTTP request as well as the client certificate used as part of mTLS processing. ONTAP first validates the signature in the access token. Based on the configuration, ONTAP generates a message digest of the client certificate and compares it to the confirmation claim **cnf** in the token. If the two values match, ONTAP has confirmed the client making the API request is the same client the access token was originally issued to.

Configure and deploy

Prepare to deploy OAuth 2.0 with ONTAP

Before configuring OAuth 2.0 in an ONTAP environment, you should prepare for the deployment. A summary of the major tasks and decisions is included below. The arrangement of the sections is generally aligned with the order you should follow. But while it’s applicable for most deployments, you should adapt it to your environment as needed. You should also consider creating a formal deployment plan.

> Based on your environment, you can select the configuration for the authorization servers defined to ONTAP. This includes the parameter values you need to specific for each type of deployment. See OAuth 2.0 deployment scenarios for more information.

Protected resources and client applications

OAuth 2.0 is an authorization framework for controlling access to protected resources. Given this, an important first step with any deployment is to determine what the available resources are and which clients need access to them.

Identify client applications

You need to decide which clients will use OAuth 2.0 when issuing REST API calls and what API endpoints they need access to.

Review existing ONTAP REST roles and local users

You should review the existing ONTAP identity definitions, including the REST roles and local users. Depending on how you configure OAuth 2.0, these definitions can be used for making access decisions.

Global transition to OAuth 2.0

While you might implement OAuth 2.0 authorization gradually, you can also move all the REST API clients to OAuth 2.0 immediately by setting a global flag for each authorization server. This allows access decisions to be made based on your existing ONTAP configuration without the need for creating self-contained scopes.

Authorization servers

The authorization servers play an important role in your OAuth 2.0 deployment by issuing access tokens and enforcing administrative policy.

Select and install the authorization server

You need to select and install one or more authorization servers. It's important to become familiar with the configuration options and procedures of your identity providers, including how to define scopes. Note that some authorization servers, including Microsoft Entra ID, represent groups using UUIDs instead of names.

Determine if the authorization root CA certificate needs to be installed

ONTAP uses the authorization server's certificate to validate the signed access tokens presented by the clients. To do this, ONTAP needs the root CA certificate and any intermediate certificates. These might be pre-installed with ONTAP. If not, you need to install them.

Assess network location and configuration

If the authorization server is behind a firewall, ONTAP needs to be configured to use a proxy server.

Client authentication and authorization

There are several aspects of client authentication and authorization you need to consider.

Self-contained scopes or local ONTAP identity definitions

At a high level, you can either define self-contained scopes defined at the authorization server or rely on the existing local ONTAP identity definitions including roles and users.

Options with local ONTAP processing

If you use the ONTAP identity definitions, you must decide which to apply, including:

- Named REST role
- Match local users
- Active Directory or LDAP groups

Local validation or remote introspection

You need to decide if the access tokens will be validated locally by ONTAP or at the authorization server through introspection. There are also several related values to consider, such as the refresh interval.

Sender-constrained access tokens

For environments requiring a high level of security, you can use send-constrained access tokens based on mTLS. This requires a certificate for each client.

Groups as UUIDs and identity mapping

If you are using an authorization server that represents groups using UUIDs, you need to plan how to map these to group names and possibly to associated roles.

Administrative interface

You can perform administration of OAuth 2.0 through any of the ONTAP interfaces, including:

- Command line interface
- System Manager
- REST API

How clients request access tokens

The client applications must request access tokens directly from the authorization server. You need to decide how this will be done, including the grant type.

Configure ONTAP

There are several ONTAP configuration tasks you need to perform.

Define REST roles and local users

Based on your authorization configuration, local ONTAP identify processing can be used. In this case, you need to review and define the REST roles and user definitions. And depending on your authorization server, this might also include administering groups based on UUID values.

Core configuration

There are three major steps needed to perform the core ONTAP configuration, including:

- Optionally install the root certificate (and any intermediate certificates) for the CA that signed the authorization server's certificate.
- Define the authorization server.
- Enable OAuth 2.0 processing for the cluster.

Deploy OAuth 2.0 in ONTAP

Deploying the core OAuth 2.0 functionality involves three primary steps.

Before you begin

You must prepare for the OAuth 2.0 deployment before configuring ONTAP. For example, you need to assess the authorization server, including how its certificate was signed and if it's behind a firewall. See Prepare to deploy OAuth 2.0 with ONTAP for more information.

Step 1: Install the authorization server root CA certificates

ONTAP includes a large number of pre-installed root CA certificates. So in many cases, the certificate for your authorization server will be immediately recognized by ONTAP without additional configuration. But depending on how the authorization server certificate was signed, you may need to install a root CA certificate and any intermediate certificates.

Follow the instructions provided below to install the certificate if it's needed. You should install all the required certificates at the cluster level.

Choose the correct procedure based on how you access ONTAP.

Example 26. Steps

System Manager

1. In System Manager, select **Cluster** > **Settings**.
2. Scroll down to the **Security** section.
3. Click → next to **Certificates**.
4. Under the **Trusted certificate authorities** tab click **Add**.
5. Click **Import** and select the certificate file.
6. Complete the configuration parameters for your environment.
7. Click **Add**.

CLI

1. Begin the installation:

```
security certificate install -type server-ca
```

2. Look for the following console message:

```
Please enter Certificate: Press <Enter> when done
```

3. Open the certificate file with a text editor.
4. Copy the entire certificate including the following lines:

```
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----
```

5. Paste the certificate into the terminal after the command prompt.
6. Press **Enter** to complete the installation.
7. Confirm the certificate is installed using one of the following:

```
security certificate show-user-installed
```

```
security certificate show
```

Step 2: Configure the authorization server

You need to define at least one authorization server to ONTAP. You should choose the parameter values based on your configuration and deployment plan. Review OAuth2 deployment scenarios to determine the exact parameters needed for your configuration.

> To modify an authorization server definition, you can delete the existing definition and create a new one.

The example provided below is based on the first simple deployment scenario at Local validation. Self-contained scopes are used without a proxy.

Choose the correct procedure based on how you access ONTAP. The CLI procedure uses symbolic variables that you need to replace before issuing the command.

Example 27. Steps

System Manager

1. In System Manager, select **Cluster** > **Settings**.
2. Scroll down to the **Security** section.
3. Click **+** next to **OAuth 2.0 authorization**.
4. Select **More options**.
5. Provide the required values for your deployment, such as:
   - Name
   - Application (http)
   - Provider JWKS URI
   - Issuer URI
6. Click **Add**.

CLI

1. Create the definition again:

```
security oauth2 client create -config-name <NAME> -provider-jwks-uri
<URI_JWKS> -application http -issuer <URI_ISSUER>
```

For example:

```
security oauth2 client create \
-config-name auth0 \
-provider-jwks-uri https://superzap.dev.netapp.com:8443/realms/my-
realm/protocol/openid-connect/certs \
-application http \
-issuer https://superzap.dev.netapp.com:8443/realms/my-realm
```

Learn more about `security oauth2 client create` in the ONTAP command reference.

Step 3: Enable OAuth 2.0

The final step is to enable OAuth 2.0. This is a global setting for the ONTAP cluster.

> Don’t enable OAuth 2.0 processing until you confirm that ONTAP, the authorization servers, and any supporting services have all been properly configured.

Choose the correct procedure based on how you access ONTAP.

Example 28. Steps

System Manager

1. In System Manager, select **Cluster** > **Settings**.
2. Scroll down to the **Security section**.
3. Click → next to **OAuth 2.0 authorization**.
4. Enable **OAuth 2.0 authorization**.

CLI

1. Enable OAuth 2.0:

   ```
   security oauth2 modify -enabled true
   ```

2. Confirm OAuth 2.0 is enabled:

   ```
   security oauth2 show
   Is OAuth 2.0 Enabled: true
   ```

Related information

- security certificate show
- security oauth2 modify
- security oauth2 show

Issue an ONTAP REST API call using OAuth 2.0

The OAuth 2.0 implementation in ONTAP supports REST API client applications. You can issue a simple REST API call using curl to get started using OAuth 2.0. The example presented below retrieves the ONTAP cluster version.

Before you begin

You must configure and enable the OAuth 2.0 feature for your ONTAP cluster. This includes defining an authorization server.

Step 1: Acquire an access token

You need to acquire an access token to use with the REST API call. The token request is performed outside of ONTAP and the exact procedure depends on the authorization server and its configuration. You might request the token through a web browser, with a curl command, or using a programming language.

For illustration purposes, an example of how an access token can be requested from Keycloak using curl is presented below.

Keycloak example

```
curl --request POST \
--location
'https://superzap.dev.netapp.com:8443/realms/peterson/protocol/openid-
connect/token' \
--header 'Content-Type: application/x-www-form-urlencoded' \
--data-urlencode 'client_id=dp-client-1' \
--data-urlencode 'grant_type=client_credentials' \
--data-urlencode 'client_secret=5iTUf9QKLGxAoYa1iR33vlD5A2xq09V7'
```

You should copy and save the returned token.

Step 2: Issue the REST API call

After you have a valid access token, you can use a curl command with the access token to issue a REST API call.

Parameters and variables

The two variables in the curl example are described in the table below.

Variable	Description
$FQDN_IP	The fully qualified domain name or IP address of the ONTAP management LIF.
$ACCESS_TOKEN	The OAuth 2.0 access token issued by the authorization server.

You should first set these variables in the Bash shell environment before issuing the curl example. For example, in the Linux CLI type the following command to set and display the FQDN variable:

```
FQDN_IP=172.14.31.224
echo $FQDN_IP
172.14.31.224
```

After both variables are defined in your local Bash shell, you can copy the curl command and paste it into the CLI. Press **Enter** to substitute the variables and issue the command.

Curl example

```
curl --request GET \
--location "https://$FQDN_IP/api/cluster?fields=version" \
--include \
--header "Accept: */*" \
--header "Authorization: Bearer $ACCESS_TOKEN"
```

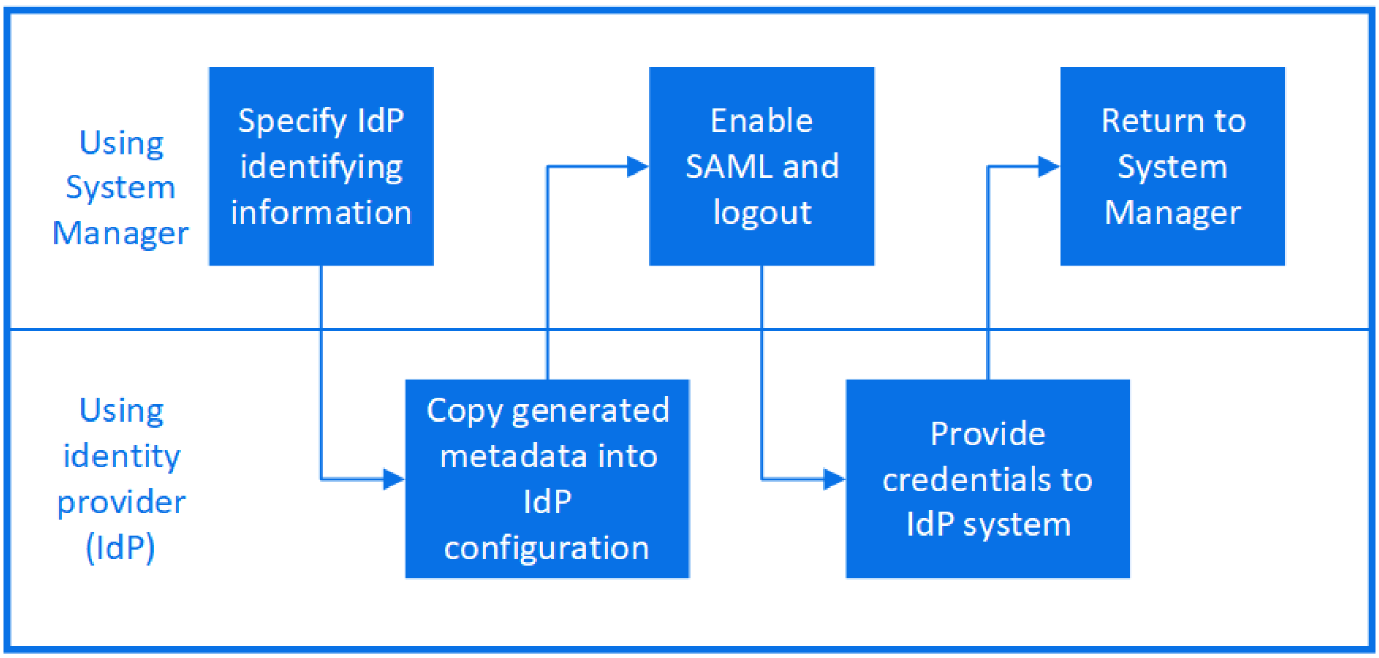
Configure SAML authentication for remote ONTAP users

Beginning with ONTAP 9.3, you can configure Security Assertion Markup Language (SAML) authentication for web services. When SAML authentication is configured and enabled, users are authenticated by an external Identity Provider (IdP) instead of the directory service providers such as Active Directory and LDAP. When SAML authentication is disabled, the configured directory service providers such as Active Directory and LDAP are used for authentication.

Enable SAML authentication

To enable SAML authentication with System Manager or with the CLI, perform the following steps. If your cluster is running ONTAP 9.7 or earlier, the System Manager steps you need to follow are different. Refer to the System Manager online help available on your system.

After you enable SAML authentication, only remote users configured for SAML authentication can access the System Manager GUI. Local users cannot access the System Manager GUI after SAML authentication is enabled.



About this task

- SAML authentication applies only to the ONTAP `http` and `ontapi` applications.

  The `http` and `ontapi` applications are used by the following web services: Service Processor Infrastructure, ONTAP APIs, and System Manager.

- SAML authentication is applicable only for accessing the admin SVM.
- Beginning with ONTAP 9.17.1, IdP-provided group information can be mapped to ONTAP roles. This allows you to assign roles to users based on groups that are defined in the IdP. For more information, see Working with OAuth 2.0 or SAML IdP groups in ONTAP.

The following IdPs have been validated with System Manager:

- Microsoft Entra ID (validated with ONTAP 9.17.1 and later)
- Active Directory Federation Services
- Cisco Duo (validated with the following ONTAP versions:)
  - 9.7P21 and later 9.7 releases (refer to the System Manager Classic documentation)
  - 9.8P17 and later 9.8 patch releases
  - 9.9.1P13 and later 9.9.1 patch releases
  - 9.10.1P9 and later 9.10.1 patch releases
  - 9.11.1P4 and later 9.11.1 patch releases
  - 9.12.1 and later releases
- Shibboleth

Before you begin

- The IdP that you plan to use for remote authentication must be configured. You must have the URI of the IdP. The IdP URI is the web address that ONTAP sends authentication requests to and receive responses from.
- Port 443 must be open between the ONTAP cluster and the IdP.
- The ONTAP cluster and the IdP must each be able to ping the other's fully qualified domain name. Ensure DNS is properly configured and the cluster certificate is not expired.
- If needed, add the IdP's trusted certificate authority (CA) to ONTAP. You can manage ONTAP certificates with System Manager. You might need to configure the ONTAP cluster certificate in the IdP.
- You must be able to access the ONTAP cluster's Service Processor (SP) console. If SAML is misconfigured, you will need to disable it from the SP console.
- If you are using Entra ID (validated beginning with ONTAP 9.17.1), you must configure Entra ID with the ONTAP metadata before creating the ONTAP SAML configuration. Entra ID will not provide the IdP URI until it is configured with the ONTAP metadata. The IdP URI is required to create the ONTAP SAML configuration.
  - If you are using System Manager to configure SAML, leave the IdP URI field blank until System Manager provides the ONTAP metadata. Configure Entra ID with the ONTAP metadata, and then copy the IdP URI into System Manager before enabling the SAML configuration.
  - If you are using the ONTAP CLI to configure SAML, you must generate the ONTAP metadata before enabling the ONTAP SAML configuration. You can generate the ONTAP metadata file with the following command:

    ```
    security saml-sp default-metadata create -sp-host <ontap_host_name>
    ```

    `ontap_host_name` is the host name or IP address of the SAML service provider host, which in this case is the ONTAP system. By default, the cluster-management IP address is used. You can optionally provide the ONTAP server certificate information. By default, the ONTAP web server certificate information is used.

    Configure Entra ID with the provided metadata. You must configure Entra ID before creating the ONTAP SAML configuration. After Entra is configured, proceed with the below CLI procedure.
  - You cannot generate the ONTAP metadata for Entra ID until all nodes in the cluster are on version 9.17.1.

Steps

Perform the following steps depending on your environment:

System Manager

1. Click **Cluster > Settings**.
2. Next to **SAML Authentication**, click ⚙.
3. Ensure there is a check in the **Enable SAML Authentication** checkbox.
4. Enter the URL of the IdP URI (including "https://"). If you are using Entra ID, skip this step.
5. Modify the host system address, if needed. This is the address that the IdP will direct to after authentication. The default is the cluster-management IP address.
6. Ensure the correct certificate is being used:
   - If your system was mapped with only one certificate with type "server", then that certificate is considered the default and it isn't displayed.
   - If your system was mapped with multiple certificates as type "server", then one of the certificates is displayed. To select a different certificate, click **Change**.
7. Click **Save**. A confirmation window displays the metadata information, which has been automatically copied to your clipboard.
8. Go to the IdP system you specified and copy the metadata from your clipboard to update the system metadata. If you are using Entra ID, copy the IdP URI into ONTAP after you have configured Entra ID with the system metadata.
9. Return to the confirmation window (in System Manager) and check the checkbox **I have configured the IdP with the host URI or metadata**.
10. Click **Logout** to enable SAML-based authentication. The IdP system will display an authentication screen.
11. In the IdP sign-on page, enter your SAML-based credentials. After your credentials are verified, you will be directed to the System Manager home page.

CLI

1. Create a SAML configuration so that ONTAP can access the IdP metadata:

   ```
   security saml-sp create -idp-uri <idp_uri> -sp-host <ontap_host_name>
   ```

   `idp_uri` is the FTP or HTTP address of the IdP host from where the IdP metadata can be downloaded.

   > ⓘ Some URLs include the question mark (?) character. The question mark activates the ONTAP command line active help. In order to enter a URL with a question mark, you need to first disable active help with the command `set -active-help false`. Active help can later be re-enabled with the command `set -active-help true`. Learn more in the ONTAP command reference.

   `ontap_host_name` is the host name or IP address of the SAML service provider host, which in this case is the ONTAP system. By default, the IP address of the cluster-management LIF is used.

   You can optionally provide the ONTAP server certificate information. By default, the ONTAP web server certificate information is used.

```
cluster_12::> security saml-sp create -idp-uri
https://example.url.net/idp/shibboleth

Warning: This restarts the web server. Any HTTP/S connections that
are active
         will be disrupted.
Do you want to continue? {y|n}: y
[Job 179] Job succeeded: Access the SAML SP metadata using the URL:
https://10.0.0.1/saml-sp/Metadata

Configure the IdP and ONTAP users for the same directory server
domain to ensure that users are the same for different
authentication methods. See the "security login show" command for
the ONTAP user configuration.
```

The URL to access the ONTAP host metadata is displayed.

2. From the IdP host, configure the IdP with the ONTAP host metadata. If you are using Entra ID, you have already completed this step.
3. Once the IdP is configured, enable SAML configuration:

   ```
   security saml-sp modify -is-enabled true
   ```

   Any existing user that accesses the `http` or `ontapi` application is automatically configured for SAML authentication.

4. If you want to create users for the `http` or `ontapi` application after SAML is configured, specify SAML as the authentication method for the new users. Prior to ONTAP 9.17.1, a SAML login is automatically created for existing `http` or `ontapi` users when SAML is enabled. New users must be configured for SAML. Beginning with ONTAP 9.17.1, all users created with `password`, `domain`, or `nsswitch` authentication methods are automatically authenticated against the IdP when SAML is enabled.

   a. Create a login method for new users with SAML authentication. The `user_name` must match the username configured in the IdP:

      The `user_name` value is case-sensitive. Include only the user name, and do not include any portion of the domain.

      ```
      security login create -user-or-group-name <user_name> -application [http
      | ontapi] -authentication-method saml -vserver <svm_name>
      ```

      Example:

      ```
      cluster_12::> security login create -user-or-group-name admin1
      -application http -authentication-method saml -vserver cluster_12
      ```

b. Verify that the user entry is created:

`security login show`

Example:

```
cluster_12::> security login show

Vserver: cluster_12

none
```

Learn more about `security login show` in the ONTAP command reference.

Disable SAML authentication

You can disable SAML authentication when you want to stop authenticating remote System Manager users with an external Identity Provider (IdP). When SAML authentication is disabled, local user authentication or the configured directory service providers such as Active Directory and LDAP are used to authenticate users.

Perform the following steps depending on your environment:

Example 29. Steps

System Manager

1. Click **Cluster > Settings**.
2. Under **SAML Authentication**, click the **Enabled** toggle button.
3. *Optional*: You can also click ⚙ next to **SAML Authentication**, and then uncheck the **Enable SAML Authentication** checkbox.

CLI

1. Disable SAML authentication:

```
security saml-sp modify -is-enabled false
```

2. If you no longer want to use SAML authentication or if you want to modify the IdP, delete the SAML configuration:

```
security saml-sp delete
```

Configure third-party IdP

About this task

In order to authenticate with ONTAP, you might need to change the settings for your IdP. The following sections provide configuration information for supported IdPs.

Entra ID

When configuring Entra ID, create a new application and configure SAML sign-on with the metadata provided by ONTAP. After the application is created, edit the "Attributes & Claims" section of the application SAML settings to match the following:

Setting	Value
Name	urn:oid:0.9.2342.19200300.100.1.1
Namespace	*Leave blank*
Name format	URI
Source	Attribute
Source attribute	user.userprincipalname

If you want to use groups with Entra ID, add a group claim with the following settings:

Setting	Value
Name	urn:oid:1.3.6.1.4.1.5923.1.5.1.1
Namespace	*Leave blank*
Source attribute	Group ID

Entra ID provides group information in UUID format. For more information on using groups with Entra ID, refer to Manage groups with UUIDs.

The *App Federation Metadata URL* provided in the "SAML certificate" section of the application SAML settings is the IdP URI that you will enter in ONTAP.

For information on configuring Entra ID multifactor authentication, refer to Plan a Microsoft Entra multifactor authentication deployment.

For more information, refer to the Entra ID documentation.

Active Directory Federation Services

When configuring Active Directory Federation Services (AD FS), you must add a new claims-aware Relying Party Trust with the service provider metadata provided by ONTAP. Once the Relying Party Trust is created, add the following claim rules to the Relying Party Trust's Claim Issuance Policy using the "Send LDAP Attributes as Claims" template:

Attribute store	LDAP attribute	Outgoing claim type
Active Directory	SAM-account-name	Name ID
Active Directory	SAM-account-name	urn:oid:0.9.2342.19200300.100.1.1
Active Directory	Name Format	urn:oasis:names:tc:SAML:2.0:attrname-format:uri
Active Directory	Token groups - Qualified by Domain Name	urn:oid:1.3.6.1.4.1.5923.1.5.1.1
Active Directory	sAMAccountName	urn:oid:1.2.840.113556.1.4.221

AD FS provides group information in name format. For more information on using groups with AD FS, refer to Manage groups with names.

For more information, refer to the AD FS documentation.

Cisco Duo

Refer to the Cisco Duo documentation for configuration information.

Shibboleth

Prior to configuring the Shibboleth IdP, you must have configured an LDAP server.

When enabling SAML on ONTAP, save the provided host metadata XML. On the host where Shibboleth is installed, replace the contents of `metadata/sp-metadata.xml` with the host metadata XML within the Shibboleth IdP home directory.

For more information, refer to Shibboleth.

Troubleshoot issues with SAML configuration

If configuring Security Assertion Markup Language (SAML) authentication fails, you can manually repair each node on which the SAML configuration failed and recover from the failure. During the repair process, the web server is restarted and any active HTTP connections or HTTPS connections are disrupted.

About this task

When you configure SAML authentication, ONTAP applies SAML configuration on a per-node basis. When you enable SAML authentication, ONTAP automatically tries to repair each node if there are configuration issues. If there are issues with SAML configuration on any node, you can disable SAML authentication and then reenable SAML authentication. There can be situations when SAML configuration fails to apply on one or more nodes even after you reenable SAML authentication. You can identify the node on which SAML configuration has failed and then manually repair that node.

Steps

1. Log in to the advanced privilege level:

   ```
   set -privilege advanced
   ```

2. Identify the node on which SAML configuration failed:

   ```
   security saml-sp status show -instance
   ```

   Example:

```
cluster_12::*> security saml-sp status show -instance

                         Node: node1
                Update Status: config-success
               Database Epoch: 9
   Database Transaction Count: 997
                   Error Text:
SAML Service Provider Enabled: false
        ID of SAML Config Job: 179

                         Node: node2
                Update Status: config-failed
               Database Epoch: 9
   Database Transaction Count: 997
                   Error Text: SAML job failed, Reason: Internal error.
Failed to receive the SAML IDP Metadata file.
SAML Service Provider Enabled: false
        ID of SAML Config Job: 180
2 entries were displayed.
```

Learn more about `security saml-sp status show` in the ONTAP command reference.

3. Repair the SAML configuration on the failed node:

   `security saml-sp repair -node <node_name>`

   Example:

```
cluster_12::*> security saml-sp repair -node node2

Warning: This restarts the web server. Any HTTP/S connections that are
active
         will be disrupted.
Do you want to continue? {y|n}: y
[Job 181] Job is running.
[Job 181] Job success.
```

   The web server is restarted and any active HTTP connections or HTTPS connections are disrupted.

   Learn more about `security saml-sp repair` in the ONTAP command reference.

4. Verify that SAML is successfully configured on all of the nodes:

   `security saml-sp status show -instance`

   Example:

```
cluster_12::*> security saml-sp status show -instance

                         Node: node1
                Update Status: config-success
               Database Epoch: 9
   Database Transaction Count: 997
                   Error Text:
SAML Service Provider Enabled: false
        ID of SAML Config Job: 179

                         Node: node2
                Update Status: config-success
               Database Epoch: 9
   Database Transaction Count: 997
                   Error Text:
SAML Service Provider Enabled: false
        ID of SAML Config Job: 180
2 entries were displayed.
```

Learn more about `security saml-sp status show` in the ONTAP command reference.

Working with OAuth 2.0 or SAML IdP groups in ONTAP

ONTAP provides several options for configuring groups based on your OAuth 2.0 authorization server or SAML identity provider (IdP). The groups can then be mapped to roles which are used by ONTAP to determine access.

Beginning with ONTAP 9.17.1, SAML IdP-provided group information can be mapped to ONTAP roles. This allows you to assign roles to users based on the groups that are defined in the IdP. For more information, see Configure SAML authentication. Beginning with ONTAP 9.14.1, ONTAP supports group name authentication for OAuth 2.0. Beginning with ONTAP 9.16.1, ONTAP supports OAuth 2.0 group UUID authentication and role mapping. For more information, see Overview of the ONTAP OAuth 2.0 implementation.

How groups are identified

When you configure a group at an authorization server or SAML IdP, it's identified and carried in an OAuth 2.0 access token or SAML assertion using either a name or UUID. You need to be aware of how your authorization server or SAML IdP handles groups before configuring ONTAP.

> If multiple groups are included in an access token, ONTAP will attempt to use each one until there is a match.

Group names

Many authorization servers and SAML IdPs, like Active Directory Federation Service (ADFS), identify and represent groups using a name. Here's a fragment of a JSON OAuth 2.0 access token generated by ADFS containing several groups. See Manage groups with names for more information.

```
...
"sub": "User1_TestDev@NICAD5.COM",
"group": [
  "NICAD5\\Domain Users",
  "NICAD5\\Development Group",
  "NICAD5\\Production Group"
],
"apptype": "Confidential",
"appid": "3bff3b2b-8e40-44ba-7c11-d73c3b76e3e8",
...
```

Group UUIDs

Some authorization servers and SAML IdPs, like Microsoft Entra ID, identify and represent groups using a UUID. Here's a fragment of an OAuth 2.0 access token generated by Entra ID containing several groups. See Manage groups with UUIDs for more information.

```
...
"appid": "4aff4b4b-8e40-44ba-7c11-d73c3b76e3d7",
"appidacr": "1",
"groups": [
  "8ea4c5b0-bcad-4e66-8f1e-cd395474a448",
  "a8558fc2-a1b2-4cb7-cc41-59bd831840cc"],
"name": "admin007 with group membership",
...
```

Manage groups with names

If your authorization server or SAML IdP uses names to identify groups, you need to make sure each group is defined for your ONTAP cluster. Depending on your security environment, you might already have the group defined.

Here's an example CLI command defining an ONTAP group. Notice it uses a named group from the sample access token. You need to be at the ONTAP **admin** privilege level to issue the command.

Example

```
security login create -user-or-group-name "NICAD5\\Domain Users"
-application http -authentication-method domain -role admin
```

Use `-authentication-method domain` or `nsswitch` for SAML IdP and OAuth 2.0 authorization server groups.

> You can also configure this feature using the ONTAP REST API. Learn more in the ONTAP automation documentation.

Manage groups with UUIDs

If your authorization server or SAML IdP represents groups using UUID values, you need to perform a two-step configuration before using a group. Beginning with ONTAP 9.16.1, two mapping features are available and have been tested with Entra ID. Entra ID for OAuth 2.0 is supported beginning with ONTAP 9.16.1, and Entra ID for SAML is supported beginning with ONTAP 9.17.1. You need to be at the ONTAP **admin** privilege level to issue the CLI commands.

> You can also configure these features using the ONTAP REST API. Learn more in the ONTAP automation documentation.

Map a group UUID to a group name

If you're using an authorization server or SAML IdP that represents groups using UUID values, you need to map the group UUIDs to group names. The primary ONTAP CLI operations are described below.

Create

You can define a new group mapping configuration with the `security login group create` command. The group UUID and name should match the configuration at the authorization server or SAML IdP. Learn more about `security login group create` in the ONTAP command reference.

Parameters

The parameters used to create a group mapping are described below.

Parameter	Description
`vserver`	Optionally specifies the name of the SVM (vserver) the group is associated with. If omitted, the group is associated with the ONTAP cluster.
`name`	The unique name of the group that ONTAP will use.
`type`	This value indicates the identity provider the group originates from.
`uuid`	Specifies the universally unique identifier of the group as provided by the authorization server or SAML IdP.

Here's an example CLI command defining a group for ONTAP. Notice it uses a UUID group from the sample access token.

Example

```
security login group create -vserver ontap-cls-1 -name IAM_Dev -type entra
-uuid 8ea4c5b0-bcad-4e66-8f1e-cd395474a448
```

After creating the group, a unique read-only integer identifier is generated for the group.

Additional CLI operations

The command supports several additional operations, including:

- Show
- Modify
- Delete

You can use the `show` option to retrieve the unique group ID generated for a group. Learn more about `show` in the ONTAP command reference.

Map a group UUID to a role

If you're using an authorization server or SAML IdP that represents groups using UUID values, you can map the group to a role. For more information on Role-Based Access Control in ONTAP, refer to Learn about managing ONTAP access-control roles. The primary ONTAP CLI operations are described below. You need to be at the ONTAP **admin** privilege level to issue the commands.

> You need to first map a group UUID to a group name and retrieve the unique integer ID generated for the group. You'll need the ID to map the group to a role.

Create

You can define a new role mapping with the `security login group role-mapping create` command. Learn more about `security login group role-mapping create` in the ONTAP command reference.

Parameters

The parameters used to map a group to a role are described below.

Parameter	Description
`group-id`	Specifies the unique ID generated for the group using the command `security login group create`.
`role`	The name of the ONTAP role the group is mapped to.

Example

```
security login group role-mapping create -group-id 1 -role admin
```

Additional CLI operations

The command supports several additional operations, including:

- Show
- Modify
- Delete

Learn more about the commands described in this procedure in the ONTAP command reference.

Authentication and authorization using WebAuthn MFA

Learn about WebAuthn multi-factor authentication for ONTAP System Manager users

Beginning with ONTAP 9.16.1, administrators can enable WebAuthn multi-factor authentication (MFA) for users that log in to System Manager. This enables System Manager logins using a FIDO2 key (such as a YubiKey) as a second form of authentication. By default, WebAuthn MFA is disabled for new and existing ONTAP users.

WebAuthn MFA is supported for users and groups that use the following types of authentication for the first authentication method:

- Users: password, domain, or nsswitch
- Groups: domain or nsswitch

After you enable WebAuthn MFA as the second authentication method for a user, the user is asked to register a hardware authenticator upon logging in to System Manager. After registration, the private key is stored in the authenticator, and the public key is stored in ONTAP.

ONTAP supports one WebAuthn credential per user. If a user loses an authenticator and needs to have it replaced, the ONTAP administrator needs to delete the WebAuthn credential for the user so that the user can register a new authenticator upon the next login.

> Users that have WebAuthn MFA enabled as a second authentication method need to use the FQDN (for example, "https://myontap.example.com") instead of the IP address (for example, "https://192.168.100.200") to access System Manager. For users with WebAuthn MFA enabled, attempts to log in to the System Manager using the IP address are rejected.

Enable WebAuthn MFA for ONTAP System Manager users or groups

As an ONTAP administrator, you can enable WebAuthn MFA for a System Manager user or group by either adding a new user or group with the WebAuthn MFA option enabled or enabling the option for an existing user or group.

> After you enable WebAuthn MFA as the second authentication method for a user or group, the user (or all users in that group) will be asked to register a hardware FIDO2 device upon the next login to System Manager. This registration is handled by the user's local operating system, and usually consists of inserting the security key, creating a passkey, and touching the security key (if supported).

Enable WebAuthn MFA when creating a new user or group

You can create a new user or group with WebAuthn MFA enabled using either System Manager or the ONTAP CLI.

System Manager

1. Select **Cluster > Settings**.
2. Select the arrow icon next to **Users and Roles**.
3. Select **Add** under **Users**.
4. Specify a user or group name and select a role in the drop-down menu for **Role**.
5. Specify a login method and password for the user or group.

   WebAuthn MFA supports login methods of "password", "domain", or "nsswitch" for users, and "domain" or "nsswitch" for groups.

6. In the **MFA for HTTP** column, select **Enabled**.
7. Select **Save**.

CLI

1. Create a new user or group with WebAuthn MFA enabled.

   In the following example, WebAuthn MFA is enabled by choosing "publickey" for the second authentication method:

   ```
   security login create -user-or-group-name <user_or_group_name> \
                         -authentication-method domain \
                         -second-authentication-method publickey \
                         -application http \
                         -role admin
   ```

   Learn more about `security login create` in the ONTAP command reference.

Enable WebAuthn MFA for an existing user or group

You can enable WebAuthn MFA for an existing user or group.

System Manager

1. Select **Cluster > Settings**.
2. Select the arrow icon next to **Users and Roles**.
3. In the list of users and groups, select the option menu for the user or group you want to edit.

   WebAuthn MFA supports login methods of "password", "domain", or "nsswitch" for users, and "domain" or "nsswitch" for groups.

4. In the **MFA for HTTP** column for that user, select **Enabled**.
5. Select **Save**.

CLI

1. Modify an existing user or group to enable WebAuthn MFA for that user or group.

   In the following example, WebAuthn MFA is enabled by choosing "publickey" for the second authentication method:

   ```
   security login modify -user-or-group-name <user_or_group_name> \
                        -authentication-method domain \
                        -second-authentication-method publickey \
                        -application http \
                        -role admin
   ```

   Learn more about `security login modify` in the ONTAP command reference.

Disable WebAuthn MFA for ONTAP System Manager users

As an ONTAP administrator, you can disable WebAuthn MFA for a user or group by editing the user or group with System Manager or the ONTAP CLI.

Disable WebAuthn MFA for an existing user or group

You can disable WebAuthn MFA for an existing user or group at any time.

> If you disable registered credentials, the credentials are retained. If you enable the credentials again in the future, the same credentials are used, so the user doesn't need to re-register upon logging in.

System Manager

1. Select **Cluster > Settings**.
2. Select the arrow icon next to **Users and Roles**.
3. In the list of users and groups, select the user or group you want to edit.
4. In the **MFA for HTTP** column for that user, select **Disabled**.
5. Select **Save**.

CLI

1. Modify an existing user or group to disable WebAuthn MFA for that user or group.

   In the following example, WebAuthn MFA is disabled by choosing "none" for the second authentication method.

   ```
   security login modify -user-or-group-name <user_or_group_name> \
                        -authentication-method domain \
                        -second-authentication-method none \
                        -application http \
                        -role admin
   ```

   Learn more about `security login modify` in the ONTAP command reference.

View ONTAP WebAuthn MFA settings and manage credentials

As an ONTAP administrator, you can view cluster-wide WebAuthn MFA settings and manage user and group credentials for WebAuthn MFA.

View cluster settings for WebAuthn MFA

You can view the cluster settings for WebAuthn MFA using the ONTAP CLI.

Steps

1. View the cluster settings for WebAuthn MFA. You can optionally specify a storage VM using the `vserver` argument:

   ```
   security webauthn show -vserver <storage_vm_name>
   ```

   Learn more about `security webauthn show` in the ONTAP command reference.

View supported public key WebAuthn MFA algorithms

You can view the supported public key algorithms for WebAuthn MFA for a storage VM or for a cluster.

Steps

1. List the supported public key WebAuthn MFA algorithms. You can optionally specify a storage VM using the `vserver` argument:

```
security webauthn supported-algorithms show -vserver <storage_vm_name>
```

Learn more about `security webauthn supported-algorithms show` in the ONTAP command reference.

View the registered WebAuthn MFA credentials

As an ONTAP administrator, you can view the registered WebAuthn credentials for all users. Non-administrator users that use this procedure can only view their own registered WebAuthn credentials.

Steps

1. View the registered WebAuthn MFA credentials:

```
security webauthn credentials show
```

Learn more about `security webauthn credentials show` in the ONTAP command reference.

Remove a registered WebAuthn MFA credential

You can remove a registered WebAuthn MFA credential. This is useful when a user's hardware key was lost, stolen, or is no longer in use. You can also remove a registered credential when the user still has the original hardware authenticator, but wants to replace it with a new one. After removing the credential, the user will be prompted to register the replacement authenticator.

> Removing a registered credential for a user doesn't disable WebAuthn MFA for the user. If a user loses a hardware authenticator and needs to log in before replacing it, you need to remove the credential using these steps and also Disable WebAuthn MFA for the user.

System Manager

1. Select **Cluster > Settings**.
2. Select the arrow icon next to **Users and Roles**.
3. In the list of users and groups, select the option menu for the user or group whose credentials you want to remove.
4. Select **Remove MFA for HTTP credentials**.
5. Select **Remove**.

CLI

1. Delete the registered credentials. Note the following:
   - You can optionally specify a storage VM of the user. If omitted, the credential is removed at the cluster level.
   - You can optionally specify a username of the user for whom you are deleting the credential. If omitted, the credential is removed for the current user.

   ```
   security webauthn credentials delete -vserver <storage_vm_name>
   -username <username>
   ```

   Learn more about `security webauthn credentials delete` in the ONTAP command reference.

Manage web services

Manage web services overview

You can enable or disable a web service for the cluster or a storage virtual machine (SVM), display the settings for web services, and control whether users of a role can access a web service.

You can manage web services for the cluster or an SVM in the following ways:

- Enabling or disabling a specific web service
- Specifying whether access to a web service is restricted to only encrypted HTTP (SSL)
- Displaying the availability of web services
- Allowing or disallowing users of a role to access a web service
- Displaying the roles that are permitted to access a web service

For a user to access a web service, all of the following conditions must be met:

- The user must be authenticated.

  For instance, a web service might prompt for a user name and password. The user’s response must match a valid account.

* The user must be set up with the correct access method.

  Authentication only succeeds for users with the correct access method for the given web service. For the ONTAP API web service (`ontapi`), users must have the `ontapi` access method. For all other web services, users must have the `http` access method.

  > You use the `security login` commands to manage users' access methods and authentication methods.

* The web service must be configured to allow the user's access-control role.

  > You use the `vserver services web access` commands to control a role's access to a web service.

If a firewall is enabled, the firewall policy for the LIF to be used for web services must be set up to allow HTTP or HTTPS.

If you use HTTPS for web service access, SSL for the cluster or SVM that offers the web service must also be enabled, and you must provide a digital certificate for the cluster or SVM.

Manage access to ONTAP web services

A web service is an application that users can access by using HTTP or HTTPS. The cluster administrator can set up the web protocol engine, configure SSL, enable a web service, and enable users of a role to access a web service.

Beginning with ONTAP 9.6, the following web services are supported:

* Service Processor Infrastructure (`spi`)

  This service makes a node's log, core dump, and MIB files available for HTTP or HTTPS access through the cluster management LIF or a node management LIF. The default setting is `enabled`.

  Upon a request to access a node's log files or core dump files, the `spi` web service automatically creates a mount point from a node to another node's root volume where the files reside. You do not need to manually create the mount point.

* ONTAP APIs (`ontapi`)

  This service enables you to run ONTAP APIs to execute administrative functions with a remote program. The default setting is `enabled`.

  This service might be required for some external management tools. For example, if you use System Manager, you should leave this service enabled.

* Data ONTAP Discovery (`disco`)

  This service enables off-box management applications to discover the cluster in the network. The default setting is `enabled`.

* Support Diagnostics (`supdiag`)

This service controls access to a privileged environment on the system to assist problem analysis and resolution. The default setting is `disabled`. You should enable this service only when directed by technical support.

- System Manager (`sysmgr`)

  This service controls the availability of System Manager, which is included with ONTAP. The default setting is `enabled`. This service is supported only on the cluster.

- Firmware Baseboard Management Controller (BMC) Update (`FW_BMC`)

  This service enables you to download BMC firmware files. The default setting is `enabled`.

- ONTAP Documentation (`docs`)

  This service provides access to the ONTAP documentation. The default setting is `enabled`.

- ONTAP RESTful APIs (`docs_api`)

  This service provides access to the ONTAP RESTful API documentation. The default setting is `enabled`.

- File Upload and Download (`fud`)

  This service offers file upload and download. The default setting is `enabled`.

- ONTAP Messaging (`ontapmsg`)

  This service supports a publish and subscribe interface allowing you to subscribe to events. The default setting is `enabled`.

- ONTAP Portal (`portal`)

  This service implements the gateway into a virtual server. The default setting is `enabled`.

- ONTAP Restful Interface (`rest`)

  This service supports a RESTful interface that is used to remotely manage all elements of the cluster infrastructure. The default setting is `enabled`.

- Security Assertion Markup Language (SAML) Service Provider Support (`saml`)

  This service provides resources to support the SAML service provider. The default setting is `enabled`.

- SAML Service Provider (`saml-sp`)

  This service offers services such as SP metadata and the assertion consumer service to the service provider. The default setting is `enabled`.

Beginning with ONTAP 9.7, the following additional services are supported:

- Configuration Backup Files (`backups`)

This service enables you to download configuration backup files. The default setting is `enabled`.

- ONTAP Security (`security`)

  This service supports CSRF token management for enhanced authentication. The default setting is `enabled`.

Manage the web protocol engine in ONTAP

You can configure the web protocol engine on the cluster to control whether web access is allowed and what SSL versions can be used. You can also display the configuration settings for the web protocol engine.

You can manage the web protocol engine at the cluster level in the following ways:

- You can specify whether remote clients can use HTTP or HTTPS to access web service content by using the `system services web modify` command with the `-external` parameter.
- You can specify whether SSLv3 should be used for secure web access by using the `security config modify` command with the `-supported-protocol` parameter.
  By default, SSLv3 is disabled. Transport Layer Security 1.0 (TLSv1.0) is enabled and it can be disabled if needed.

  Learn more about `security config modify` in the ONTAP command reference.

- You can enable Federal Information Processing Standard (FIPS) 140-2 compliance mode for cluster-wide control plane web service interfaces.

  > By default, FIPS 140-2 compliance mode is disabled.

  - **When FIPS 140-2 compliance mode is disabled**
    You can enable FIPS 140-2 compliance mode by setting the `is-fips-enabled` parameter to `true` for the `security config modify` command, and then using the `security config show` command to confirm the online status.
  - **When FIPS 140-2 compliance mode is enabled**
    - Beginning with ONTAP 9.11.1, TLSv1, TLSv1.1 and SSLv3 are disabled, and only TSLv1.2 and TSLv1.3 remain enabled. It affects other systems and communications that are internal and external to ONTAP 9. If you enable FIPS 140-2 compliance mode and then subsequently disable, TLSv1, TLSv1.1, and SSLv3 remain disabled. Either TLSv1.2 or TLSv1.3 will remain enabled depending on the previous configuration.
    - For versions of ONTAP prior to 9.11.1, both TLSv1 and SSLv3 are disabled and only TLSv1.1 and TLSv1.2 remain enabled. ONTAP prevents you from enabling both TLSv1 and SSLv3 when FIPS 140-2 compliance mode is enabled. If you enable FIPS 140-2 compliance mode and then subsequently disable it, TLSv1 and SSLv3 remain disabled, but either TLSv1.2 or both TLSv1.1 and TLSv1.2 are enabled depending on the previous configuration.
- You can display the configuration of cluster-wide security by using the `system security config show` command.

  Learn more about `security config show` in the ONTAP command reference.

If the firewall is enabled, the firewall policy for the logical interface (LIF) to be used for web services must be set up to allow HTTP or HTTPS access.

If you use HTTPS for web service access, SSL for the cluster or storage virtual machine (SVM) that offers the web service must also be enabled, and you must provide a digital certificate for the cluster or SVM.

In MetroCluster configurations, the setting changes you make for the web protocol engine on a cluster are not replicated on the partner cluster.

ONTAP commands for managing the web protocol engine

You use the `system services web` commands to manage the web protocol engine. You use the `system services firewall policy create` and `network interface modify` commands to allow web access requests to go through the firewall.

If you want to…	Use this command…
Configure the web protocol engine at the cluster level: • Enable or disable the web protocol engine for the cluster • Enable or disable SSLv3 for the cluster • Enable or disable FIPS 140-2 compliance for secure web services (HTTPS)	`system services web modify`
Display the configuration of the web protocol engine at the cluster level, determine whether the web protocols are functional throughout the cluster, and display whether FIPS 140-2 compliance is enabled and online	`system services web show`
Display the configuration of the web protocol engine at the node level and the activity of web service handling for the nodes in the cluster	`system services web node show`
Create a firewall policy or add HTTP or HTTPS protocol service to an existing firewall policy to allow web access requests to go through firewall	`system services firewall policy create` Setting the `-service` parameter to `http` or `https` enables web access requests to go through firewall.
Associate a firewall policy with a LIF	`network interface modify` You can use the `-firewall-policy` parameter to modify the firewall policy of a LIF.

Related information

- network interface modify

Configure access to ONTAP web services

Configuring access to web services allows authorized users to use HTTP or HTTPS to access the service content on the cluster or a storage virtual machine (SVM).

Steps

1. If a firewall is enabled, ensure that HTTP or HTTPS access is set up in the firewall policy for the LIF that will be used for web services:

   > ⓘ You can check whether a firewall is enabled by using the `system services firewall show` command.

   a. To verify that HTTP or HTTPS is set up in the firewall policy, use the `system services firewall policy show` command.

      You set the `-service` parameter of the `system services firewall policy create` command to `http` or `https` to enable the policy to support web access.

   b. To verify that the firewall policy supporting HTTP or HTTPS is associated with the LIF that provides web services, use the `network interface show` command with the `-firewall-policy` parameter.

      Learn more about `network interface show` in the ONTAP command reference.

      You use the `network interface modify` command with the `-firewall-policy` parameter to put the firewall policy into effect for a LIF.

      Learn more about `network interface modify` in the ONTAP command reference.

2. To configure the cluster-level web protocol engine and make web service content accessible, use the `system services web modify` command.
3. If you plan to use secure web services (HTTPS), enable SSL and provide digital certificate information for the cluster or SVM by using the `security ssl modify` command.

   Learn more about `security ssl modify` in the ONTAP command reference.

4. To enable a web service for the cluster or SVM, use the `vserver services web modify` command.

   You must repeat this step for each service that you want to enable for the cluster or SVM.

5. To authorize a role to access web services on the cluster or SVM, use the `vserver services web access create` command.

   The role that you grant access must already exist. You can display existing roles by using the `security login role show` command or create new roles by using the `security login role create` command.

   Learn more about `security login role show` and `security login role create` in the ONTAP command reference.

6. For a role that has been authorized to access a web service, ensure that its users are also configured with the correct access method by checking the output of the `security login show` command.

To access the ONTAP API web service (`ontapi`), a user must be configured with the `ontapi` access method. To access all other web services, a user must be configured with the `http` access method.

Learn more about `security login show` in the ONTAP command reference.

> You use the `security login create` command to add an access method for a user. Learn more about `security login create` in the ONTAP command reference.

ONTAP commands for managing web services

You use the `vserver services web` commands to manage the availability of web services for the cluster or a storage virtual machine (SVM). You use the `vserver services web access` commands to control a role's access to a web service.

If you want to…	Use this command…
Configure a web service for the cluster or anSVM: • Enable or disable a web service • Specify whether only HTTPS can be used for accessing a web service	`vserver services web modify`
Display the configuration and availability of web services for the cluster or anSVM	`vserver services web show`
Authorize a role to access a web service on the cluster or anSVM	`vserver services web access create`
Display the roles that are authorized to access web services on the cluster or anSVM	`vserver services web access show`
Prevent a role from accessing a web service on the cluster or anSVM	`vserver services web access delete`

ONTAP command reference

Commands for managing mount points on ONTAP nodes

The `spi` web service automatically creates a mount point from one node to another node's root volume upon a request to access the node's log files or core files. Although you do not need to manually manage mount points, you can do so by using the `system node root-mount` commands.

If you want to…	Use this command…
Manually create a mount point from one node to another node's root volume	`system node root-mount create` Only a single mount point can exist from one node to another.
Display existing mount points on the nodes in the cluster, including the time a mount point was created and its current state	`system node root-mount show`
Delete a mount point from one node to another node's root volume and force connections to the mount point to close	`system node root-mount delete`

Manage SSL in ONTAP

Use the `security ssl` commands to manage the SSL protocol for the cluster or a storage virtual machine (SVM). SSL protocol improves the security of web access by using a digital certificate to establish an encrypted connection between a web server and a browser.

You can manage SSL for the cluster or a storage virtual machine (SVM) in the following ways:

- Enabling SSL
- Generating and installing a digital certificate and associating it with the cluster or SVM
- Displaying the SSL configuration to see whether SSL has been enabled, and, if available, the SSL certificate name
- Setting up firewall policies for the cluster or SVM, so that web access requests can go through
- Defining which SSL versions can be used
- Restricting access to only HTTPS requests for a web service

Commands for managing SSL

You use the `security ssl` commands to manage the SSL protocol for the cluster or a storage virtual machine (SVM).

If you want to…	Use this command…
Enable SSL for the cluster or an SVM, and associate a digital certificate with it	`security ssl modify`
Display the SSL configuration and certificate name for the cluster or an SVM	`security ssl show`

Learn more about `security ssl modify` and `security ssl show` in the ONTAP command reference.

Use HSTS for ONTAP web services

HTTP Strict Transport Security (HSTS) is a web security policy mechanism that helps protect websites against man-in-the-middle attacks such as protocol downgrade attacks and cookie hijacking. By enforcing the use of HTTPS, HSTS ensures that all communications between the user’s browser and the server are encrypted. Beginning with ONTAP 9.17.1, ONTAP can enforce HTTPS connections for ONTAP web services.

> HSTS is enforced by the web browser only after an initial secure HTTPS connection is established with ONTAP. If the browser does not establish an initial secure connection, HSTS will not be enforced. Refer to your browser documentation for information on HSTS management.

About this task

- For 9.17.1 and above, HSTS is enabled by default for newly installed ONTAP clusters. When you upgrade to 9.17.1, HSTS is not enabled by default. You must enable HSTS after the upgrade.
- HSTS is supported for all ONTAP web services.

Before you begin

- Advanced privileges are required for the following tasks.

Show HSTS configuration

You can show the current HSTS configuration to check if it is enabled and view the maximum age setting.

Steps

1. Use the `system services web show` command to show the current web services configuration, including HSTS settings:

```
cluster-1::system services web*> show

                     External Web Services: true
                                 HTTP Port: 80
                                HTTPS Port: 443
                           Protocol Status: online
                         Per Address Limit: 80
                       Wait Queue Capacity: 192
                              HTTP Enabled: true
                   CSRF Protection Enabled: true
Maximum Number of Concurrent CSRF Tokens: 500
       CSRF Token Idle Timeout (Seconds): 900
   CSRF Token Absolute Timeout (Seconds): 0
          Allow Web Management via Cloud: true
Enforce Network Interface Service-Policy: -
                              HSTS Enabled: true
                    HSTS max age (Seconds): 63072000
```

Enable HSTS and set the maximum age

Beginning with ONTAP 9.17.1, HSTS is enabled by default on new ONTAP cluster. If you upgrade an existing cluster to 9.17.1 or later, you need to manually enable HSTS on your cluster to enforce use of HTTPS. You can enable HSTS and set the maximum age. You can change the maximum age at any time if HSTS is enabled. Once HSTS is enabled, browsers will begin enforcing secure connections only after an initial secure connection is established.

Steps

1. Use the `system services web modify` command to enable HSTS or modify the maximum age:

   ```
   system services web modify -hsts-enabled true -hsts-max-age <seconds>
   ```

   `-hsts-max-age` specifies the duration in seconds for which the browser will remember to enforce HTTPS. The default value is 63072000 seconds (two years).

Disable HSTS

Browsers save the HSTS maximum age setting with each connection, and they continue to enforce HSTS for the entire duration even if HSTS is disabled on ONTAP. It will take up to the configured maximum age duration for the browser to stop enforcing HSTS after it is disabled. If a secure connection becomes impossible during this time, browsers enforcing HSTS will not permit access to ONTAP web services until the issue is resolved or the browser's maximum age expires.

Steps

1. Disable HSTS using the `system services web modify` command:

   ```
   system services web modify -hsts-enabled false
   ```

RFC 6797 - HTTP Strict Transport Security (HSTS)

Troubleshoot ONTAP web service access problems

Configuration errors cause web service access problems to occur. You can address the errors by ensuring that the LIF, firewall policy, web protocol engine, web services, digital certificates, and user access authorization are all configured correctly.

The following table helps you identify and address web service configuration errors:

This access problem…	Occurs because of this configuration error…	To address the error…
Your web browser returns an `unable to connect` or `failure to establish a connection` error when you try to access a web service.	Your LIF might be configured incorrectly.	Ensure that you can ping the LIF that provides the web service. You use the `network ping` command to ping a LIF.
	Your firewall might be configured incorrectly.	Ensure that a firewall policy is set up to support HTTP or HTTPS and that the policy is assigned to the LIF that provides the web service. You use the `system services firewall policy` commands to manage firewall policies. You use the `network interface modify` command with the `-firewall -policy` parameter to associate a policy with a LIF.
	Your web protocol engine might be disabled.	Ensure that the web protocol engine is enabled so that web services are accessible. You use the `system services web` commands to manage the web protocol engine for the cluster.

This access problem…	Occurs because of this configuration error…	To address the error…
Your web browser returns a `not found` error when you try to access a web service.	The web service might be disabled.	Ensure that each web service that you want to allow access to is enabled individually. You use the `vserver services web modify` command to enable a web service for access.
The web browser fails to log in to a web service with a user's account name and password.	The user cannot be authenticated, the access method is not correct, or the user is not authorized to access the web service.	Ensure that the user account exists and is configured with the correct access method and authentication method. Also, ensure that the user's role is authorized to access the web service. You use the `security login` commands to manage user accounts and their access methods and authentication methods. Accessing the ONTAP API web service requires the `ontapi` access method. Accessing all other web services requires the `http` access method. You use the `vserver services web access` commands to manage a role's access to a web service.

This access problem…	Occurs because of this configuration error…	To address the error…
You connect to your web service with HTTPS, and your web browser indicates that your connection is interrupted.	You might not have SSL enabled on the cluster or storage virtual machine (SVM) that provides the web service.	Ensure that the cluster or SVM has SSL enabled and that the digital certificate is valid. You use the `security ssl` commands to manage SSL configuration for HTTP servers and the `security certificate show` command to display digital certificate information.
You connect to your web service with HTTPS, and your web browser indicates that the connection is untrusted.	You might be using a self-signed digital certificate.	Ensure that the digital certificate associated with the cluster or SVM is signed by a trusted CA. You use the `security certificate generate-csr` command to generate a digital certificate signing request and the `security certificate install` command to install a CA-signed digital certificate. You use the `security ssl` commands to manage the SSL configuration for the cluster or SVM that provides the web service.

* security ssl

Verify the identity of remote servers using certificates

Learn about verifying the identity of remote servers using certificates in ONTAP

ONTAP supports security certificate features to verify the identity of remote servers.

ONTAP software enables secure connections using these digital certificate features and protocols:

* Online Certificate Status Protocol (OCSP) validates the status of digital certificate requests from ONTAP services using SSL and Transport Layer Security (TLS) connections. This feature is disabled by default.
* A default set of trusted root certificates is included with ONTAP software.
* Key Management Interoperability Protocol (KMIP) certificates enable mutual authentication of a cluster and a KMIP server.

Verify digital certificates are valid using OCSP in ONTAP

Online Certificate Status Protocol (OCSP) enables ONTAP applications that use Transport Layer Security (TLS) communications to receive digital certificate status when OCSP is enabled. You can enable or disable OCSP certificate status checks for specific applications at any time. By default, OCSP certificate status checking is disabled.

Before you begin

You need advanced privilege level access to perform this task.

About this task

OCSP supports the following applications:

* AutoSupport
* Event Management System (EMS)
* LDAP over TLS
* Key Management Interoperability Protocol (KMIP)
* Audit Logging
* FabricPool
* SSH (beginning with ONTAP 9.13.1)

Steps

1. Set the privilege level to advanced: `set -privilege advanced`.
2. To enable or disable OCSP certificate status checks for specific ONTAP applications, use the appropriate command.

If you want OCSP certificate status checks for some applications to be…	Use the command…
Enabled	`security config ocsp enable -app app name`
Disabled	`security config ocsp disable -app app name`

The following command enables OCSP support for AutoSupport and EMS.

```
cluster::*> security config ocsp enable -app asup,ems
```

When OCSP is enabled, the application receives one of the following responses:

- Good - the certificate is valid and communication proceeds.
- Revoked - the certificate is permanently deemed as not trustworthy by its issuing Certificate Authority and communication fails to proceed.
- Unknown - the server does not have any status information about the certificate and communication fails to proceed.
- OCSP server information is missing in the certificate - the server acts as if OCSP is disabled and continues with TLS communication, but no status check occurs.
- No response from OCSP server - the application fails to proceed.

3. To enable or disable OCSP certificate status checks for all applications using TLS communications, use the appropriate command.

If you want OCSP certificate status checks for all applications to be…	Use the command…

Enabled	`security config ocsp enable`
	
	`-app all`

Disabled	`security config ocsp disable`
	
	`-app all`

When enabled, all applications receive a signed response signifying that the specified certificate is good, revoked, or unknown. In the case of a revoked certificate, the application will fail to proceed. If the application fails to receive a response from the OCSP server or if the server is unreachable, the application will fail to proceed.

4. Use the `security config ocsp show` command to display all the applications that support OCSP and their support status.

```
cluster::*> security config ocsp show
        Application                        OCSP Enabled?
        --------------------               ---------------------
        autosupport                        false
        audit_log                          false
        fabricpool                         false
        ems                                false
        kmip                               false
        ldap_ad                            true
        ldap_nis_namemap                   true
        ssh                                true

        8 entries were displayed.
```

- security config ocsp show

View default certificates for TLS-based applications in ONTAP

ONTAP provides a default set of trusted root certificates for ONTAP applications using Transport Layer Security (TLS).

Before you begin

The default certificates are installed only on the admin SVM during its creation, or during an upgrade.

About this task

The current applications that act as a client and require certificate validation are AutoSupport, EMS, LDAP, Audit Logging, FabricPool, and KMIP.

When certificates expire, an EMS message is invoked that requests the user to delete the certificates. The default certificates can only be deleted at the advanced privilege level.

> Deleting the default certificates may result in some ONTAP applications not functioning as expected (for example, AutoSupport and Audit Logging).

Step

1. You can view the default certificates that are installed on the admin SVM by using the security certificate show command:

   `security certificate show -vserver –type server-ca`

```
cluster1::> security certificate show

Vserver    Serial Number   Certificate Name
Type
---------- --------------- ----------------------------------------
---------
vs0        4F4E4D7B         www.example.com
server
    Certificate Authority:  www.example.com
          Expiration Date: Thu Feb 28 16:08:28 2013
```

Learn more about `security certificate show` in the ONTAP command reference.

Mutually authenticate the cluster and a KMIP server

Mutually authenticating the ONTAP cluster and a KMIP server overview

Mutually authenticating the cluster and an external key manager such as a Key Management Interoperability Protocol (KMIP) server enables the key manager to communicate with the cluster by using KMIP over SSL. You do so when an application or certain functionality (for example, the Storage Encryption functionality) requires secure keys to provide secure data access.

Generate a certificate signing request for the cluster in ONTAP

You can use the security certificate `generate-csr` command to generate a certificate signing request (CSR). After processing your request, the certificate authority (CA) sends you the signed digital certificate.

Before you begin

You must be a cluster administrator or SVM administrator to perform this task.

Steps

1. Generate a CSR:

```
security certificate generate-csr -common-name <FQDN_or_common_name>
-size 512|1024|1536|2048 -country <country> -state <state> -locality
<locality> -organization <organization> -unit <unit> -email-addr
<email_of_contact> -hash-function SHA1|SHA256|MD5
```

Learn more about `security certificate generate-csr` in the ONTAP command reference.

The following command creates a CSR with a 2,048-bit private key generated by the SHA256 hashing function for use by the Software group in the IT department of a company whose custom common name is server1.companyname.com, located in Sunnyvale, California, USA. The email address of the SVM contact administrator is web@example.com. The system displays the CSR and the private key in the output.

```
cluster1::>security certificate generate-csr -common-name
server1.companyname.com -size 2048 -country US -state California -
locality Sunnyvale -organization IT -unit Software -email-addr
web@example.com -hash-function SHA256
Certificate Signing Request :
-----BEGIN CERTIFICATE REQUEST-----
<certificate_value>
-----END CERTIFICATE REQUEST-----
Private Key :
24 | Administrator Authentication and RBAC
-----BEGIN RSA PRIVATE KEY-----
<key_value>
-----END RSA PRIVATE KEY-----
Note: Please keep a copy of your certificate request and private key
for future reference.
```

2. Copy the certificate request from the CSR output, and then send it in electronic form (such as email) to a trusted third-party CA for signing.

   After processing your request, the CA sends you the signed digital certificate. You should keep a copy of the private key and the CA-signed digital certificate.

Install a CA-signed server certificate for the ONTAP cluster

To enable an SSL server to authenticate the cluster or storage virtual machine (SVM) as an SSL client, you install a digital certificate with the client type on the cluster or SVM. Then you provide the client-ca certificate to the SSL server administrator for installation on the server.

Before you begin

You must have already installed the root certificate of the SSL server on the cluster or SVM with the `server-ca` certificate type.

Steps

1. To use a self-signed digital certificate for client authentication, use the `security certificate create` command with the `type client` parameter.

   Learn more about `security certificate create` in the ONTAP command reference.

2. To use a CA-signed digital certificate for client authentication, complete the following steps:

   a. Generate a digital certificate signing request (CSR) by using the security certificate `generate-csr` command.

      ONTAP displays the CSR output, which includes a certificate request and private key, and reminds you to copy the output to a file for future reference.

b. Send the certificate request from the CSR output in an electronic form (such as email) to a trusted CA for signing.

   You should keep a copy of the private key and the CA-signed certificate for future reference.

   After processing your request, the CA sends you the signed digital certificate.

c. Install the CA-signed certificate by using the `security certificate install` command with the `-type client` parameter.

d. Enter the certificate and the private key when you are prompted, and then press **Enter**.

e. Enter any additional root or intermediate certificates when you are prompted, and then press **Enter**.

   You install an intermediate certificate on the cluster or SVM if a certificate chain that begins at the trusted root CA, and ends with the SSL certificate issued to you, is missing the intermediate certificates. An intermediate certificate is a subordinate certificate issued by the trusted root specifically to issue end-entity server certificates. The result is a certificate chain that begins at the trusted root CA, goes through the intermediate certificate, and ends with the SSL certificate issued to you.

3. Provide the `client-ca` certificate of the cluster or SVM to the administrator of the SSL server for installation on the server.

   The security certificate show command with the `-instance` and `-type client-ca` parameters displays the `client-ca` certificate information.

Install a CA-signed client certificate for the KMIP server in ONTAP

The certificate subtype of Key Management Interoperability Protocol (KMIP) (the -subtype kmip-cert parameter), along with the client and server-ca types, specifies that the certificate is used for mutually authenticating the cluster and an external key manager, such as a KMIP server.

About this task

Install a KMIP certificate to authenticate a KMIP server as an SSL server to the cluster.

Steps

1. Use the `security certificate install` command with the `-type server-ca` and `-subtype kmip-cert` parameters to install a KMIP certificate for the KMIP server.
2. When you are prompted, enter the certificate, and then press Enter.

   ONTAP reminds you to keep a copy of the certificate for future reference.

```
cluster1::> security certificate install -type server-ca -subtype kmip-
cert
-vserver cluster1

Please enter Certificate: Press <Enter> when done
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----

You should keep a copy of the CA-signed digital certificate for future
reference.

cluster1::>
```

- security certificate install

Security and data encryption

Autonomous Ransomware Protection

Learn about ONTAP Autonomous Ransomware Protection

Beginning with ONTAP 9.10.1, ONTAP administrators can enable Autonomous Ransomware Protection (ARP) to perform workload analysis in NAS (NFS and SMB) environments to proactively detect and warn about abnormal activity that might indicate a ransomware attack. Beginning with ONTAP 9.17.1, ARP also supports block-device volumes, including SAN volumes containing LUNs, or NAS volume containing virtual disks from hypervisors such as VMware, Hyper-V, and KVM.

ARP is built directly into ONTAP, ensuring integrated control and coordination with ONTAP's other features. ARP operates in real-time, processing data as it's written to or read from the file system, and detecting and responding to potential ransomware attacks quickly.

ARP creates locked snapshots at regular intervals alongside scheduled ones for added protection. It smartly manages snapshot retention duration. If no unusual activity is detected, snapshots are quickly recycled. However, if an attack is detected, a snapshot created before the start of an attack is kept for an extended period.

Licenses and enablement

ARP support is included with the ONTAP ONE license. If you do not have the ONTAP One license, other licenses are available for ARP use that differ depending on your version of ONTAP.

ONTAP releases	License
ONTAP 9.11.1 and later	`Anti_ransomware`
ONTAP 9.10.1	`MT_EK_MGMT` (Multi-Tenant Key Management)

- If you are upgrading from ONTAP 9.10.1 to ONTAP 9.11.1 or later and ARP is already configured on your system, you do not need to install the new `Anti-ransomware` license. For new ARP configurations, the new license is required.
- If you are reverting from ONTAP 9.11.1 or later to ONTAP 9.10.1, and you have enabled ARP with the Anti_ransomware license, you will see a warning message and might need to reconfigure ARP. Learn about reverting ARP.

You can enable Autonomous Ransomware Protection (ARP) on an existing volume or create a new volume and enable ARP.

ONTAP ransomware protection strategy

An effective ransomware detection strategy should include more than a single layer of protection.

An analogy would be the safety features of a vehicle. You don't rely on a single feature, such as a seatbelt, to completely protect you in an accident. Air bags, anti-lock brakes, and forward-collision warning are all additional safety features that will lead to a much better outcome. Ransomware protection should be viewed in the same way.

While ONTAP includes features like FPolicy, snapshots, SnapLock, and Active IQ Digital Advisor (also known as Digital Advisor) to help protect from ransomware, the following information focuses on the ARP feature with machine learning capabilities.

To learn more about other features in the NetApp portfolio that safeguard against ransomware, see Ransomware and NetApp's protection portfolio.

What ARP detects

ONTAP ARP is designed to protect against denial-of-service attacks where the attacker withholds data until a ransom is paid. ARP offers real-time ransomware detection based on the following:

- Identification of incoming data as either encrypted or plain text.
- Analytics that detect:
  - **Entropy**: (Used in NAS and SAN) An evaluation of the randomness of data in a file
  - **File extension types**: (Used in NAS only) A file extension that does not conform to expected extension types
  - **File IOPS**: (Used in NAS only beginning with ONTAP 9.11.1) A surge in abnormal volume activity with data encryption

ARP detects the spread of most ransomware attacks after only a small number of files are encrypted, responds automatically to protect data, and alerts you that a suspected attack is happening.

> No ransomware detection or prevention system can completely guarantee safety from a ransomware attack. Although it's possible an attack might go undetected, ARP acts as an important additional layer of defense if anti-virus software has failed to detect an intrusion.

Learn about ARP modes

After ARP is turned on for a volume, it progresses through two distinct modes. ARP uses a learning or evaluation period to establish a baseline of normal workload behavior. During that period, ARP analyzes system metrics to develop an alert profile before enabling active protection. After ARP transitions to an active detection mode, it begins monitoring abnormal activity in real time, automatically taking protective actions and generating alerts if abnormal behavior is detected.

For ARP, the learning mode and active mode behaviors differ by ONTAP version, volume type, and protocol (NAS or SAN).

NAS environments and mode types

NAS environments use learning and active modes. For ARP/AI running in NAS environments beginning in ONTAP 9.16.1, there is no learning period when ARP is used with FlexVol volumes.

The following table summarizes the differences between ONTAP 9.10.1 and later versions for NAS environments.

<table>
<tr><th>Mode</th><th>Description</th><th>Volume types and versions</th></tr>
<tr><td>Learning</td><td>For ONTAP 9.15.1 to 9.10.1, ARP is automatically set to learning mode when you enable ARP. In learning mode, the ONTAP system develops an alert profile based on the analytic areas: entropy, file extension types, and file IOPS. It’s recommended that you leave ARP in learning mode for 30 days. Beginning with ONTAP 9.13.1, ARP automatically determines the optimal learning interval and automates the switch, which might occur before 30 days. For versions earlier than ONTAP 9.13.1, you can make the switch manually.

Learn more about switching from learning to active mode.

The command <code>security anti-ransomware volume workload-behavior show</code> shows file extensions that have been detected in the volume. If you run this command early in learning mode and it shows an accurate representation of file types, you should not use that data as a basis to move to active mode, as ONTAP is still collecting other metrics. Learn more about <code>security anti-ransomware volume workload-behavior show</code> in the ONTAP command reference.</td><td>• FlexVol volumes with ONTAP 9.15.1 to 9.10.1
• FlexGroup volumes with ONTAP 9.13.1 and later</td></tr>
<tr><td>Active</td><td>After running ARP in learning mode for enough time to assess workload characteristics, you can switch to active mode and start protecting your data. Beginning with ONTAP 9.13.1, ARP automatically determines the optimal learning interval and automates the switch, which might occur before 30 days.

With ONTAP 9.10.1 to 9.15.1, ARP switches to active mode after the optimal learning period is completed. After ARP has switched to active mode, ONTAP creates ARP snapshots to protect the data if a threat is detected.

In active mode, if a file extension is flagged as abnormal, you should evaluate the alert. You can act on the alert to protect your data, or you can mark the alert as a false positive. Marking an alert as a false positive updates the alert profile. For example, if the alert is triggered by a new file extension and you mark the alert as a false positive, you will not receive an alert the next time that the file extension is observed.</td><td>All supported ONTAP versions and FlexVol and FlexGroup volumes</td></tr>
</table>

SAN environments and mode types

SAN environments use *evaluation* periods (similar to learning modes in NAS environments) before transitioning to active detection automatically. The following table summarizes evaluation and active modes.

Mode	Description	Volume types and versions
Evaluation	A two- to four-week evaluation period is performed to determine baseline encryption behavior. You can determine if the evaluation period is complete by running the `security anti-ransomware volume show` command and checking `Block device detection status`. Learn more about SAN volumes and the entropy evaluation period.	• FlexVol volumes with ONTAP 9.17.1 and later
Active	After the evaluation period, you can determine if the ARP SAN protection is active by running the `security anti-ransomware volume show` command and checking `Block device detection status`. A status of `Active_suitable_workload` indicates that the evaluated amount of entropy can be successfully monitored. ARP automatically adjusts the adaptive threshold according to data reviewed during the evaluation.	• FlexVol volumes with ONTAP 9.17.1 and later

Threat assessment and ARP snapshots

ARP assesses threat probability based on incoming data measured against learned analytics. When ARP detects an abnormality, a measurement is assigned. A snapshot might be assigned at the time of detection or at regular intervals.

ARP thresholds

- **Low**: The earliest detection of an abnormality in the volume (for example, a new file extension is observed in the volume). This level of detection is only available in versions prior to ONTAP 9.16.1 that do not have ARP/AI.
  - Beginning with ONTAP 9.11.1, you can customize the detection parameters for ARP.
  - In ONTAP 9.10.1, the threshold for escalation to moderate is 100 or more files.
- **Moderate**: High entropy is detected or multiple files with the same never-seen-before file extension are observed. This is the baseline detection level in ONTAP 9.16.1 and later with ARP/AI.

The threat escalates to moderate after ONTAP runs an analytics report determining if the abnormality matches a ransomware profile. When the attack probability is moderate, ONTAP generates an EMS notification prompting you to assess the threat. ONTAP does not send alerts about low threats; however, beginning with ONTAP 9.14.1, you can modify default alert settings. For more information, see Respond to abnormal activity.

You can view information about moderate threats in System Manager's **Events** section or with the `security anti-ransomware volume show` command. Low threat events can also be viewed using the `security anti-ransomware volume show` command in versions prior to ONTAP 9.16.1 that do not have ARP/AI. Learn more about `security anti-ransomware volume show` in the ONTAP command reference.

ARP snapshots

In ONTAP 9.16.1 and earlier, ARP creates a snapshot when early signs of an attack are detected. A detailed analysis is then conducted to confirm or dismiss the potential attack. Because ARP snapshots are created proactively, even before an attack is fully confirmed, they might also be generated at regular intervals for certain legitimate applications. The presence of these snapshots should not be regarded as an anomaly. If an attack is confirmed, the attack probability is escalated to `Moderate`, and an attack notification is generated.

Beginning with ONTAP 9.17.1, ARP snapshots are generated at regular intervals for both NAS and SAN volumes. ONTAP prepends a name to the ARP snapshot to make it easily identifiable.

Beginning with ONTAP 9.11.1, you can modify the retention settings. For more information, see Modify options for snapshots.

The following table summarizes ARP snapshot differences between ONTAP 9.16.1 and earlier and ONTAP 9.17.1.

<table>
<tr><th>Feature</th><th>ONTAP 9.16.1 and earlier</th><th>ONTAP 9.17.1 and later</th></tr>
<tr><td>Creation trigger</td><td>High entropy is detected
A new file extension is detected (9.15.1 and earlier)
A surge of file operations is detected (9.15.1 and earlier)
Snapshot creation interval is based on trigger type.</td><td>Snapshots are created at fixed 4-hour intervals, regardless of any specific trigger, and are not necessarily indicative of an attack.</td></tr>
<tr><td>Prepended name convention</td><td>"Anti_ransomware_backup"</td><td>"Anti_ransomware_periodic_backup"</td></tr>
<tr><td>Deletion behavior</td><td>ARP snapshot is locked and cannot be deleted by the administrator</td><td>ARP snapshot is locked and cannot be deleted by the administrator</td></tr>
<tr><td>Maximum snapshot count</td><td>Six snapshot configurable limit</td><td>Six snapshot configurable limit</td></tr>
<tr><td>Retention period</td><td>Determined based on trigger conditions (not fixed)
Snapshots created before the attack are retained until administrator marks the attack as true or a false positive (clear-suspect).</td><td>Snapshots are normally retained for 12 hours.
NAS volumes: If an attack is confirmed by file-analysis, snapshots created before the attack are retained until the administrator marks the attack as true or a false positive (clear-suspect).
SAN volume or VM datastores: If an attack is confirmed by block-entropy analysis, snapshots created before the attack are retained for 10 days (configurable).

The retention period of a snapshot created before the onset of an attack is extended to 10 days (configurable).</td></tr>
</table>

Feature	ONTAP 9.16.1 and earlier	ONTAP 9.17.1 and later
Clear-suspect action	Administrators can perform a clear-suspect action which sets retention based on confirmation: • 24 hours for false-positive retention • 7 days for true-positive retention This precautionary retention behavior doesn't exist earlier than ONTAP 9.16.1	Administrators can perform a clear-suspect action which sets retention based on confirmation: • 24 hours for false-positive retention • 7 days for true-positive retention
Expiration time	None	An expiration time is set for all snapshots

How to recover data in ONTAP after a ransomware attack

ARP builds on proven ONTAP data protection and disaster recovery technology to respond to ransomware attacks. ARP creates locked snapshots when early signs of an attack are detected in ONTAP 9.16.1 and earlier or at regular intervals in 9.17.1 and later. You'll need to first confirm whether the attack is real or a false positive. If you confirm the attack, the volume can be restored using the ARP snapshot.

Locked snapshots cannot be deleted by normal means. However, if you decide later to mark the attack as a false positive, the locked copy will be deleted.

With the knowledge of the affected files and the time of attack, it is possible to selectively recover the affected files from various snapshots rather than simply reverting the whole volume to one of the snapshots.

See the following topics for more information on responding to an attack and recovering data:

- Respond to abnormal activity
- Recover data from ARP snapshots
- Recover from ONTAP snapshots
- Smart ransomware recovery

Multi-admin verification protection for ARP

Beginning with ONTAP 9.13.1, it's recommended that you enable multi-admin verification (MAV) so that two or more authenticated user admins are required for Autonomous Ransomware Protection (ARP) configuration. For more information, see Enable multi-admin verification.

Autonomous Ransomware Protection with Artificial Intelligence (ARP/AI)

Beginning with ONTAP 9.16.1, ARP improves cyber resiliency by adopting a machine-learning model for anti-ransomware analytics that detects constantly evolving forms of ransomware with 99% accuracy in NAS environments. ARP's machine-learning model is pre-trained on a large dataset of files both before and after a simulated ransomware attack. This resource-intensive training is done outside ONTAP using open-source forensic research datasets to train the model. Customer data is not used throughout the entire modelling pipeline and privacy issues do not exist. The pre-trained model that results from this training is included on-box with ONTAP. This model is not accessible or modifiable through the ONTAP CLI or ONTAP API.

Immediate transition to active protection for ARP/AI with FlexVol volumes

With ARP/AI and FlexVol volumes, there is no learning period. ARP/AI is enabled and active immediately after installation or upgrade to 9.16. After upgrading your cluster to ONTAP 9.16.1, ARP/AI will be automatically enabled for existing and new FlexVol volumes if ARP is already enabled for those volumes.

Learn more about enabling ARP/AI

ARP/AI automatic updates

To keep up-to-date protection against the latest ransomware threats, ARP/AI offers frequent automatic updates that occur outside of regular ONTAP upgrade and release cadences. If you have enabled automatic updates then you will also be able to start receiving automatic security updates to ARP/AI after you select automatic updates for security files. You can also choose to make these updates manually and control when the updates occur.

Beginning with ONTAP 9.16.1, security updates for ARP/AI are available using System Manager in addition to system and firmware updates.

Learn more about ARP/AI updates

Related information

- ONTAP command reference

ONTAP Autonomous Ransomware Protection use cases and considerations

Autonomous Ransomware Protection (ARP) is available for NAS workloads beginning with ONTAP 9.10.1 and SAN workloads beginning in ONTAP 9.17.1. Before deploying ARP, you should be aware of the recommended uses and supported configurations as well as performance implications.

Supported and unsupported configurations

When deciding to use ARP, it’s important to ensure that your volume’s workload is suited to ARP and that it meets required system configurations.

Suitable workloads

ARP is suited for these types of workloads:

- Databases on NFS or SAN storage
- Windows or Linux home directories

  For environments without ARP/AI, users could create files with extensions that aren’t detected in the learning period. Because of this, there is a greater possibility of false positives in this workload.

- Images and video

  For example, health care records and Electronic Design Automation (EDA) data

Unsuitable workloads

ARP is not suited for these types of workloads:

- Workloads with a high frequency of file create or delete operations (hundreds of thousands of files in few seconds; for example, test/development workloads).

* ARP's threat detection depends on its ability to recognize an unusual surge in file create, rename, or delete operations. If the application itself is the source of the file activity, it cannot be effectively distinguished from ransomware activity.
* Workloads where the application or the host encrypts data.

  ARP depends on distinguishing incoming data as encrypted or unencrypted. If the application itself is encrypting the data, then the effectiveness of the feature is reduced. However, ARP can still work based on file activity (delete, overwrite, or create, or a create or rename with a new file extension) and file type.

Supported configurations

ARP is available for NAS NFS and SMB FlexVol volumes beginning with ONTAP 9.10.1. Beginning in 9.17.1, ARP is available for SAN FlexVol volumes for iSCSI, FC, and NVMe with SAN storage.

Support for other configurations and volume types is available in the following ONTAP versions:

	ONTAP 9.17.1	ONTAP 9.16.1	ONTAP 9.15.1	ONTAP 9.14.1	ONTAP 9.13.1	ONTAP 9.12.1	ONTAP 9.11.1	ONTAP 9.10.1
Volumes protected with SnapMirror asynchronous	✓	✓	✓	✓	✓	✓		
SVMs protected with SnapMirror asynchronous (SVM disaster recovery)	✓	✓	✓	✓	✓	✓		
SVM data mobility (`vserver migrate`)	✓	✓	✓	✓	✓	✓		
FlexGroup volumes[1]	✓	✓	✓	✓	✓			
Multi-admin verification	✓	✓	✓	✓	✓			
ARP/AI with automatic updates	✓	✓						

[1] ARP/AI does not support FlexGroup volumes. After an upgrade to ONTAP 9.16.1, FlexGroup volumes enabled for ARP continue to operate with the same ARP model used prior to ARP/AI.

SnapMirror and ARP interoperability

Beginning with ONTAP 9.12.1, ARP is supported on SnapMirror asynchronous destination volumes. ARP is **not** supported with SnapMirror synchronous or SnapMirror active sync.

If a SnapMirror source volume is ARP-enabled, the SnapMirror destination volume automatically acquires the ARP configuration state (such as `dry-run` or `enabled`), ARP training data, and ARP-created snapshot of the source volume. No explicit enablement is required.

Although the destination volume consists of read-only (RO) snapshots, no ARP processing is done on its data. However, when the SnapMirror destination volume is converted to read-write (RW), ARP is automatically enabled on the RW-converted destination volume. The destination volume does not require any additional learning procedures besides what is already recorded on the source volume.

In ONTAP 9.10.1 and 9.11.1, SnapMirror does not transfer the ARP configuration state, training data, and snapshots from source to destination volumes. Because of this, when the SnapMirror destination volume is converted to RW, ARP on the destination volume must be explicitly enabled in learning mode after conversion.

ARP and virtual machines

ARP is supported with virtual machines (VMs). ARP detection behaves differently for changes inside and outside the VM. ARP is not recommended for workloads that involve a large number of highly compressed files (such as 7z and ZIP) or encrypted files (such as password-protected PDF, DOC, or ZIP) within the VM.

Changes outside the VM

ARP can detect file extension changes on an NFS volume outside of the VM if a new extension enters the volume in an encrypted state or if a file extension changes.

Changes inside the VM

If a ransomware attack changes files inside of the VM without making changes outside the VM, ARP detects the threat if the default entropy of the VM is low (for example, .txt, .docx, or .mp4 files). For ONTAP 9.16.1 and earlier, ARP creates a protective snapshot in this scenario but does not generate a threat alert because the file extensions outside of the VM have not been tampered with. Beginning with SAN support in ONTAP 9.17.1, ARP generates a threat alert additionally if it detects an entropy anomaly inside the VM.

If, by default, the files are high entropy (for example, .gzip or password-protected files), ARP's detection capabilities are limited. ARP can still take proactive snapshots in this instance; however, no alerts will be triggered if the file extensions have not been tampered with externally.

For SAN, ARP analyzes entropy statistics at the volume level and triggers detections when an entropy anomaly is found.

Unsupported configurations

ARP is not supported in ONTAP S3 environments.

ARP does not support the following volume configurations:

- FlexGroup volumes (in ONTAP 9.10.1 through 9.12.1). Beginning with ONTAP 9.13.1, FlexGroup volumes are supported but are limited to the ARP model used prior to ARP/AI.
- FlexCache volumes (ARP is supported on origin FlexVol volumes but not on cache volumes)
- Offline volumes
- SnapLock volumes

* SnapMirror active sync
* SnapMirror synchronous
* SnapMirror asynchronous (in ONTAP 9.10.1 and 9.11.1). SnapMirror asynchronous is supported beginning with ONTAP 9.12.1. For more information, see SnapMirror and ARP interoperability.
* Restricted volumes
* Root volumes of storage VMs
* Volumes of stopped storage VMs

ARP performance and frequency considerations

ARP can have a minimal impact on system performance as measured in throughput and peak IOPS. The impact of the ARP feature depends on the specific volume workload. For common workloads, the following configuration limits are recommended:

Workload characteristics	Recommended volume limit per node	Performance degradation when per-node volume limit is exceeded [1]
Read-intensive or the data can be compressed	150	4% of maximum IOPS
Write-intensive and the data cannot be compressed	60	• NAS: 10% of maximum IOPS for ONTAP 9.15.1 and earlier • NAS: 4% of maximum IOPS for ONTAP 9.16.1 and later • SAN: 5% of maximum IOPS for ONTAP 9.17.1 and later

[1] System performance is not degraded beyond these percentages regardless of the number of volumes added in excess of the recommended limits.

Because ARP analytics run in a prioritized sequence, analytics run on each volume less frequently as the number of protected volumes increases.

Multi-admin verification with volumes protected with ARP

Beginning with ONTAP 9.13.1, you can enable multi-admin verification (MAV) for additional security with ARP. MAV ensures that at least two or more authenticated administrators are required to turn off ARP, pause ARP, or mark a suspected attack as a false positive on a protected volume. Learn how to enable MAV for ARP-protected volumes.

You need to define administrators for a MAV group and create MAV rules for the `security anti-ransomware volume disable`, `security anti-ransomware volume pause`, and `security anti-ransomware volume attack clear-suspect` ARP commands you want to protect. Each administrator in the MAV group must approve each new rule request and add the MAV rule again within MAV settings.

Learn more about `security anti-ransomware volume disable`, `security anti-ransomware volume pause`, and `security anti-ransomware volume attack clear-suspect` in the ONTAP command reference.

Beginning with ONTAP 9.14.1, ARP offers alerts for the creation of an ARP snapshot and for the observation of a new file extension. Alerts for these events are disabled by default. Alerts can be set at the volume or SVM level. You can enable the alerts using `security anti-ransomware vserver event-log modify` or at the volume level with `security anti-ransomware volume event-log modify`.

Learn more about `security anti-ransomware vserver event-log modify` and `security anti-ransomware volume event-log modify` in the ONTAP command reference.

Next steps

- Enable Autonomous Ransomware Protection
- Enable MAV for ARP-protected volumes

Enable ONTAP Autonomous Ransomware Protection

Beginning with ONTAP 9.10.1, you can enable Autonomous Ransomware Protection (ARP) on an existing volume or create a new volume and enable ARP from the beginning.

If you want to configure your ONTAP cluster so that all new volumes will be enabled by default for Autonomous Ransomware Protection (ARP), see this related ARP procedure.

About this task

- **(NAS environments only) For ONTAP 9.10.1 to 9.15.1 or ARP with FlexGroup volumes**
  For these versions of ONTAP, you should always enable ARP initially in learning mode (or "dry-run" state). When you first enable ARP in learning mode, the system analyzes the workload to characterize normal behavior. Beginning in active mode can lead to excessive false positive reports.

  It’s recommended that you let ARP run in learning mode for a minimum of 30 days. Beginning with ONTAP 9.13.1, ARP automatically determines the optimal learning period interval and automates the switch, which might occur before 30 days.

- **(NAS environments only) For ONTAP 9.16.1 and later with FlexVol volumes**
  When you enable ARP using System Manager or the CLI, ARP/AI protection is enabled and active immediately. No learning period is required.
- **(SAN environments only) For ONTAP 9.17.1 and later with FlexVol volumes**
  When you enable ARP using System Manager or the CLI, ARP/AI functionality is automatically enabled. Once enabled on a SAN volume, ARP/AI monitors data continuously during an evaluation period to determine if the workloads are suitable for ARP and sets an optimal encryption threshold for detection.

Before you begin

- You must have a storage VM (SVM) with protocols enabled:
  - NAS: NFS or SMB (or both)
  - SAN: iSCSI, FC, or NVMe
- The correct license must be installed for your ONTAP version.
- You must have NAS or SAN workload with clients configured.
- (NAS environments only) The volume you want to set ARP on must have an active junction path.
- The volume must be less than 100% full.
- It’s recommended you configure the EMS system to send email notifications, which will include notices of ARP activity. For more information, see Configure EMS events to send email notifications.

* Beginning with ONTAP 9.13.1, it’s recommended that you enable multi-admin verification (MAV) so that two or more authenticated user admins are required for Autonomous Ransomware Protection (ARP) configuration. For more information, see Enable multi-admin verification.

Enable ARP on a new or existing volume

You can enable ARP using System Manager or the ONTAP CLI.

System Manager

Steps

1. Select **Storage > Volumes**, then select the volume you want to protect.
2. In the **Security** tab of the **Volumes** overview, select **Status** to switch from Disabled to Enabled.
   - (NAS environments only) If you are using ARP with ONTAP 9.15.1 or earlier or ONTAP 9.16.1 with FlexGroup volumes, select **Enabled in learning-mode** in the **Anti-ransomware** box.

     > Beginning with ONTAP 9.13.1, ARP automatically determines the optimal learning period interval and automates the switch. You can disable this setting on the associated storage VM if you want to control the learning mode to active mode transition manually.

     > In existing volumes, learning and active modes only apply to newly written data, not to already existing data in the volume. The existing data is not scanned and analyzed, because the characteristics of earlier normal data traffic are assumed based on the new data after the volume is enabled for ARP.

3. You can verify the ARP state of the volume in the **Anti-ransomware** box.

   To display ARP status for all volumes: In the **Volumes** pane, select **Show/Hide** then ensure that **Anti-ransomware** status is checked.

CLI

The process to enable ARP with the CLI differs if you are enabling it on an existing volume or a new volume.

Enable ARP on an existing volume

1. Modify an existing volume to enable ransomware protection:
   - For NAS environments without ARP/AI or for FlexGroup volumes, use `dry-run` state so that new volumes start in learning mode.
   - For NAS environments running ONTAP 9.16.1 or later or SAN environments with ONTAP 9.17.1, use `enabled` state.

     ```
     security anti-ransomware volume <dry-run|enabled> -volume
     <vol_name> -vserver <svm_name>
     ```

     Learn more about `security anti-ransomware volume dry-run` in the ONTAP command reference.

2. If you upgraded a NAS environment to ONTAP 9.13.1 through ONTAP 9.15.1 and the default state is `dry-run` (learning mode), adaptive learning is enabled so that the change to `enabled` state (active mode) is done automatically. If you do not want this behavior to be automatically enabled, change the setting at the SVM level on all associated volumes:

```
vserver modify <svm_name> -anti-ransomware-auto-switch-from-learning
-to-enabled false
```

3. Verify the ARP state of the volume.

```
security anti-ransomware volume show
```

Enable ARP on a new volume

1. Create a new volume with ARP enabled before provisioning data:
   - For NAS environments without ARP/AI or for FlexGroup volumes, use `dry-run` state so that new volumes start in learning mode.
   - For NAS environments running ONTAP 9.16.1 or later or SAN environments with ONTAP 9.17.1, use `enabled` state.

   ```
   volume create -volume <vol_name> -vserver <svm_name> -aggregate
   <aggr_name> -size <nn> -anti-ransomware-state <dry-run|enabled>
   -junction-path </path_name>
   ```

2. If you upgraded a NAS environment to ONTAP 9.13.1 through ONTAP 9.15.1 and the default state is `dry-run` (learning mode), adaptive learning is enabled so that the change to `enabled` state (active mode) is done automatically. If you do not want this behavior to be automatically enabled, change the setting at the SVM level on all associated volumes:

```
vserver modify <svm_name> -anti-ransomware-auto-switch-from-learning
-to-enabled false
```

3. Verify that the volume is set to `enabled` state.

```
security anti-ransomware volume show
```

Learn more about `security anti-ransomware volume show` in the ONTAP command reference.

- Switch to active mode after a learning period

Enable ONTAP Autonomous Ransomware Protection by default in new volumes

Beginning with ONTAP 9.10.1, you can configure storage VMs (SVMs) so that new volumes are enabled by default with Autonomous Ransomware Protection (ARP). You can modify this setting using System Manager or with the CLI.

If you want to configure only individual new or existing volumes without making ARP the default, see this related ARP procedure.

About this task

By default, new volumes are created with ARP in disabled mode. ARP will only be enabled by default on new volumes created in the SVM after you have enabled anti-ransomware functionality.

ARP will not be automatically enabled on existing volumes. The setting changes described in this procedure only affect new volumes. Learn how to enable ARP for existing volumes.

- **(SAN environments only) For ONTAP 9.17.1 and later with FlexVol volumes**
  When you enable ARP using System Manager or the CLI, ARP/AI functionality is automatically enabled. Once enabled on a SAN volume, ARP/AI monitors data continuously during an evaluation period to determine if the workloads are suitable for ARP and sets an optimal encryption threshold for detection.
- **(NAS environments only) For ONTAP 9.16.1 and later with FlexVol volumes**
  When you enable ARP using System Manager or the CLI, ARP/AI protection is enabled and active immediately. No learning period is required.
- **(NAS environments only) For ONTAP 9.15.1 to 9.10.1 or ARP with FlexGroup volumes**
  By default, new volumes with ARP enabled are set to learning mode (or "dry-run" state) in which the system analyzes the workload to characterize normal behavior. Learning mode can be transitioned to active mode manually (all ARP versions) or automatically (beginning in ARP 9.13.1). With ARP 9.13.1 and later, adaptive learning has been added to ARP analytics so that the switch from learning mode to active mode is done automatically.

Before you begin

- The correct license must be installed for your ONTAP version.
- Volumes must be less than 100% full.
- (NAS environments only) Volumes you want to set ARP on must be protected and have an active junction path.
- Beginning with ONTAP 9.13.1, it's recommended that you enable multi-admin verification (MAV) so that two or more authenticated user admins are required for anti-ransomware operations. Learn more.

Steps

You can use System Manager or the ONTAP CLI to enable ARP by default on new volumes.

System Manager

1. Select **Storage** or **Cluster** (depending on your environment), select **Storage VMs**, and select the storage VM that contains volumes you want to protect with ARP.
2. Navigate to the **Settings** tab. Under **Security**, locate the **Anti-ransomware** tile then select .
3. Check the box to enable anti-ransomware (ARP). Check the additional box to enable ARP on all eligible volumes in the storage VM.
4. For ONTAP 9.13.1 or later, optionally select **Switch automatically from learning to active mode after sufficient learning**. This allows ARP to determine the optimal learning period interval and automate the switch to active mode.

CLI

- Modify an existing SVM to enable ARP by default in new volumes:
  - For NAS environments without ARP/AI or for FlexGroup volumes, use `dry-run` state so that new volumes start in learning mode.
  - For NAS environments running ONTAP 9.16.1 or later or SAN environments with ONTAP 9.17.1, use `enabled` state.

  ```
  vserver modify -vserver <svm_name> -anti-ransomware-default
  -volume-state <dry-run|enabled>
  ```

- Create a new SVM with ARP enabled by default for new volumes:
  - For NAS environments without ARP/AI or for FlexGroup volumes, use `dry-run` state so that new volumes start in learning mode.
  - For NAS environments running ONTAP 9.16.1 or later or SAN environments with ONTAP 9.17.1, use `enabled` state.

  ```
  vserver create -vserver <svm_name> -anti-ransomware-default
  -volume-state <dry-run|enabled>
  ```

- If you upgraded to ONTAP 9.13.1 through ONTAP 9.15.1 and the default state is `dry-run` (learning mode), adaptive learning is enabled so that the change to `enabled` state (active mode) is done automatically. Modify the existing SVM if you do not want this behavior to be automatically enabled:

  ```
  vserver modify <svm_name> -anti-ransomware-auto-switch-from-learning
  -to-enabled false
  ```

- Verify that ARP-enabled volumes show `enabled` state.

  ```
  security anti-ransomware volume show
  ```

  Learn more about `security anti-ransomware volume show` in the ONTAP command reference.

Enable ONTAP ARP/AI

Beginning with ONTAP 9.16.1, ARP has adopted Autonomous Ransomware Protection with Artificial Intelligence (ARP/AI) to improve threat detection and response. After you upgrade your cluster to ONTAP 9.17.1 for SAN or ONTAP 9.16.1 for NAS, ARP/AI will be automatically enabled for FlexVol volumes if ARP is already enabled for those volumes. If you have not enabled ARP or have not enabled ONTAP automatic updates for your cluster, you should follow one of the scenarios described in this procedure.

> ⓘ Before upgrading to an ONTAP version with ARP/AI support, close out any existing ARP detections.

Before you begin

- You must have FlexVol volumes to use ARP/AI. If you have FlexGroup volumes, the ARP model used prior to ARP/AI continues to operate after upgrading to ONTAP 9.16.1 or later.

> ⓘ (NAS environments only) When you upgrade to ONTAP 9.16.1 or later, ARP is enabled and becomes active automatically for any existing ARP instances with FlexVol volumes. Because ARP/AI is trained on an extensive machine learning model, a learning period is no longer required. Any learning periods that have not been completed prior to upgrade will automatically be ended, and the volumes transitioned to active ARP/AI.

Steps

1. Follow the scenario that is specific to your configuration:
   - **SAN environments only**
     - **For new and existing clusters running ONTAP 9.17.1 or later with FlexVol volumes**: When you upgrade to or install ONTAP 9.17.1 or later, you should enable ARP on volumes you intend to protect. When you enable ARP using System Manager or the CLI, ARP/AI functionality is automatically enabled. Once enabled on a SAN volume, ARP/AI monitors data continuously during an evaluation period to determine if the workloads are suitable for ARP and set an optimal encryption threshold for detection.
   - **NAS environments only**
     - **For new clusters running ONTAP 9.16.1 or later with FlexVol volumes**: Enable ARP. ARP is not enabled by default. After you enable ARP, ARP/AI functionality is automatically enabled on the FlexVol volumes you choose to protect.
     - **For existing clusters recently upgraded to ONTAP 9.16.1 and later that have ARP enabled**: No action is needed. ARP/AI automatically becomes the new ARP method of threat protection on the FlexVol volumes you've chosen to protect.
     - **For existing clusters recently upgraded to ONTAP 9.16.1 and later that do not have ARP enabled**: Enable ARP. ARP/AI automatically becomes the new ARP method of threat protection after you enable ARP.

2. After ARP/AI is enabled, decide whether you want ARP/AI protection updates to be delivered and installed automatically or manually.

Related information

- Update ARP/AI

Update ONTAP Autonomous Ransomware Protection with AI (ARP/AI)

To keep protection up to date against the latest ransomware threats, ARP/AI offers automatic updates that occur outside of regular ONTAP release cadences.

Beginning with ONTAP 9.16.1, security updates for ARP/AI are available in System Manager software downloads in addition to system and firmware updates. If your ONTAP cluster is already enrolled in automatic system and firmware updates, you will be automatically notified when ARP/AI security updates are available. You can also change your update preferences so that ONTAP installs security updates automatically.

If you want to manually update ARP/AI, you can download updates from the NetApp Support Site and install them using System Manager.

About this task

You can only update ARP/AI using System Manager.

Select an update preference for ARP/AI

In System Manager, the settings on the Enable automatic updates page for security files are set to `Show notifications` if you are already enrolled in automatic firmware and system updates. You can change the update settings to `Automatically update` if you'd prefer ONTAP to apply the latest updates automatically. If you use a dark site or prefer to perform updates manually, you can choose to show notifications or automatically dismiss security updates.

Before you begin

For automatic security updates, AutoSupport and AutoSupport OnDemand should be enabled and the transport protocol should be set to HTTPS.

Steps

1. In System Manager, click **Cluster > Settings > Software updates**.
2. In the **Software updates** section, select →.
3. From the **Software updates** page, select the **All other updates** tab.
4. Select the **All other updates** tab and click **More**.
5. Select **Edit automatic update settings**.
6. From the Automatic update settings page, select **Security Files**.
7. Specify the action to be taken for security files (ARP/AI updates).

   You can choose to automatically update, show notifications, or automatically dismiss updates.

   > ⓘ For security updates to automatically update, AutoSupport and AutoSupport OnDemand should be enabled and the transport protocol should be set to HTTPS.

8. Accept the terms and conditions and select **Save**.

Manually update ARP/AI with the latest security package

Follow the appropriate procedure depending on whether you are registered with Active IQ Unified Manager.

> Be sure to install only a more recent ARP update than your current version to avoid any unintended ARP downgrades.

ONTAP 9.16.1 and later with Digital Advisor

1. In System Manager, go to **Dashboard**.

   In the **Health** section, a message displays if there are any recommended security updates for the cluster.

2. Click on the alert message.
3. Next to the security updates in the list of recommended updates, select **Actions**.
4. Click **Update** to install the update immediately or **Schedule** to schedule it for later.

   If the update is already scheduled, you can **Edit** or **Cancel** it.

ONTAP 9.16.1 and later without Digital Advisor

1. Navigate to the NetApp Support Site and log in.
2. Complete the prompts and download the security package that you want to use to update your cluster ARP/AI.
3. Copy the files to an HTTP or FTP server on your network or to a local folder that can be accessed by the cluster with ARP/AI.
4. In System Manager, click **Cluster > Settings > Software updates**.
5. In **Software updates**, select the **All other updates** tab.
6. In the **Manual updates** pane, click **Add security files** and add the files using one of these preferences:
   - **Download from server**: Enter the URL for the security file package.
   - **Upload from local client**: Navigate to the downloaded TGZ file.

   > Ensure that the file name begins with `ontap_security_file_arpai_` and has `.tgz` as a file extension.

7. Click **Add** to apply the updates.

Verify ARP/AI updates

To view a history of automatic updates that were dismissed or failed to install, do the following:

1. In System Manager, click **Cluster > Settings > Software updates**.
2. In the **Software updates** section, select →.
3. From the **Software updates** page, select the **All other updates** tab and click **More**.
4. Select **View all automatic updates**.

Switch to active mode in ONTAP ARP after a learning period

For NAS environments, manually or automatically switch an ARP-enabled volume from learning mode to active mode. You'll need to switch modes if you are using ARP with ONTAP 9.15.1 and earlier or if your ARP is running on FlexGroup volumes.

After ARP has completed a learning mode run of a recommended minimum of 30 days you can manually switch to active mode. Beginning with ONTAP 9.13.1, ARP automatically determines the optimal learning period interval and automates the switch, which might occur before 30 days.

If you are using ARP on FlexVol volumes with ONTAP 9.16.1 or later, ARP/AI protection is enabled and becomes active automatically. No learning period is required.

> In existing volumes, learning and active modes only apply to newly written data, not to already existing data in the volume. The existing data is not scanned and analyzed, because the characteristics of earlier normal data traffic are assumed based on the new data after the volume is enabled for ARP.

Manually switch to active mode after learning period

For ONTAP 9.10.1 to 9.15.1 and ARP with FlexGroup volumes, you can manually transition from ARP learning mode to active mode using System Manager or the ONTAP CLI after the learning period is complete.

About this task

The manual transition to active mode after a learning period described in this procedure is specific to NAS environments.

Steps

You can use System Manager or the ONTAP CLI to switch from learning mode to active mode.

System Manager

1. Select **Storage > Volumes** and then select the volume that is ready for active mode.
2. In the **Security** tab of the **Volumes** overview, select **Switch to active mode** in the Anti-ransomware box.
3. You can verify the ARP state of the volume in the **Anti-ransomware** box.

CLI

1. Modify the protected volume to switch to active mode if not already done automatically:

   ```
   security anti-ransomware volume enable -volume <vol_name> -vserver
   <svm_name>
   ```

   You can also switch to active mode with the modify volume command:

   ```
   volume modify -volume <vol_name> -vserver <svm_name> -anti
   -ransomware-state enabled
   ```

2. Verify the ARP state of the volume.

   ```
   security anti-ransomware volume show
   ```

Automatic switching from learning mode to active mode

Beginning with ONTAP 9.13.1, adaptive learning has been added to ARP analytics and the switch from learning mode to active mode is done automatically. The autonomous decision by ARP to automatically switch from learning mode to active mode is based on the configuration settings of the following options:

```
-anti-ransomware-auto-switch-minimum-incoming-data-percent
-anti-ransomware-auto-switch-duration-without-new-file-extension
-anti-ransomware-auto-switch-minimum-learning-period
-anti-ransomware-auto-switch-minimum-file-count
-anti-ransomware-auto-switch-minimum-file-extension
```

If auto-switch is enabled, the volume will switch to active mode automatically after a maximum of 30 days, even if all conditions are not met. This 30-day limit is fixed and cannot be changed.

For more information on ARP configuration options, including default values, see the ONTAP command reference.

Related information

- security anti-ransomware volume

Learn about the ONTAP ARP evaluation period for SAN volumes

Beginning with ONTAP 9.17.1, ARP requires an evaluation period to determine if entropy levels for SAN volume workloads are suitable for ransomware protection. After ARP is enabled on a SAN volume, it monitors data continuously during an evaluation period to determine an optimal encryption threshold. ARP distinguishes between suitable and unsuitable workloads in the evaluated SAN volume and, if the workloads are determined to be suitable for protection, automatically sets an encryption threshold based on evaluation period statistics.

Understand entropy evaluation

The system collects continuous encryption statistics in 10-minute intervals. During the evaluation, ARP snapshots are also continuously created every four hours. If the encryption percentage within an interval exceeds the optimal encryption threshold identified for this volume, an alert is triggered and snapshot retention time is increased.

Confirm that the evaluation period is active

You can confirm that the evaluation is active by running the following command and confirming a status of `evaluation_period`. The evaluation period applies to volumes containing either LUNs or VMDKs. If a volume does not contain a LUN or VMDK, the evaluation status will not be displayed.

```
security anti-ransomware volume show -vserver <svm_name> -volume
<volume_name>
```

Example response:

```
Vserver Name                                  : vs1
Volume Name                                   : v1
State                                         : enabled
Attack Probability                            : none
Attack Timeline                               : -
Number of Attacks                             : -
Attack Detected By                            : -
Block device detection status                 : evaluation_period
```

Monitor evaluation period data collection

You can monitor encryption detection in real time by running the following command. The command returns a histogram showing the amount of data in each encryption percentage range. The histogram is updated every 10 minutes.

```
security anti-ransomware volume entropy-stat show-encryption-percentage-
histogram -vserver <svm_name> -name <lun_name> -duration real_time
```

Example response:

```
Vserver     Name              Entropy Range   Seen N Time     Data Written
----------  ----------------  --------------- --------------
-------------
vs0         lun1              0-5%            4               100MB
vs0         lun1              6-10%           10              900MB
vs0         lun1              11-15%          20              40MB
vs0         lun1              16-20%          10              70MB
vs0         lun1              21-25%          60              450MB
vs0         lun1              26-30%          4               100MB
vs0         lun1              31-35%          10              900MB
vs0         lun1              36-40%          20              40MB
vs0         lun1              41-45%          0               0
vs0         lun1              46-50%          0               0
vs0         lun1              51-55%          0               0
vs0         lun1              56-60%          0               0
vs0         lun1              61-65%          0               0
vs0         lun1              66-70%          0               0
vs0         lun1              71-75%          0               0
vs0         lun1              76-80%          0               0
vs0         lun1              81-85%          0               0
vs0         lun1              86-90%          0               0
vs0         lun1              91-95%          0               0
vs0         lun1              96-100%         0               0

20 entries were displayed.
```

Suitable workloads and adaptive thresholds

The evaluation ends with one of the following results:

- **The workload is suitable for ARP**. ARP automatically sets the adaptive threshold to higher than 10% of the maximum encryption percentage seen during the evaluation period. ARP also continues statistics collection and creates periodic ARP snapshots.
- **The workload is unsuitable for ARP**. ARP automatically sets the adaptive threshold to the maximum encryption percentage seen during the evaluation period. ARP also continues statistics collection and creates periodic ARP snapshots, but the system ultimately recommends disabling ARP on the volume.

Determine evaluation results

After the evaluation period ends, ARP automatically sets the adaptive threshold based on the evaluation results.

You can determine the evaluation results by running the following command. Volume suitability is indicated in the `Block device detection status` field:

```
security anti-ransomware volume show  -vserver <svm_name> -volume
<volume_name>
```

Example response:

```
Vserver Name                                : vs1
Volume Name                                 : v1
State                                       : enabled
Attack Probability                          : none
Attack Timeline                             : -
Number of Attacks                           : -
Attack Detected By                          : -
Block device detection status               : Active_suitable_workload

Block device evaluation start time :  5/16/2025 01:49:01
```

You can also show the value threshold adopted as a result of the evaluation:

```
security anti-ransomware volume attack-detection-parameters show -vserver
<svm_name> -volume <volume_name>
```

Example response:

```
                                  Vserver Name : vs_1

                                   Volume Name : vm_2

Block Device Auto Learned Encryption Threshold : 10
...
```

Pause ONTAP Autonomous Ransomware Protection to exclude workload events from analysis

If you are expecting unusual workload events, you can temporarily suspend and resume Autonomous Ransomware Protection (ARP) analysis at any time.

Beginning with ONTAP 9.13.1, you can enable multi-admin verification (MAV) so that two or more authenticated user admins are required to pause the ARP.

Learn more about MAV.

About this task

During an ARP pause, no events or actions for new writes are logged; however, the analytics operation continues for earlier logs in the background.

> Do not use the ARP disable function to pause analytics. Doing so disables ARP on the volume and all the existing information around learned workload behavior is lost. This would require a restart of the learning period.

Steps

You can use System Manager or the ONTAP CLI to pause ARP.

System Manager

1. Select **Storage > Volumes** and then select the volume where you want to pause ARP.
2. In the **Security** tab of the Volumes overview, select **Pause anti-ransomware** in the **Anti-ransomware** box.

   > Beginning with ONTAP 9.13.1, if you are using MAV to protect your ARP settings, the pause operation prompts you to obtain the approval of one or more additional administrators. Approval must be received from all administrators associated with the MAV approval group or the operation will fail.

3. To resume monitoring, select **Resume anti-ransomware**.

CLI

1. Pause ARP on a volume:

```
security anti-ransomware volume pause -vserver <svm_name> -volume
<vol_name>
```

2. To resume processing, use the `resume` command:

```
security anti-ransomware volume resume -vserver <svm_name> -volume
<vol_name>
```

   Learn more about `security anti-ransomware volume` in the ONTAP command reference.

3. If you are using MAV (available with ARP beginning with ONTAP 9.13.1) to protect your ARP settings, the pause operation prompts you to obtain the approval of one or more additional administrators. Approval must be received from all administrators associated with the MAV approval group or the operation will fail.

   If you are using MAV and an expected pause operation needs additional approvals, each MAV group approver does the following:

   a. Show the request:

```
security multi-admin-verify request show
```

   b. Approve the request:

```
security multi-admin-verify request approve -index[<number
returned from show request>]
```

   The response for the last group approver indicates that the volume has been modified and the state of ARP is paused.

If you are using MAV and you are a MAV group approver, you can reject a pause operation request:

```
security multi-admin-verify request veto -index[<number returned
from show request>]
```

Learn more about `security multi-admin-verify request` in the ONTAP command reference.

Manage ONTAP Autonomous Ransomware Protection attack detection parameters

Beginning with ONTAP 9.11.1, you can modify the parameters for ransomware detection on a specific volume with Autonomous Ransomware Protection enabled and report a known surge as normal file activity. Adjusting detection parameters helps improve the accuracy of reporting based on your specific volume workload.

How attack detection works

When Autonomous Ransomware Protection (ARP) is in a learning or evaluation mode, it develops baseline values for volume behaviors. These include entropy, file extensions, and, beginning with ONTAP 9.11.1, IOPS. These baselines are used to evaluate ransomware threats. For more information about these criteria, see what ARP detects.

Certain volumes and workloads require different detection parameters. For example, your ARP-enabled volume may host numerous types of file extensions, in which case you may want to modify the threshold count for never-before-seen file extensions to a number greater than the default of 20 or disable warnings based on never-before-seen file extensions. Beginning with ONTAP 9.11.1, you can modify the attack detection parameters so they better fit your specific workloads.

Beginning with ONTAP 9.14.1, you can configure alerts when ARP observes a new file extension and when ARP creates a snapshot. For more information, see Configure ARP alerts.

Attack detection in NAS environments

In ONTAP 9.10.1, ARP issues a warning if it detects both of the following conditions:

- More than 20 files with file extensions not previously observed in the volume
- High entropy data

Beginning with ONTAP 9.11.1, ARP issues a threat warning if *only* one condition is met. For example, if more than 20 files with file extensions that have not previously been observed in the volume are observed within a 24-hour period, ARP will categorize this as a threat *regardless* of observed entropy. The 24-hour and 20-file values are defaults, which can be modified.

> To reduce high numbers of false positive alerts, go to **Storage > Volumes > Security > Configure workload characteristics** and disable **Monitor new file types**. This setting is disabled by default in ONTAP 9.14.1 P7, 9.15.1 P1, 9.16.1, and later.

Attack detection in SAN environments

Beginning with ONTAP 9.17.1, ARP issues a warning if it detects high encryption rates that exceed an automatically learned threshold. This threshold is established after an evaluation period but can be modified.

Modify attack detection parameters

Depending on the expected behaviors of your ARP-enabled volume, you might want to modify the attack detection parameters.

Steps

1. View the existing attack detection parameters:

   ```
   security anti-ransomware volume attack-detection-parameters show
   -vserver <svm_name> -volume <volume_name>
   ```

   ```
   security anti-ransomware volume attack-detection-parameters show
   -vserver vs1 -volume vol1
                                                Vserver Name : vs1
                                                 Volume Name : vol1
               Block Device Auto Learned Encryption Threshold : 10
                Is Detection Based on High Entropy Data Rate? : true
      Is Detection Based on Never Seen before File Extension? : true
                     Is Detection Based on File Create Rate? : true
                     Is Detection Based on File Rename Rate? : true
                     Is Detection Based on File Delete Rate? : true
               Is Detection Relaxing Popular File Extensions? : true
                    High Entropy Data Surge Notify Percentage : 100
                     File Create Rate Surge Notify Percentage : 100
                     File Rename Rate Surge Notify Percentage : 100
                     File Delete Rate Surge Notify Percentage : 100
    Never Seen before File Extensions Count Notify Threshold : 20
          Never Seen before File Extensions Duration in Hour : 24
   ```

2. All the fields shown are modifiable with boolean or integer values. To modify a field, use the `security anti-ransomware volume attack-detection-parameters modify` command.

   Learn more about `security anti-ransomware volume attack-detection-parameters modify` in the ONTAP command reference.

Report known surges

ARP continues to modify baseline values for detection parameters even when active. If you know of surges in your volume activity, either one-time surges or a surge that is characteristic of a new normal, you should report them as safe. Manually reporting these surges as safe helps to improve the accuracy of ARP's threat assessments.

Report a one-time surge

1. If a one-time surge is occurring under known circumstances and you want ARP to report a similar surge in future circumstances, clear the surge from the workload behavior:

```
security anti-ransomware volume workload-behavior clear-surge -vserver
<svm_name> -volume <volume_name>
```

Learn more about `security anti-ransomware volume workload-behavior clear-surge` in the ONTAP command reference.

Modify baseline surge

1. If a reported surge should be considered normal application behavior, report the surge as such to modify the baseline surge value.

   ```
   security anti-ransomware volume workload-behavior update-baseline-from-surge
   -vserver <svm_name> -volume <volume_name>
   ```

   Learn more about `security anti-ransomware volume workload-behavior update-baseline-from-surge` in the ONTAP command reference.

Configure ARP alerts

Beginning with ONTAP 9.14.1, ARP allows you to specify alerts for two ARP events:

- Observation of new file extension on a volume
- Creation of an ARP snapshot

Alerts for these two events can be set on individual volumes or for the entire SVM. If you enable alerts for the SVM, the alert settings are inherited only by volumes created after you enable alert. By default, alerts are not enabled on any volume.

Event alerts can be controlled with multi-admin verification. For more information, see Multi-admin verification with volumes protected with ARP.

Steps

You can use System Manager or the ONTAP CLI to set alerts for ARP events.

System Manager

Set alerts for a volume

1. Navigate to **Volumes**. Select the individual volume for which you want to modify settings.
2. Select the **Security** tab then **Event severity settings**.
3. To receive alerts for **New file extension detected** and **Ransomware snapshot created**, select the dropdown menu under the **Severity** heading. Modify the setting from **Don’t generate event** to **Notice**.
4. Select **Save**.

Set alerts for an SVM

1. Navigate to **Storage VM** then select the SVM for which you want to enable settings.
2. Under the **Security** heading, locate the **Anti-ransomware** card. Select ⋮ then **Edit Ransomware Event Severity**.
3. To receive alerts for **New file extension detected** and **Ransomware snapshot created**, select the dropdown menu under the **Severity** heading. Modify the setting from **Don’t generate event** to **Notice**.
4. Select **Save**.

CLI

Set alerts for a volume

- To set alerts for a new file-extension:

  ```
  security anti-ransomware volume event-log modify -vserver <svm_name> -is
  -enabled-on-new-file-extension-seen true
  ```

- To set alerts for the creation of an ARP snapshot:

  ```
  security anti-ransomware volume event-log modify -vserver <svm_name> -is
  -enabled-on-snapshot-copy-creation true
  ```

- Confirm your settings with the `anti-ransomware volume event-log show` command.

Set alerts for an SVM

- To set alerts for a new file-extension:

  ```
  security anti-ransomware vserver event-log modify -vserver <svm_name> -is
  -enabled-on-new-file-extension-seen true
  ```

- To set alerts for the creation of an ARP snapshot:

  ```
  security anti-ransomware vserver event-log modify -vserver <svm_name> -is
  -enabled-on-snapshot-copy-creation true
  ```

- Confirm your settings with the `security anti-ransomware vserver event-log show` command.

Learn more about `security anti-ransomware vserver event-log` commands in the ONTAP command reference.

Respond to abnormal activity detected by ONTAP ARP

When Autonomous Ransomware Protection (ARP) detects abnormal activity in a protected volume, it issues a warning. You should evaluate the notification to determine whether the activity is acceptable (false positive) or whether an attack seems malicious. After you categorize the attack, you can clear the warning and notices about suspected files.

When you categorize an attack, ARP snapshots are either retained for an abbreviated period initiated by the categorization operation (ONTAP 9.16.1 and later), or deleted instantly (ONTAP 9.15.1 and earlier).

> Beginning with ONTAP 9.11.1, you can modify the retention settings for ARP snapshots.

About this task

ARP displays a list of suspected files when it detects any combination of high data entropy, abnormal volume activity with data encryption, and unusual file extensions. Beginning with ONTAP 9.17.1 for both NAS and SAN environments, details of entropy spikes are also reported on the Anti-ransomware page in System Manager.

When an ARP warning notification is issued, respond by designating the activity in one of two ways:

- **False positive**

  The identified file type or entropy spike is expected in your workload and can be ignored.

- **Potential ransomware attack**

  The identified file type or entropy spike is unexpected in your workload and should be treated as a potential attack.

Normal monitoring resumes after you update with your decision and clear the ARP notifications. ARP records your evaluation to the threat assessment profile, using your choice to monitor subsequent file activities.

In the case of a suspected attack, you must determine whether it is an attack, respond to it if it is, and restore protected data before clearing the notices. Learn more about how to recover from a ransomware attack.

> If you restore an entire volume, there are no notices to clear.

Before you begin

ARP must be actively protecting a volume and not in a learning or evaluation mode.

Steps

You can use System Manager or the ONTAP CLI to respond to abnormal activity.

System Manager

1. When you receive an "abnormal activity" notification, follow the link. Alternatively, navigate to the **Security** tab of the **Volumes** overview.

   Warnings are displayed in the **Overview** pane of the **Events** menu.

2. In the **Security** tab, review the suspected file types or entropy spikes report.
   - For suspected files, examine each file type in the **Suspected File Types** dialog box and mark each individually.
   - For entropy spikes, examine the entropy report.
3. Record your response:

If you select this value…	Take this action…
False Positive	1. Do one of the following: ◦ For file type warnings, select **Update and Clear Suspect File Types**. ◦ For entropy spikes, select **Mark as false positive**. These actions clear warning notices about suspected files or activity. ARP then resumes normal monitoring of the volume. For ARP/AI in ONTAP 9.16.1 and later, ARP snapshots are automatically deleted after an abbreviated retention period triggered by the categorization operation. For ONTAP 9.15.1 and earlier, related ARP snapshots are automatically deleted after you clear suspected file types. ⓘ Beginning with ONTAP 9.13.1, if you are using MAV to protect your ARP settings, the clear-suspect operation prompts you to obtain the approval of one or more additional administrators. Approval must be received from all administrators associated with the MAV approval group or the operation will fail.

Potential Ransomware Attack	1. Respond to the attack: ◦ For file type warnings, mark selected files as **Potential ransomware attack** and restore protected data. ◦ For entropy spikes that indicate an attack, select **Mark as potential ransomware attack** and restore protected data. 2. After data restoration is complete, record your decision and resume normal ARP monitoring: ◦ For file type warnings, select **Update and Clear Suspect File Types**. ◦ For entropy spikes, select **Mark as potential ransomware attack** and select **Save and dismiss**. ⓘ There are no suspected file type notices to clear if you've restored an entire volume. Recording your decision clears the attack report. For ARP/AI in ONTAP 9.16.1 and later, ARP snapshots are automatically deleted after an abbreviated retention period triggered by the categorization operation. For ONTAP 9.15.1 and earlier, after you restore a volume the ARP snapshots are automatically deleted.

CLI

1. When you receive a notification of a suspected ransomware attack, verify the time and severity of the attack:

```
security anti-ransomware volume show -vserver <svm_name> -volume
<vol_name>
```

Sample output:

```
Vserver Name: vs0
Volume Name: vol1
State: enabled
Attack Probability: moderate
Attack Timeline: 5/12/2025 01:03:23
Number of Attacks: 1
Attack Detected By: encryption_percentage_analysis
```

You can also check EMS messages:

```
event log show -message-name callhome.arw.activity.seen
```

2. Generate an attack report and note the output location:

```
security anti-ransomware volume attack generate-report -vserver
<svm_name> -volume <vol_name> -dest-path
<[svm_name]:[junction_path/sub_dir_name]>
```

Sample command:

```
security anti-ransomware volume attack generate-report -vserver vs0
-volume vol1 -dest-path vs0:vol1
```

Sample output:

```
Report "report_file_vs0_vol1_14-09-2021_01-21-08" available at path
"vs0:vol1/"
```

3. View the report on an admin client system. For example:

```
cat report_file_vs0_vol1_14-09-2021_01-21-08
```

4. Take one of the following actions based on your evaluation of the file extensions or entropy spikes:

    - False positive

      Run one of the following commands to record your decision and resume normal Autonomous Ransomware Protection monitoring:

        - For file extensions:

          ```
          anti-ransomware volume attack clear-suspect -vserver
          <svm_name> -volume <vol_name> [<extension_identifiers>] -false
          -positive true
          ```

          Use the following optional parameter to identify only specific extensions as false positives:

            - `[-extension <text>, … ]`: File extensions

        - For entropy spikes:

          ```
          security anti-ransomware volume attack clear-suspect -vserver
          <svm_name> -volume <vol_name> -start-time <MM/DD/YYYY
          HH:MM:SS> -end-time <MM/DD/YYYY HH:MM:SS> -false-positive true
          ```

    - Potential ransomware attack

Respond to the attack and recover data from the ARP-created backup snapshot. After the data is recovered, run one of the following commands to record your decision and resume normal ARP monitoring:

- For file extensions:

```
anti-ransomware volume attack clear-suspect -vserver
<svm_name> -volume <vol_name> [<extension identifiers>] -false
-positive false
```

  Use the following optional parameter to identify only specific extensions as potential ransomware:

  - `[-extension <text>, … ]`: File extension

- For entropy spikes:

```
security anti-ransomware volume attack clear-suspect -vserver
<svm_name> -volume <vol_name> -start-time <MM/DD/YYYY
HH:MM:SS> -end-time <MM/DD/YYYY HH:MM:SS> -false-positive
false
```

This `clear-suspect` operation clears the attack report. There are no suspected file type notices to clear if you restored an entire volume. For ARP/AI in ONTAP 9.16.1 and later, ARP snapshots are automatically deleted after an abbreviated retention period triggered by the categorization operation. For ONTAP 9.15.1 and earlier, ARP snapshots are automatically deleted after you restore a volume or clear a suspected event.

5. If you are using MAV and an expected `clear-suspect` operation needs additional approvals, each MAV group approver must:

   a. Show the request:

```
security multi-admin-verify request show
```

   b. Approve the request to resume normal anti-ransomware monitoring:

```
security multi-admin-verify request approve -index[<number
returned from show request>]
```

   The response for the last group approver indicates that the volume has been modified and a false positive is recorded.

6. If you are using MAV and you are a MAV group approver, you can also reject a clear-suspect request:

```
security multi-admin-verify request veto -index[<number returned
from show request>]
```

Restore data from ONTAP ARP snapshots after a ransomware attack

Autonomous Ransomware Protection (ARP) creates snapshots to protect against a potential ransomware threat. You can use one of these ARP snapshots or another snapshot of your volume to restore data.

About this task

The ARP creates snapshots with one of the following prepended names:

- `Anti_ransomware_periodic_backup`: Used in ONTAP 9.17.1 and later for snapshots created at regular intervals. For example, `Anti_ransomware_periodic_backup.2025-06-01_1248`.
- `Anti_ransomware_backup`: Used in ONTAP 9.16.1 and earlier with snapshots that are created in response to abnormalities. For example, `Anti_ransomware_backup.2022-12-20_1248`.

To restore from a snapshot other than the `Anti_ransomware` snapshot after a system attack is identified, you must first release the ARP snapshot.

If no system attack is reported, you must first restore from the `Anti_ransomware` snapshot then complete a subsequent restoration of the volume from the snapshot you choose.

> If the ARP-protected volume is part of a SnapMirror relationship, you'll need to manually update all mirror copies of the volume after restoring it from a snapshot. If you skip this step, the mirror copies might become unusable and need to be deleted and recreated.

Before you begin

You must mark the attack as a potential ransomware attack before restoring data from a snapshot.

Steps

You can use System Manager or the ONTAP CLI to restore your data.

System Manager

Restore after a system attack

1. To restore from the ARP snapshot, skip to step two. To restore from an earlier snapshot, you must first release the lock on the ARP snapshot.
   a. Select **Storage > Volumes**.
   b. Select **Security** then **View Suspected File Types**.
   c. Mark the files as "Potential ransomware attack".
   d. Select **Update** and **Clear Suspect File Types**.
2. Display the snapshots in volumes:

   Select **Storage > Volumes**, then select the volume and **Snapshot Copies**.
3. Select ⋮ next to the snapshot you want to restore then **Restore**.

Restore if a system attack was not identified

1. Display the snapshots in volumes:

   Select **Storage > Volumes**, then select the volume and **Snapshot Copies**.
2. Select ⋮ then choose the `Anti_ransomware` snapshot.
3. Select **Restore**.
4. Return to the **Snapshot Copies** menu, then choose the snapshot you want to use. Select **Restore**.

CLI

Restore after a system attack

To restore from the ARP snapshot, skip to step two. To restore data from earlier snapshots, you must release the lock on the ARP snapshot.

> ⓘ It is only necessary to release the anti-ransomware Snaplock before restoring from earlier snapshots if you are using the `volume snapshot restore` command as outlined below. If you are restoring data using FlexClone, Single File Snap Restore, or other methods, this is not necessary.

1. Mark the attack as a potential ransomware attack (`-false-positive false`) and clear suspect files (`clear-suspect`):

   ```
   anti-ransomware volume attack clear-suspect -vserver <svm_name>
   -volume <vol_name> [<extension identifiers>] -false-positive false
   ```

   Use one of the following parameters to identify the extensions:
   - `[-seq-no integer]`: Sequence number of the file in the suspect list.
   - `[-extension text, … ]`: File extensions
   - `[-start-time date_time -end-time date_time]`: Starting and ending times for the range of files to be cleared, in the form "MM/DD/YYYY HH:MM:SS".

2. List the snapshots in a volume:

```
volume snapshot show -vserver <SVM> -volume <volume>
```

The following example shows the snapshot in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1

Vserver Volume Snapshot                State    Size  Total% Used%
------- ------ ---------- ----------- ------   -----  ------ -----
vs1     vol1   hourly.2013-01-25_0005  valid   224KB     0%    0%
               daily.2013-01-25_0010   valid   92KB      0%    0%
               hourly.2013-01-25_0105  valid   228KB     0%    0%
               hourly.2013-01-25_0205  valid   236KB     0%    0%
               hourly.2013-01-25_0305  valid   244KB     0%    0%
               hourly.2013-01-25_0405  valid   244KB     0%    0%
               hourly.2013-01-25_0505  valid   244KB     0%    0%

7 entries were displayed.
```

3. Restore the contents of a volume from a snapshot:

```
volume snapshot restore -vserver <SVM> -volume <volume> -snapshot
<snapshot>
```

The following example restores the contents of `vol1`:

```
cluster1::> volume snapshot restore -vserver vs0 -volume vol1
-snapshot daily.2013-01-25_0010
```

Restore if a system attack was not identified

1. List the snapshots in a volume:

```
volume snapshot show -vserver <SVM> -volume <volume>
```

The following example shows the snapshot in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1

Vserver Volume Snapshot                State    Size  Total% Used%
------- ------ ---------- ----------- ------   -----  ------ -----
vs1     vol1   hourly.2013-01-25_0005  valid   224KB     0%    0%
               daily.2013-01-25_0010   valid   92KB      0%    0%
               hourly.2013-01-25_0105  valid   228KB     0%    0%
               hourly.2013-01-25_0205  valid   236KB     0%    0%
               hourly.2013-01-25_0305  valid   244KB     0%    0%
               hourly.2013-01-25_0405  valid   244KB     0%    0%
               hourly.2013-01-25_0505  valid   244KB     0%    0%

7 entries were displayed.
```

2. Restore the contents of a volume from a snapshot:

```
volume snapshot restore -vserver <SVM> -volume <volume> -snapshot
<snapshot>
```

The following example restores the contents of `vol1`:

```
cluster1::> volume snapshot restore -vserver vs0 -volume vol1
-snapshot daily.2013-01-25_0010
```

Learn more about `volume snapshot` in the ONTAP command reference.

Adjust settings for automatically generated ARP snapshots

Beginning with ONTAP 9.11.1, you can use the CLI to control the retention settings for Autonomous Ransomware Protection (ARP) snapshots that are automatically generated in response to suspected ransomware attacks.

Before you begin

You can only modify ARP snapshots options on a node SVM and not on other SVM types.

Steps

1. Show all current ARP snapshot settings:

```
options -option-name arw*
```

2. Show selected current ARP snapshot settings:

```
options -option-name <arw_setting_name>
```

3. Modify ARP snapshot settings:

```
options -option-name <arw_setting_name> -option-value
<arw_setting_value>
```

The following settings are modifiable:

> Some of the commands described are deprecated as of ONTAP 9.17.1. Commands introduced in ONTAP 9.17.1 support both NAS and SAN environments.

Setting	Description	Supported versions
`arw.snap.max.count`	Specifies the maximum number of ARP snapshots that can exist in a volume at any given time. Older copies are deleted to ensure that the total number of ARP snapshots is within this specified limit.	ONTAP 9.11.1 and later
`arw.snap.create.interval.hours`	Specifies the interval *in hours* between ARP snapshots. A new ARP snapshot is created when a data entropy-based attack is suspected and the most recently created ARP snapshot is older than the specified interval.	ONTAP 9.11.1 and later
`arw.snap.normal.retain.interval.hours`	Specifies the duration *in hours* for which an ARP snapshot is retained. When an ARP snapshot reaches the retention threshold, it is deleted.	• ONTAP 9.11.1 to ONTAP 9.16.1 • Deprecated in ONTAP 9.17.1 and later

Setting	Description	Supported versions
`arw.snap.max.retain.interval.days`	Specifies the maximum duration *in days* for which an ARP snapshot can be retained. Any ARP snapshot older than this duration is deleted when there is no attack reported on the volume. The maximum retention interval for ARP snapshots is ignored if a moderate threat is detected. The ARP snapshot created in response to the threat is retained until you have responded to the threat. When you mark a threat as a false positive, ONTAP will delete the ARP snapshots for the volume.	• ONTAP 9.11.1 to ONTAP 9.16.1 • Deprecated in ONTAP 9.17.1 and later
`arw.snap.create.interval.hours.post.max.count`	Specifies the interval *in hours* between ARP snapshots when the volume already contains the maximum number of ARP snapshots. When the maximum number is reached, an ARP snapshot is deleted to make room for a new copy. The new ARP snapshot creation speed can be reduced to retain the older copy using this option. If the volume already contains the maximum number of ARP snapshots, the interval specified in this option is used for the next ARP snapshot creation, instead of `arw.snap.create.interval.hours`.	• ONTAP 9.11.1 to 9.16.1 • Deprecated in ONTAP 9.17.1 and later
`arw.snap.low.encryption.retain.duration.hours`	Specifies the retention duration *in hours* for ARP snapshots created during periods of low encryption activity.	• ONTAP 9.17.1 and later
`arw.snap.new.extns.interval.hours`	Specifies the interval *in hours* between the ARP snapshots created when a new file extension is detected. A new ARP snapshot is created when a new file extension is observed; the previous snapshot created upon observing a new file extension is older than this specified interval. On a workload that frequently creates new file extensions, this interval helps control the frequency of the ARP snapshots. This option exists independent of `arw.snap.create.interval.hours`, which specifies the interval for data entropy-based ARP snapshots.	• ONTAP 9.11.1 to ONTAP 9.16.1 • Deprecated in ONTAP 9.17.1 and later
`arw.snap.retain.hours.after.clear.suspect.false.alert`	Specifies the interval *in hours* an ARP snapshot is retained as a precaution after an attack incident is marked as a false positive by the administrator. After this precautionary retention period expires, the snapshot may be deleted according to the standard retention duration defined by the options `arw.snap.normal.retain.interval.hours` and `arw.snap.max.retain.interval.days`.	• ONTAP 9.16.1 and later

Setting	Description	Supported versions
`arw.snap.retain.hours.after.clear.suspect.real.attack`	Specifies the interval *in hours* an ARP snapshot is retained as a precaution after an attack incident is marked as a real attack by the administrator. After this precautionary retention period expires, the snapshot may be deleted according to the standard retention duration defined by the options `arw.snap.normal.retain.interval.hours` and `arw.snap.max.retain.interval.days`.	• ONTAP 9.16.1 and later
`arw.snap.surge.interval.days`	Specifies the interval *in days* between ARP snapshots created in response to IO surges. ONTAP creates an ARP snapshot surge copy when there's a surge in IO traffic and the last created ARP snapshot is older than this specified interval. This option also specifies retention period *in day* for an ARP surge snapshot.	ONTAP 9.11.1 and later
`arw.high.encryption.alert.enabled`	Enables alerts for high levels of encryption. When this option is set to `on` (default), ONTAP sends an alert when the percentage of encryption exceeds the threshold specified in `arw.high.encryption.percentage.threshold`.	ONTAP 9.17.1 and later
`arw.high.encryption.percentage.threshold`	Specifies the maximum percentage of encryption for a volume. If the percentage of encryption is more than this threshold, ONTAP handles the increase as an attack and creates an ARP snapshot. `arw.high.encryption.alert.enabled` must be set to `on` for this option to take effect.	ONTAP 9.17.1 and later
`arw.snap.high.encryption.retain.duration.hours`	Specifies the retention duration interval *in hours* for snapshots created during a high encryption threshold event.	ONTAP 9.17.1 and later

4. If you are using ARP with a SAN environment, you can also modify the following evaluation period settings:

Setting	Description	Supported versions
`arw.block_device.auto.learn.threshold.min_value`	Specifies the minimum encryption threshold percentage value during the auto-learn phase of evaluation for block devices.	ONTAP 9.17.1 and later
`arw.block_device.auto.learn.threshold.max_value`	Specifies the maximum encryption threshold percentage value during the auto-learn phase of evaluation for block devices.	ONTAP 9.17.1 and later
`arw.block_device.evaluation.phase.min_hours`	Specifies the minimum interval *in hours* the evaluation phase must run before the encryption threshold is set.	ONTAP 9.17.1 and later

Setting	Description	Supported versions
arw.block_device.evaluation.phase.max_hours	Specifies the maximum interval *in hours* the evaluation phase must run before the encryption threshold is set.	ONTAP 9.17.1 and later
arw.block_device.evaluation.phase.min_data_ingest_size_GB	Specifies the minimum amount of data *in GB* that must be ingested during the evaluation phase before the encryption threshold is set.	ONTAP 9.17.1 and later
arw.block_device.evaluation.phase.alert.enabled	Specifies whether alerts are enabled for the evaluation phase of ARP on block devices. Default value is `True`.	ONTAP 9.17.1 and later
arw.block_device.evaluation.phase.alert.threshold	Specifies the threshold percentage during the evaluation phase of ARP on block devices. If the percentage of encryption exceeds this threshold, an alert is triggered.	ONTAP 9.17.1 and later

Virus protection with Vscan

Learn about antivirus configuration with ONTAP Vscan

Vscan is an antivirus scanning solution developed by NetApp that allows customers to protect their data from being compromised by viruses or other malicious code.

Vscan performs virus scans when clients access files over SMB. You can configure Vscan to scan on-demand or on a schedule. You can interact with Vscan using the ONTAP command-line interface (CLI) or ONTAP application programming interfaces (APIs).

Related information

Vscan partner solutions

About NetApp antivirus protection

Learn about NetApp virus scanning with ONTAP Vscan

Vscan is an antivirus scanning solution developed by NetApp that allows customers to protect their data from being compromised by viruses or other malicious code. It combines partner-provided antivirus software with ONTAP features to give customers the flexibility they need to manage file scanning.

How virus scanning works

Storage systems offload scanning operations to external servers hosting antivirus software from third-party vendors.

Based on the active scanning mode, ONTAP sends scan requests when clients access files over SMB (on-access) or access files in specific locations, on a schedule or immediately (on-demand).

- You can use *on-access scanning* to check for viruses when clients open, read, rename, or close files over SMB. File operations are suspended until the external server reports the scan status of the file. If the file has already been scanned, ONTAP allows the file operation. Otherwise, it requests a scan from the server.

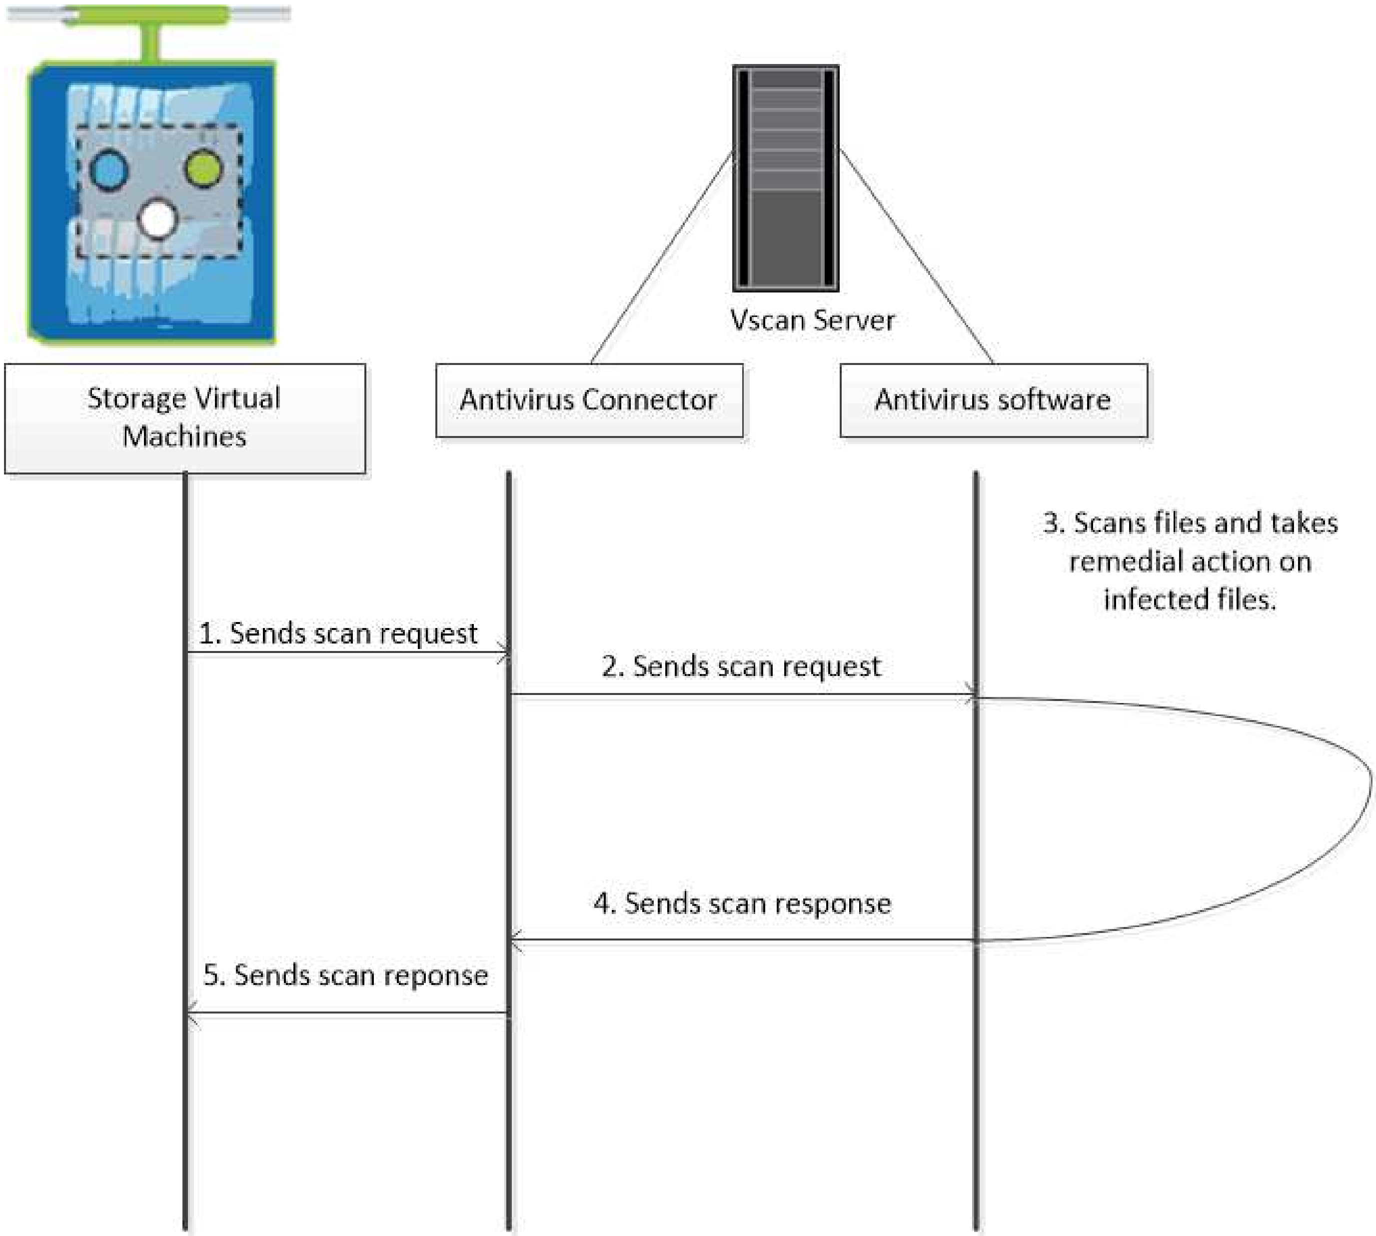
  On-access scanning is not supported for NFS.

- You can use *on-demand scanning* to check files for viruses immediately or on a schedule. We recommend that on-demand scans run only in off-peak hours to avoid overloading existing AV infrastructure, which is normally sized for on-access scanning. The external server updates the scan status of checked files, so that file-access latency is reduced over SMB. If there were file modifications or software version updates, it requests a new file scan from the external server.

  You can use on-demand scanning for any path in the SVM namespace, even for volumes that are exported only through NFS.

You typically enable both on-access and on-demand scanning modes on an SVM. In either mode, the antivirus software takes remedial action on infected files based on your software settings.

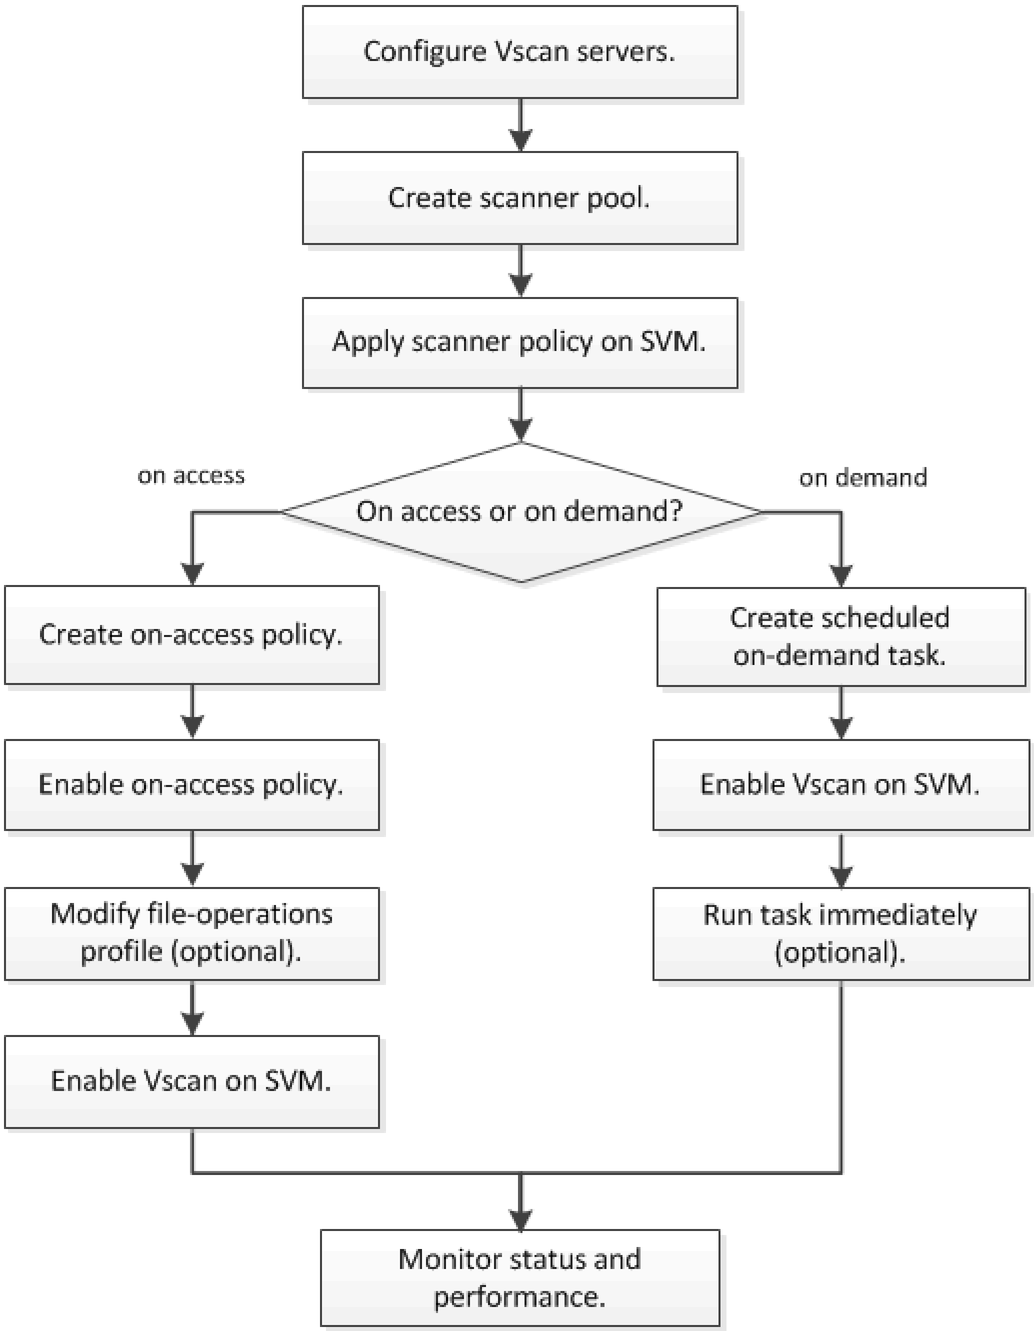
The ONTAP Antivirus Connector, provided by NetApp and installed on the external server, handles communication between the storage system and the antivirus software.



Virus scanning workflow with ONTAP Vscan

You must create a scanner pool and apply a scanner policy before you can enable scanning. You typically enable both on-access and on-demand scanning modes on an SVM.

> ⓘ You must have completed the CIFS configuration.



To create an on-demand task, there must be at least one on-access policy enabled. It can be the default policy or a user created on-access policy.

Next steps

- Create a scanner pool on a single cluster
- Apply a scanner policy on a single cluster
- Create an on-access policy

Antivirus architecture with ONTAP Vscan

The NetApp antivirus architecture consists of Vscan server software and associated settings.

Vscan server software

You must install this software on the Vscan server.

- **ONTAP Antivirus Connector**

  This is NetApp-provided software that handles scan request and response communication between the SVMs and antivirus software. It can run on a virtual machine, but for best performance use a physical machine. You can download this software from the NetApp Support Site (requires login).

- **Antivirus software**

  This is partner-provided software that scans files for viruses or other malicious code. You specify the remedial actions to be taken on infected files when you configure the software.

Vscan software settings

You must configure these software settings on the Vscan server.

- **Scanner pool**

  This setting defines the Vscan servers and privileged users that can connect to SVMs. It also defines a scan request timeout period, after which the scan request is sent to an alternative Vscan server if one is available.

  > You should set the timeout period in the antivirus software on the Vscan server to five seconds less than the scanner-pool scan-request timeout period. This will avoid situations in which file access is delayed or denied altogether because the timeout period on the software is greater than the timeout period for the scan request.

- **Privileged user**

  This setting is a domain user account that a Vscan server uses to connect to the SVM. The account must exist in the list of privileged users in the scanner pool.

- **Scanner policy**

  This setting determines whether a scanner pool is active. Scanner policies are system-defined, so you cannot create custom scanner policies. Only these three policies are available:

  - `Primary` specifies that the scanner pool is active.
  - `Secondary` specifies that the scanner pool is active, only when none of the Vscan servers in the primary scanner pool are connected.
  - `Idle` specifies that the scanner pool is inactive.

- **On-access policy**

  This setting defines the scope of an on-access scan. You can specify the maximum file size to scan, file extensions and paths to include in the scan, and file extensions and paths to exclude from the scan.

  By default, only read-write volumes are scanned. You can specify filters that enable scanning of read-only volumes or that restrict scanning to files opened with execute access:

  - `scan-ro-volume` enables scanning of read-only volumes.

◦ `scan-execute-access` restricts scanning to files opened with execute access.

> “Execute access” is different from “execute permission.” A given client will have “execute access” on an executable file only if the file was opened with “execute intent.”

You can set the `scan-mandatory` option to off to specify that file access is allowed when no Vscan servers are available for virus scanning. Within on-access mode you can choose from these two mutually-exclusive options:

◦ Mandatory: With this option, Vscan tries to deliver the scan request to the server until the timeout period expires. If the scan request is not accepted by the server, then the client access request is denied.

◦ Non-Mandatory: With this option, Vscan always allows client access, whether or not a Vscan server was available for virus scanning.

- **On-demand task**

  This setting defines the scope of an on-demand scan. You can specify the maximum file size to scan, file extensions and paths to include in the scan, and file extensions and paths to exclude from the scan. Files in subdirectories are scanned by default.

  You use a cron schedule to specify when the task runs. You can use the `vserver vscan on-demand-task run` command to run the task immediately. Learn more about `vserver vscan on-demand-task run` in the ONTAP command reference.

- **Vscan file-operations profile (on-access scanning only)**

  The `vscan-fileop-profile` parameter for the `vserver cifs share create` command defines which SMB file operations trigger virus scanning. By default, the parameter is set to `standard`, which is NetApp best practice. You can adjust this parameter as necessary when you create or modify an SMB share:

  ◦ `no-scan` specifies that virus scans are never triggered for the share.

  ◦ `standard` specifies that virus scans are triggered by open, close, and rename operations.

  ◦ `strict` specifies that virus scans are triggered by open, read, close, and rename operations.

  The `strict` profile provides enhanced security for situations in which multiple clients access a file simultaneously. If one client closes a file after writing a virus to it, and the same file remains open on a second client, `strict` ensures that a read operation on the second client triggers a scan before the file is closed.

  You should be careful to restrict the `strict` profile to shares containing files that you anticipate will be accessed simultaneously. Since this profile generates more scan requests, it may impact performance.

  ◦ `writes-only` specifies that virus scans are triggered only when modified files are closed.

  Since `writes-only` generates fewer scan requests, it typically improves performance.

  If you use this profile, the scanner must be configured to delete or quarantine unrepairable infected files, so they cannot be accessed. If, for example, a client closes a file after writing a virus to it, and the file is not repaired, deleted, or quarantined, any client that accesses the file `without` writing to it will be infected.

> If a client application performs a rename operation, the file is closed with the new name and is not scanned. If such operations pose a security concern in your environment, you should use the `standard` or `strict` profile.

Learn more about `vserver cifs share create` in the ONTAP command reference.

Learn about ONTAP Vscan partner solutions

NetApp collaborates with Trellix, Symantec, Trend Micro, Sentinel One, Deep Instinct, and OPSWAT to deliver industry-leading anti-malware and anti-virus solutions that build upon ONTAP Vscan technology. These solutions help you scan files for malware and remediate any affected files.

As shown in the table below, interoperability details for Trellix, Symantec, and Trend Micro are maintained on the NetApp Interoperability Matrix. Interoperability details for Trellix, Symantec, Deep Instinct, and OPSWAT can also be found on the partner websites. Interoperability details for Sentinel One, Deep Instinct, OPSWAT, and other new partners will be maintained by the partner on their websites.

Partner	Solution documentation	Interoperability details
Trellix (Formerly McAfee)	Trellix Product Documentation	• NetApp Interoperability Matrix Tool • Supported platforms for Endpoint Security Storage Protection (trellix.com)
Symantec	Symantec Protection Engine 9.0.0	• NetApp Interoperability Matrix Tool • Support Matrix for Partner Devices Certified with Symantec Protection Engine (SPE) for Network Attached Storage (NAS) 9.x.x • Support Matrix for Partner Devices Certified with Symantec Protection Engine (SPE) for Network Attached Storage (NAS) 8.x (broadcom.com)
Trend Micro	Trend Micro ServerProtect for Storage 6.0 Getting Started Guide	NetApp Interoperability Matrix Tool

OPSWAT	OPSWAT MetaDefender Storage Security • MetaDefender Storage Security Integration with NetApp • OPSWAT Partner Page • Integration Solution Brief	N/A

Vscan server installation and configuration

ONTAP Vscan server installation and configuration

Set up one or more Vscan servers to ensure that files on your system are scanned for viruses. Follow the instructions provided by your vendor to install and configure the antivirus software on the server.

Follow the instructions in the README file provided by NetApp to install and configure the ONTAP Antivirus Connector. Alternatively, follow the instructions on the Install ONTAP Antivirus Connector page.

> ⓘ For disaster recovery and MetroCluster configurations, you must set up and configure separate Vscan servers for the primary/local and secondary/partner ONTAP clusters.

Antivirus software requirements

- For information about antivirus software requirements, see the vendor documentation.
- For information about the vendors, software, and versions supported by Vscan, see the Vscan partner solutions page.

ONTAP Antivirus Connector requirements

- You can download the ONTAP Antivirus Connector from the **Software Download** page on the NetApp Support Site. NetApp Downloads: Software
- For information about the Windows versions supported by the ONTAP Antivirus Connector and interoperability requirements, see Vscan partner solutions.

> You can install different versions of Windows servers for different Vscan servers in a cluster.

- .NET 3.0 or later must be installed on the Windows server.
- SMB 2.0 must be enabled on the Windows server.

Install ONTAP Vscan Antivirus Connectors

Install the ONTAP Antivirus Connector on the Vscan server to enable communication between the system running ONTAP and the Vscan server. When the ONTAP Antivirus Connector is installed, the antivirus software is able to communicate with one or more storage virtual machines (SVMs).

About this task

- See the Vscan partner solutions page for information about the supported protocols, antivirus vendor software versions, ONTAP versions, interoperability requirements and Windows servers.
- .NET 4.5.1 or later must be installed.
- The ONTAP Antivirus Connector can run on a virtual machine. However, for best performance, NetApp recommends using a dedicated physical machine for antivirus scanning.
- SMB 2.0 must be enabled on the Windows server on which you are installing and running the ONTAP Antivirus Connector.

Before you begin

- Download the ONTAP Antivirus Connector setup file from the Support Site and save it to a directory on your hard drive.
- Verify that you meet the requirements to install the ONTAP Antivirus Connector.
- Verify that you have administrator privileges to install the Antivirus Connector.

Steps

1. Start the Antivirus Connector installation wizard by running the appropriate setup file.
2. Select *Next*. The Destination Folder dialog box opens.
3. Select *Next* to install the Antivirus Connector to the folder that is listed or select *Change* to install to a different folder.
4. The ONTAP AV Connector Windows Service Credentials dialog box opens.
5. Enter your Windows service credentials or select **Add** to select a user. For an ONTAP system, this user must be a valid domain user and must exist in the scanner pool configuration for the SVM.
6. Select **Next**. The Ready to Install the Program dialog box opens.
7. Select **Install** to begin the installation or select **Back** if you want to make any changes to the settings. A status box opens and charts the progress of the installation, followed by the InstallShield Wizard Completed dialog box.

8. Select the Configure ONTAP LIFs check box if you want to continue with the configuration of ONTAP management or data LIFs.
You must configure at least one ONTAP management or data LIF before this Vscan server can be used.
9. Select the Show the **Windows Installer log** check box if you want to view the installation logs.
10. Select **Finish** to end the installation and to close the InstallShield wizard.
The **Configure ONTAP LIFs** icon is saved on the desktop to configure the ONTAP LIFs.
11. Add an SVM to the Antivirus Connector.
You can add an SVM to the Antivirus Connector by adding either an ONTAP management LIF, which is polled to retrieve the list of data LIFs, or by directly configuring the data LIF or LIFs.
You must also provide the poll information and the ONTAP admin account credentials if the ONTAP management LIF is configured.
   ◦ Verify that the management LIF or the IP address of the SVM is enabled for `management-https`. This is not required when you are only configuring data LIFs.
   ◦ Verify that you have created a user account for the HTTP application and assigned a role which has (at least read-only) access to the `/api/network/ip/interfaces` REST API.
   ◦ Learn more about `security login role create` and `security login create` in the ONTAP command reference.

> You can also use the domain user as an account by adding an authentication tunnel SVM for an administrative SVM. Learn more about `security login domain-tunnel create` in the ONTAP command reference.

Steps

a. Right-click on the **Configure ONTAP LIFs** icon, which was saved on your desktop when you completed the Antivirus Connector installation, and then select **Run as Administrator**.
b. In the Configure ONTAP LIFs dialog box, select the preferred configuration type, then perform the following actions:

To create this type of LIF…	Perform these steps…
Data LIF	a. Set "role" to "data" b. Set "data protocol" to "cifs" c. Set "firewall policy" to "data" d. Set "service policy" to "default-data-files"
Management LIF	a. Set "role* to "data" b. Set "data protocol" to "none" c. Set "firewall policy" to "mgmt" d. Set "service policy" to "default-management"

Read more about creating a LIF.

After you create a LIF, enter the data or management LIF or IP address of the SVM that you want to add. You can also enter the cluster management LIF. If you specify the cluster management LIF, all SVMs within that cluster that are serving SMB can use the Vscan server.

When Kerberos authentication is required for Vscan servers, each SVM data LIF must have a unique DNS name, and you must register that name as a server principal name (SPN) with the Windows Active Directory. When a unique DNS name is not available for each data LIF or registered as an SPN, the Vscan server uses the NT LAN Manager mechanism for authentication. If you add or modify the DNS names and SPNs after the Vscan server is connected, you must restart the Antivirus Connector service on the Vscan server to apply the changes.

c. To configure a management LIF, enter the poll duration in seconds. The poll duration is the frequency at which the Antivirus Connector checks for changes to the SVMs or the cluster's LIF configuration. The default poll interval is 60 seconds.

d. Enter the ONTAP admin account name and password to configure a management LIF.

e. Click **Test** to check the connectivity and verify the authentication. Authentication is verified only for a management LIF configuration.

f. Click **Update** to add the LIF to the list of LIFs to poll or to connect to.

g. Click **Save** to save the connection to the registry.

h. Click **Export** if you want to export the list of connections to a registry import or registry export file. This is useful if multiple Vscan servers use the same set of management or data LIFs.

See the Configure the ONTAP Antivirus Connector page for configuration options.

Configure ONTAP Vscan Antivirus Connectors

Configure the ONTAP Antivirus Connector to specify one or more storage virtual machines (SVMs) that you want to connect to by either entering the ONTAP management LIF, poll information, and the ONTAP admin account credentials, or just the data LIF. You can also modify the details of an SVM connection or remove an SVM connection. By default, the ONTAP Antivirus Connector uses REST APIs to retrieve the list of data LIFs if the ONTAP management LIF is configured.

Modify the details of an SVM connection

You can update the details of a storage virtual machine (SVM) connection, which has been added to the Antivirus Connector, by modifying the ONTAP management LIF and the poll information. You cannot update data LIFs after they have been added. To update data LIFs you must first remove them and then add them again with the new LIF or IP address.

Before you begin

Verify that you have created a user account for the HTTP application and assigned a role which has (at least read-only) access to the `/api/network/ip/interfaces` REST API.

Learn more about `security login role create` and `security login create` in the ONTAP command reference.

You can also use the domain user as an account by adding an authentication tunnel SVM for an administrative SVM.
Learn more about `security login domain-tunnel create` in the ONTAP command reference.

Steps

1. Right-click the **Configure ONTAP LIFs** icon, which was saved on your desktop when you completed the Antivirus Connector installation, and then select **Run as Administrator**. The Configure ONTAP LIFs dialog box opens.
2. Select the SVM IP address, and then click **Update**.
3. Update the information, as required.
4. Click **Save** to update the connection details in the registry.
5. Click **Export** if you want to export the list of connections to a registry import or a registry export file. This is useful if multiple Vscan servers use the same set of management or data LIFs.

Remove an SVM connection from the Antivirus Connector

If you no longer require an SVM connection, you can remove it.

Steps

1. Right-click the **Configure ONTAP LIFs** icon, which was saved on your desktop when you completed the Antivirus Connector installation, and then select **Run as Administrator**. The Configure ONTAP LIFs dialog box opens.
2. Select one or more SVM IP addresses, and then click **Remove**.
3. Click **Save** to update the connection details in the registry.
4. Click **Export** if you want to export the list of connections to a registry import or registry export file. This is useful if multiple Vscan servers use the same set of management or data LIFs.

Troubleshoot

Before you begin

When you are creating registry values in this procedure, use the right-side pane.

You can enable or disable Antivirus Connector logs for diagnostic purposes. By default, these logs are disabled. For enhanced performance, you should keep the Antivirus Connector logs disabled and only enable them for critical events.

Steps

1. Select **Start**, type "regedit" into the search box, and then select `regedit.exe` in the Programs list.
2. In **Registry Editor**, locate the following subkey for the ONTAP Antivirus Connector: `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Data ONTAP\Clustered Data ONTAP Antivirus Connector\v1.0`
3. Create registry values by providing the type, name, and values shown in the following table:

Type	Name	Values
String	Tracepath	c:\avshim.log

   This registry value could be any other valid path.

4. Create another registry value by providing the type, name, values, and logging information shown in the following table:

Type	Name	Critical logging	Intermediate logging	Verbose logging
DWORD	Tracelevel	1	2 or 3	4

This enables Antivirus Connector logs that are saved at the path value provided in the TracePath in Step 3.

5. Disable Antivirus Connector logs by deleting the registry values you created in Steps 3 and 4.
6. Create another registry value of type "MULTI_SZ" with the name "LogRotation" (without quotes). In "LogRotation",
provide "logFileSize:1" as an entry for rotation size (where 1 represents 1MB) and in the next line, provide "logFileCount:5" as an
entry for rotation limit (5 is the limit).

> These values are optional. If they are not provided, default values of 20MB and 10 files are used for the rotation size and rotation limit respectively. Provided integer values do not provide decimal or fraction values. If you provide values higher than the default values, the default values are used instead.

7. To disable the user-configured log rotation, delete the registry values you created in Step 6.

Customizable Banner

A custom banner allows you to place a legally binding statement and a system access disclaimer on the *Configure ONTAP LIF API* window.

Step

1. Modify the default banner by updating the contents in the `banner.txt` file in the install directory and then saving the changes.
You must reopen the Configure ONTAP LIF API window to see the changes reflected in the banner.

Enable Extended Ordinance (EO) mode

You can enable and disable Extended Ordinance (EO) mode for secure operation.

Steps

1. Select **Start**, type "regedit" in the search box, and then select `regedit.exe` in the Programs list.
2. In **Registry Editor**, locate the following subkey for ONTAP Antivirus Connector:
`HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Data ONTAP\Clustered Data ONTAP Antivirus Connector\v1.0`
3. In the right-side pane, create a new registry value of type "DWORD" with the name "EO_Mode" (without quotes) and value "1" (without quotes) to enable EO Mode or value "0" (without quotes) to disable EO Mode.

> By default, if the `EO_Mode` registry entry is absent, EO mode is disabled. When you enable EO mode, you must configure both the external syslog server and mutual certificate authentication.

Configure the external syslog server

Before you begin

Take note that when you are creating registry values in this procedure, use the right-side pane.

Steps

1. Select **Start**, type "regedit" in the search box, and then select `regedit.exe` in the Programs list.
2. In **Registry Editor**, create the following subkey for ONTAP Antivirus Connector for syslog configuration: `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Data ONTAP\Clustered Data ONTAP Antivirus Connector\v1.0\syslog`
3. Create a registry value by providing the type, name, and value as shown in the following table:

Type	Name	Value
DWORD	syslog_enabled	1 or 0

Note that a "1" value enables the syslog and a "0" value disables it.

4. Create another registry value by providing the information as shown in the following table:

Type	Name
REG_SZ	Syslog_host

Provide the syslog host IP address or domain name for the value field.

5. Create another registry value by providing the information as shown in the following table:

Type	Name
REG_SZ	Syslog_port

Provide the port number on which the syslog server is running in the value field.

6. Create another registry value by providing the information as shown in the following table:

Type	Name
REG_SZ	Syslog_protocol

Enter the protocol that is in use on the syslog server, either "tcp" or "udp", in the value field.

7. Create another registry value by providing the information as shown in the following table:

Type	Name	LOG_CRIT	LOG_NOTICE	LOG_INFO	LOG_DEBUG
DWORD	Syslog_level	2	5	6	7

8. Create another registry value by providing the information as shown in the following table:

Type	Name	Value

DWORD	syslog_tls	1 or 0

Note that a "1" value enables syslog with Transport Layer Security (TLS) and a "0" value disables syslog with TLS.

Ensure a configured external syslog server runs smoothly

- If the key is absent or has a null value:
  - The protocol defaults to "tcp".
  - The port defaults to "514" for plain "tcp/udp" and defaults to "6514" for TLS.
  - The syslog level defaults to 5 (LOG_NOTICE).
- You can confirm that syslog is enabled by verifying that the `syslog_enabled` value is "1". When the `syslog_enabled` value is "1", you should be able to log in to the configured remote server whether or not EO mode is enabled.
- If EO mode is set to "1" and you change the `syslog_enabled` value from "1" to "0", the following applies:
  - You cannot start the service if syslog is not enabled in EO mode.
  - If the system is running in a steady state, a warning appears that says syslog cannot be disabled in EO mode and syslog is forcefully set to "1", which you can see in the registry. If this occurs, you should disable EO mode first and then disable syslog.
- If the syslog server is unable to run successfully when EO mode and syslog are enabled, the service stops running. This might occur for one of the following reasons:
  - An invalid or no syslog_host is configured.
  - An invalid protocol apart from UDP or TCP is configured.
  - A port number is invalid.
- For a TCP or TLS over TCP configuration, if the server is not listening on the IP port, the connection fails and the service shuts down.

Configure X.509 mutual certificate authentication

X.509 certificate based mutual authentication is possible for the Secure Sockets Layer (SSL) communication between the Antivirus Connector and ONTAP in the management path. If EO mode is enabled and the certificate is not found, the AV Connector terminates. Perform the following procedure on the Antivirus Connector:

Steps

1. The Antivirus Connector searches for the Antivirus Connector client certificate and the certificate authority (CA) certificate for the NetApp server in the directory path from where the Antivirus Connector runs the install directory. Copy the certificates into this fixed directory path.
2. Embed the client certificate and its private key in the PKCS12 format and name it "AV_client.P12".
3. Ensure the CA certificate (along with any intermediate signing authority up to the root CA) used to sign the certificate for the NetApp server is in the Privacy Enhanced Mail (PEM) format and named "Ontap_CA.pem". Place it in the Antivirus Connector install directory. On the NetApp ONTAP system, install the CA certificate (along with any intermediate signing authority up to the root CA) used to sign the client certificate for the Antivirus Connector at "ONTAP" as a "client-ca" type certificate.

Configure scanner pools

Learn about configuring ONTAP Vscan scanner pools

A scanner pool defines the Vscan servers and privileged users that can connect to SVMs. A scanner policy determines whether a scanner pool is active.

> If you use an export policy on an SMB server, you must add each Vscan server to the export policy.

Create an ONTAP Vscan scanner pool on a single cluster

A scanner pool defines the Vscan servers and privileged users that can connect to SVMs.

Before you begin

- SVMs and Vscan servers must be in the same domain or in trusted domains.
- Configure an ONTAP Antivirus Connector with the cluster management LIF.
- The list of privileged users must include the domain and user name the Vscan server uses to connect to the SVM.
- Once the scanner pool is configured, check the connection status to the servers.

Steps

1. Create a scanner pool:

   ```
   vserver vscan scanner-pool create -vserver cluster_admin_SVM -scanner-pool
   scanner_pool -hostnames Vscan_server_hostnames -privileged-users
   privileged_users
   ```

   - Specify a cluster admin SVM.
   - Specify an IP address or FQDN for each Vscan server host name.
   - Specify the domain and user name for each privileged user.

   Learn more about `vserver vscan scanner-pool create` in the ONTAP command reference.

2. Verify that the scanner pool was created:

   ```
   vserver vscan scanner-pool show -vserver cluster_admin_SVM -scanner-pool
   scanner_pool
   ```

   The following command displays the details for the `SP` scanner pool:

```
cluster1::> vserver vscan scanner-pool show -vserver cluster_admin_SVM
-scanner-pool SP

                                    Vserver: cluster_admin_SVM
                               Scanner Pool: SP
                             Applied Policy: idle
                             Current Status: off
         Cluster on Which Policy Is Applied: -
                  Scanner Pool Config Owner: cluster
       List of IPs of Allowed Vscan Servers: 1.1.1.1, 10.72.204.27
List of Host Names of Allowed Vscan Servers: 1.1.1.1, vmwin204-
27.fsct.nb
                   List of Privileged Users: cifs\u1, cifs\u2
```

You can also use the `vserver vscan scanner-pool show` command to view all the scanner pools on the cluster. Learn more about `vserver vscan scanner-pool show` in the [ONTAP command reference](https://docs.netapp.com/us-en/ontap-cli/vserver-vscan-scanner-pool-show.html).

Create ONTAP Vscan scanner pools in MetroCluster configurations

You must create primary and secondary scanner pools on each cluster in a MetroCluster configuration, corresponding to the primary and secondary SVMs on the cluster.

Before you begin

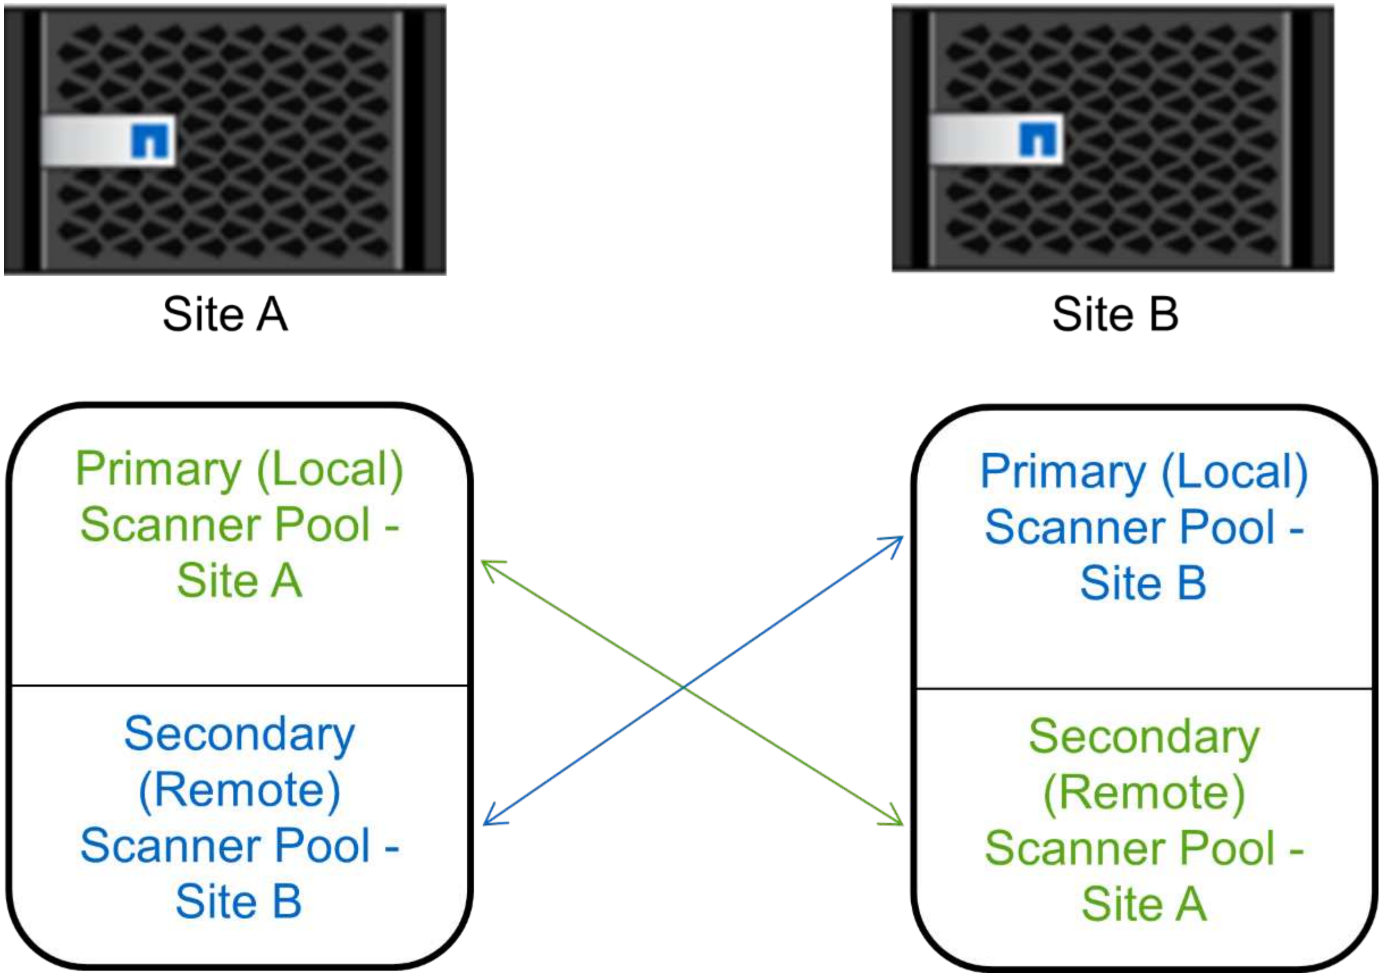
- SVMs and Vscan servers must be in the same domain or in trusted domains.
- For scanner pools defined for an individual SVM, you must have configured ONTAP Antivirus Connector with the SVM management LIF or SVM data LIF.
- For scanner pools defined for all the SVMs in a cluster, you must have configured ONTAP Antivirus Connector with the cluster management LIF.
- The list of privileged users must include the domain user account the Vscan server uses to connect to the SVM.
- Once the scanner pool is configured, check the connection status to the servers.

About this task

MetroCluster configurations protect data by implementing two physically separate mirrored clusters. Each cluster synchronously replicates the data and SVM configuration of the other. A primary SVM on the local cluster serves data when the cluster is online. A secondary SVM on the local cluster serves data when the remote cluster is offline.

This means that you must create primary and secondary scanner pools on each cluster in a MetroCluster configuration, The secondary pool becomes active when the cluster begins serving data from the secondary SVM. For Disaster Recovery (DR) the configuration is similar to MetroCluster.

This figure shows a typical MetroCluster/DR configuration.



Steps

1. Create a scanner pool:

   `vserver vscan scanner-pool create -vserver` *`data_SVM|cluster_admin_SVM`* `-scanner -pool` *`scanner_pool`* `-hostnames` *`Vscan_server_hostnames`* `-privileged-users` *`privileged_users`*

   - Specify a data SVM for a pool defined for an individual SVM, and specify a cluster admin SVM for a pool defined for all the SVMs in a cluster.
   - Specify an IP address or FQDN for each Vscan server host name.
   - Specify the domain and user name for each privileged user.

   > ⓘ You must create all scanner pools from the cluster containing the primary SVM.

   Learn more about `vserver vscan scanner-pool create` in the ONTAP command reference.

   The following commands create primary and secondary scanner pools on each cluster in a MetroCluster configuration:

```
cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool1_for_site1 -hostnames scan1 -privileged-users cifs
\u1,cifs\u2

cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool1_for_site2 -hostnames scan1 -privileged-users cifs
\u1,cifs\u2

cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool2_for_site1 -hostnames scan2 -privileged-users cifs
\u1,cifs\u2

cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool2_for_site2 -hostnames scan2 -privileged-users cifs
\u1,cifs\u2
```

2. Verify that the scanner pools were created:

   `vserver vscan scanner-pool show -vserver` *`data_SVM|cluster_admin_SVM`* `-scanner -pool` *`scanner_pool`*

   The following command displays the details for the scanner pool `pool1`:

```
cluster1::> vserver vscan scanner-pool show -vserver cifssvm1 -scanner
-pool pool1_for_site1

                                    Vserver: cifssvm1
                               Scanner Pool: pool1_for_site1
                             Applied Policy: idle
                             Current Status: off
         Cluster on Which Policy Is Applied: -
                  Scanner Pool Config Owner: vserver
       List of IPs of Allowed Vscan Servers:
List of Host Names of Allowed Vscan Servers: scan1
                   List of Privileged Users: cifs\u1,cifs\u2
```

   You can also use the `vserver vscan scanner-pool show` command to view all of the scanner pools on an SVM. Learn more about `vserver vscan scanner-pool show` in the ONTAP command reference.

Apply a scanner policy on a single cluster with ONTAP Vscan

A scanner policy determines whether a scanner pool is active. You must activate a scanner pool before the Vscan servers that it defines can connect to an SVM.

About this task

- You can apply only one scanner policy to a scanner pool.
- If you created a scanner pool for all the SVMs in a cluster, you must apply a scanner policy on each SVM individually.

Steps

1. Apply a scanner policy:

   `vserver vscan scanner-pool apply-policy -vserver data_SVM -scanner-pool scanner_pool -scanner-policy primary|secondary|idle -cluster cluster_to_apply_policy_on`

   A scanner policy can have one of the following values:

   - `Primary` specifies that the scanner pool is active.
   - `Secondary` specifies that the scanner pool is active only if none of the Vscan servers in the primary scanner pool are connected.
   - `Idle` specifies that the scanner pool is inactive.

     The following example shows that the scanner pool named `SP` on the `vs1` SVM is active:

     ```
     cluster1::> vserver vscan scanner-pool apply-policy -vserver vs1
     -scanner-pool SP  -scanner-policy primary
     ```

2. Verify that the scanner pool is active:

   `vserver vscan scanner-pool show -vserver data_SVM|cluster_admin_SVM -scanner -pool scanner_pool`

   Learn more about the commands described in this procedure in the ONTAP command reference.

   The following command displays the details for the `SP` scanner pool:

   ```
   cluster1::> vserver vscan scanner-pool show -vserver vs1 -scanner-pool
   SP

                                       Vserver: vs1
                                  Scanner Pool: SP
                                Applied Policy: primary
                                Current Status: on
            Cluster on Which Policy Is Applied: cluster1
                     Scanner Pool Config Owner: vserver
          List of IPs of Allowed Vscan Servers: 1.1.1.1, 10.72.204.27
   List of Host Names of Allowed Vscan Servers: 1.1.1.1, vmwin204-
   27.fsct.nb
                      List of Privileged Users: cifs\u1, cifs\u2
   ```

You can use the `vserver vscan scanner-pool show-active` command to view the active scanner pools on an SVM. Learn more about `vserver vscan scanner-pool show-active` in the ONTAP command reference.

Apply scanner policies in MetroCluster ONTAP Vscan configurations

A scanner policy determines whether a scanner pool is active. You must apply a scanner policy to the primary and secondary scanner pools on each cluster in a MetroCluster configuration.

About this task

- You can apply only one scanner policy to a scanner pool.
- If you created a scanner pool for all the SVMs in a cluster, you must apply a scanner policy on each SVM individually.
- For disaster recovery and MetroCluster configurations, you must apply a scanner policy to every scanner pool in the local cluster and remote cluster.
- In the policy that you create for the local cluster, you must specify the local cluster in the `cluster` parameter. In the policy that you create for the remote cluster, you must specify the remote cluster in the `cluster` parameter. The remote cluster can then take over virus scanning operations in case of a disaster.

Steps

1. Apply a scanner policy:

   ```
   vserver vscan scanner-pool apply-policy -vserver data_SVM -scanner-pool
   scanner_pool -scanner-policy primary|secondary|idle -cluster
   cluster_to_apply_policy_on
   ```

   Learn more about `vserver vscan scanner-pool apply-policy` in the ONTAP command reference.

   A scanner policy can have one of the following values:

   - `Primary` specifies that the scanner pool is active.
   - `Secondary` specifies that the scanner pool is active only if none of the Vscan servers in the primary scanner pool are connected.
   - `Idle` specifies that the scanner pool is inactive.

     > You must apply all scanner policies from the cluster containing the primary SVM.

     The following commands apply scanner policies to the primary and secondary scanner pools on each cluster in a MetroCluster configuration:

```
cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1
-scanner-pool pool1_for_site1 -scanner-policy primary -cluster
cluster1

cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1
-scanner-pool pool2_for_site1 -scanner-policy secondary -cluster
cluster1

cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1
-scanner-pool pool2_for_site2 -scanner-policy primary -cluster
cluster2

cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1
-scanner-pool pool1_for_site2 -scanner-policy secondary -cluster
cluster2
```

2. Verify that the scanner pool is active:

   `vserver vscan scanner-pool show -vserver data_SVM|cluster_admin_SVM -scanner -pool scanner_pool`

   Learn more about `vserver vscan scanner-pool show` in the ONTAP command reference.

   The following command displays the details for the scanner pool `pool1`:

```
cluster1::> vserver vscan scanner-pool show -vserver cifssvm1 -scanner
-pool pool1_for_site1

                                    Vserver: cifssvm1
                               Scanner Pool: pool1_for_site1
                             Applied Policy: primary
                             Current Status: on
         Cluster on Which Policy Is Applied: cluster1
                  Scanner Pool Config Owner: vserver
       List of IPs of Allowed Vscan Servers:
List of Host Names of Allowed Vscan Servers: scan1
                   List of Privileged Users: cifs\u1,cifs\u2
```

   You can use the `vserver vscan scanner-pool show-active` command to view the active scanner pools on an SVM. Learn more about `vserver vscan scanner-pool show-active` in the ONTAP command reference.

ONTAP commands for managing scanner pools in Vscan

You can modify and delete scanner pools, and manage privileged users and Vscan servers for a scanner pool. You can also view summary information about the scanner pool.

If you want to…	Enter the following command…
Modify a scanner pool	`vserver vscan scanner-pool modify`
Delete a scanner pool	`vserver vscan scanner-pool delete`
Add privileged users to a scanner pool	`vserver vscan scanner-pool privileged-users add`
Delete privileged users from a scanner pool	`vserver vscan scanner-pool privileged-users remove`
Add Vscan servers to a scanner pool	`vserver vscan scanner-pool servers add`
Delete Vscan servers from a scanner pool	`vserver vscan scanner-pool servers remove`
View summary and details for a scanner pool	`vserver vscan scanner-pool show`
View privileged users for a scanner pool	`vserver vscan scanner-pool privileged-users show`
View Vscan servers for all scanner pools	`vserver vscan scanner-pool servers show`

Learn more about the commands described in this procedure in the ONTAP command reference.

Configure on-access scanning

Create ONTAP Vscan on-access policies

An on-access policy defines the scope of an on-access scan. You can create an on-access policy for an individual SVM or for all the SVMs in a cluster. If you created an on-access policy for all the SVMs in a cluster, you must enable the policy on each SVM individually.

About this task

- You can specify the maximum file size to scan, file extensions and paths to include in the scan, and file extensions and paths to exclude from the scan.
- You can set the `scan-mandatory` option to off to specify that file access is allowed when no Vscan servers are available for virus scanning.
- By default, ONTAP creates an on-access policy named "default_CIFS" and enables it for all the SVMs in a cluster.

* Any file that qualifies for scan exclusion based on the `paths-to-exclude`, `file-ext-to-exclude`, or `max-file-size` parameters is not considered for scanning, even if the `scan-mandatory` option is set to on. (Check this troubleshooting section for connectivity issues related to the `scan-mandatory` option.)
* By default, only read-write volumes are scanned. You can specify filters that enable scanning of read-only volumes or that restrict scanning to files opened with execute access.
* Virus scanning is not performed on an SMB share for which the continuously-available parameter is set to Yes.
* See the Antivirus architecture section for details about the *Vscan file-operations profile*.
* You can create a maximum of ten (10) on-access policies per SVM. However, you can enable only one on-access policy at a time.
  ◦ You can exclude a maximum of one hundred (100) paths and file extensions from virus scanning in an on-access policy.
* Some file exclusion recommendations:
  ◦ Consider excluding large files (file size can be specified) from virus scanning because they can result in a slow response or scan request timeouts for CIFS users. The default file size for exclusion is 2GB.
  ◦ Consider excluding file extensions such as `.vhd` and `.tmp` because files with these extensions might not be appropriate for scanning.
  ◦ Consider excluding file paths such as the quarantine directory or paths in which only virtual hard drives or databases are stored.
  ◦ Verify that all exclusions are specified in the same policy, because only one policy can be enabled at a time. NetApp highly recommends having the same set of exclusions specified in the antivirus engine.
* An on-access policy is required for an on-demand scan. To avoid on-access scanning for, you should set `-scan-files-with-no-ext` to false and `-file-ext-to-exclude` to * to exclude all extensions.

Steps

1. Create an on-access policy:

   `vserver vscan on-access-policy create -vserver` *`data_SVM|cluster_admin_SVM`* `-policy-name` *`policy_name`* `-protocol CIFS -max-file-size` *`max_size_of_files_to_scan`* `–filters [scan-ro-volume,][scan-execute-access] -file-ext-to-include` *`extensions_of_files_to_include`* `-file-ext-to-exclude` *`extensions_of_files_to_exclude`* `-scan-files-with-no-ext true|false -paths-to -exclude` *`paths_of_files_to_exclude`* `-scan-mandatory on|off`

   ◦ Specify a data SVM for a policy defined for an individual SVM, a cluster admin SVM for a policy defined for all the SVMs in a cluster.

   ◦ The `-file-ext-to-exclude` setting overrides the `-file-ext-to-include` setting.

   ◦ Set `-scan-files-with-no-ext` to true to scan files without extensions.
   The following command creates an on-access policy named `Policy1` on the `vs1` SVM:

```
cluster1::> vserver vscan on-access-policy create -vserver vs1 -policy
-name Policy1 -protocol CIFS -filters scan-ro-volume -max-file-size 3GB
-file-ext-to-include "mp*","tx*" -file-ext-to-exclude "mp3","txt" -scan
-files-with-no-ext false -paths-to-exclude "\vol\a b\","\vol\a,b\"
```

2. Verify that the on-access policy has been created: `vserver vscan on-access-policy show -instance data_SVM|cluster_admin_SVM -policy-name name`

   Learn more about `vserver vscan on-access-policy` in the ONTAP command reference.

   The following command displays the details for the `Policy1` policy:

```
cluster1::> vserver vscan on-access-policy show -instance vs1 -policy
-name Policy1

                           Vserver: vs1
                            Policy: Policy1
                     Policy Status: off
               Policy Config Owner: vserver
              File-Access Protocol: CIFS
                           Filters: scan-ro-volume
                    Mandatory Scan: on
Max File Size Allowed for Scanning: 3GB
            File Paths Not to Scan: \vol\a b\, \vol\a,b\
       File Extensions Not to Scan: mp3, txt
           File Extensions to Scan: mp*, tx*
      Scan Files with No Extension: false
```

Enable ONTAP Vscan on-access policies

An on-access policy defines the scope of an on-access scan. You must enable an on-access policy on an SVM before its files can be scanned.

If you created an on-access policy for all the SVMs in a cluster, you must enable the policy on each SVM individually. You can enable only one on-access policy on an SVM at a time.

Steps

1. Enable an on-access policy:

   `vserver vscan on-access-policy enable -vserver data_SVM -policy-name policy_name`

   The following command enables an on-access policy named `Policy1` on the `vs1` SVM:

```
cluster1::> vserver vscan on-access-policy enable -vserver vs1 -policy
-name Policy1
```

2. Verify that the on-access policy is enabled:

   `vserver vscan on-access-policy show -instance data_SVM -policy-name policy_name`

Learn more about `vserver vscan on-access-policy show` in the ONTAP command reference.

The following command displays the details for the `Policy1` on-access policy:

```
cluster1::> vserver vscan on-access-policy show -instance vs1 -policy
-name Policy1

                           Vserver: vs1
                            Policy: Policy1
                     Policy Status: on
               Policy Config Owner: vserver
              File-Access Protocol: CIFS
                           Filters: scan-ro-volume
                    Mandatory Scan: on
Max File Size Allowed for Scanning: 3GB
            File Paths Not to Scan: \vol\a b\, \vol\a,b\
       File Extensions Not to Scan: mp3, txt
           File Extensions to Scan: mp*, tx*
      Scan Files with No Extension: false
```

Modify the ONTAP Vscan file-operations profile for SMB shares

The *Vscan file-operations profile* for an SMB share defines the operations on the share that can trigger scanning. By default, the parameter is set to `standard`. You can adjust the parameter as necessary when you create or modify an SMB share.

See the Antivirus architecture section for details about the *Vscan file-operations profile*.

Virus scanning is not performed on an SMB share that has the `continuously-available` parameter set to `Yes`.

Step

1. Modify the value of the Vscan file-operations profile for an SMB share:

   `vserver cifs share modify -vserver data_SVM -share-name share -path share_path -vscan-fileop-profile no-scan|standard|strict|writes-only`

   Learn more about `vserver cifs share modify` in the ONTAP command reference.

   The following command changes the Vscan file operations profile for an SMB share to `strict`:

```
cluster1::> vserver cifs share modify -vserver vs1 -share-name
SALES_SHARE -path /sales -vscan-fileop-profile strict
```

ONTAP Vscan commands for managing on-access policies

You can modify, disable, or delete an on-access policy. You can view a summary and details for the policy.

If you want to…	Enter the following command…
Create an on-access policy	`vserver vscan on-access-policy create`
Modify an on-access policy	`vserver vscan on-access-policy modify`
Enable an on-access policy	`vserver vscan on-access-policy enable`
Disable an on-access policy	`vserver vscan on-access-policy disable`
Delete an on-access policy	`vserver vscan on-access-policy delete`
View summary and details for an on-access policy	`vserver vscan on-access-policy show`
Add to the list of paths to exclude	`vserver vscan on-access-policy paths-to-exclude add`
Delete from the list of paths to exclude	`vserver vscan on-access-policy paths-to-exclude remove`
View the list of paths to exclude	`vserver vscan on-access-policy paths-to-exclude show`
Add to the list of file extensions to exclude	`vserver vscan on-access-policy file-ext-to-exclude add`
Delete from the list of file extensions to exclude	`vserver vscan on-access-policy file-ext-to-exclude remove`
View the list of file extensions to exclude	`vserver vscan on-access-policy file-ext-to-exclude show`
Add to the list of file extensions to include	`vserver vscan on-access-policy file-ext-to-include add`
Delete from the list of file extensions to include	`vserver vscan on-access-policy file-ext-to-include remove`
View the list of file extensions to include	`vserver vscan on-access-policy file-ext-to-include show`

Learn more about the commands described in this procedure in the ONTAP command reference.

Configure on-demand scanning

Learn about configuring ONTAP Vscan on-demand scanning

You can use on-demand scanning to check files for viruses immediately or on a schedule.

You might want to run scans only in off-peak hours, for example, or you might want to scan very large files that were excluded from an on-access scan. You can use a cron schedule to specify when the task runs.

> To create an on-demand task, there must be at least one on-access policy enabled. It can be the default policy or a user created on-access policy.

About this topic

- You can assign a schedule when you create a task.
- Only one task can be scheduled at a time on an SVM.
- On-demand scanning does not support scanning of symbolic links or stream files.

> On-demand scanning does not support scanning of symbolic links or stream files.

> To create an on-demand task, there must be at least one on-access policy enabled. It can be the default policy or a user created on-access policy.

Create on-demand tasks with ONTAP Vscan

An on-demand task defines the scope of the on-demand virus scan. You can specify the maximum size of the files to be scanned, the extensions and paths of the files to be included in the scan, and the extensions and paths of the files to be excluded from the scan. Files in subdirectories are scanned by default.

About this task

- A maximum of ten (10) on-demand tasks can exist for each SVM, but only one can be active.
- An on-demand task creates a report, which has information regarding the statistics related to the scans. This report is accessible with a command or by downloading the report file created by the task at the location defined.

Before you begin

- You must have created an on-access policy. The policy can be a default or user-created one. Without the on-access policy, you cannot enable the scan.

Steps

1. Create an on-demand task:

```
vserver vscan on-demand-task create -vserver data_SVM -task-name task_name
-scan-paths paths_of_files_to_scan -report-directory report_directory_path
-report-expiry-time expiration_time_for_report -schedule cron_schedule -max
-file-size max_size_of_files_to_scan -paths-to-exclude paths -file-ext-to
-exclude file_extensions -file-ext-to-include file_extensions -scan-files-with
```

`-no-ext true|false -directory-recursion true|false`

  - The `-file-ext-to-exclude` setting overrides the `-file-ext-to-include` setting.
  - Set `-scan-files-with-no-ext` to true to scan files without extensions.

  Learn more about `vserver vscan on-demand-task create` in the ONTAP command reference.

The following command creates an on-demand task named `Task1` on the \`vs1\`SVM:

```
cluster1::> vserver vscan on-demand-task create -vserver vs1 -task-name
Task1 -scan-paths "/vol1/","/vol2/cifs/" -report-directory "/report"
-schedule daily -max-file-size 5GB -paths-to-exclude "/vol1/cold-files/"
-file-ext-to-include "vmdk?","mp*" -file-ext-to-exclude "mp3","mp4"
-scan-files-with-no-ext false
[Job 126]: Vscan On-Demand job is queued. Use the "job show -id 126"
command to view the status.
```

> You can use the `job show` command to view the status of the job. You can use the `job pause` and `job resume` commands to pause and restart the job, or the `job stop` command to end the job. Learn more about `job` in the ONTAP command reference.

2. Verify that the on-demand task has been created:

   `vserver vscan on-demand-task show -instance data_SVM -task-name task_name`

   Learn more about `vserver vscan on-demand-task show` in the ONTAP command reference.

   The following command displays the details for the `Task1` task:

```
cluster1::> vserver vscan on-demand-task show -instance vs1 -task-name
Task1

                           Vserver: vs1
                         Task Name: Task1
                List of Scan Paths: /vol1/, /vol2/cifs/
             Report Directory Path: /report
                      Job Schedule: daily
Max File Size Allowed for Scanning: 5GB
            File Paths Not to Scan: /vol1/cold-files/
       File Extensions Not to Scan: mp3, mp4
           File Extensions to Scan: vmdk?, mp*
      Scan Files with No Extension: false
           Request Service Timeout: 5m
                    Cross Junction: true
               Directory Recursion: true
                     Scan Priority: low
                  Report Log Level: info
        Expiration Time for Report: -
```

After you finish

You must enable scanning on the SVM before the task is scheduled to run.

Schedule on-demand tasks with ONTAP Vscan

You can create a task without assigning a schedule and use the `vserver vscan on-demand-task schedule` command to assign a schedule; or add a schedule while creating the task.

About this task

The schedule assigned with the `vserver vscan on-demand-task schedule` command overrides a schedule already assigned with the `vserver vscan on-demand-task create` command.

Steps

1. Schedule an on-demand task:

   `vserver vscan on-demand-task schedule -vserver` *`data_SVM`* `-task-name` *`task_name`* `-schedule cron_schedule`

   The following command schedules an on-access task named `Task2` on the `vs2` SVM:

```
cluster1::> vserver vscan on-demand-task schedule -vserver vs2 -task
-name Task2 -schedule daily
[Job 142]: Vscan On-Demand job is queued. Use the "job show -id 142"
command to view the status.
```

Learn more about `vserver vscan on-demand-task schedule` in the ONTAP command reference.

> ⓘ To view the status of the job, use the `job show` command. The `job pause` and `job resume` commands, respectively pause and restart the job; the `job stop` command terminates the job. Learn more about `job` in the ONTAP command reference.

2. Verify that the on-demand task has been scheduled:

   `vserver vscan on-demand-task show -instance` *`data_SVM`* `-task-name` *`task_name`*

   Learn more about `vserver vscan on-demand-task show` in the ONTAP command reference.

   The following command displays the details for the `Task 2` task:

```
cluster1::> vserver vscan on-demand-task show -instance vs2 -task-name
Task2

                           Vserver: vs2
                         Task Name: Task2
                List of Scan Paths: /vol1/, /vol2/cifs/
             Report Directory Path: /report
                      Job Schedule: daily
Max File Size Allowed for Scanning: 5GB
            File Paths Not to Scan: /vol1/cold-files/
       File Extensions Not to Scan: mp3, mp4
           File Extensions to Scan: vmdk, mp*
      Scan Files with No Extension: false
           Request Service Timeout: 5m
                    Cross Junction: true
               Directory Recursion: true
                     Scan Priority: low
                  Report Log Level: info
```

After you finish

You must enable scanning on the SVM before the task is scheduled to run.

Run ONTAP Vscan on-demand tasks immediately

You can run an on-demand task immediately, whether or not you have assigned a schedule.

Before you begin

You must have enabled scanning on the SVM.

Step

1. Run an on-demand task immediately:

`vserver vscan on-demand-task run -vserver data_SVM -task-name task_name`

The following command runs an on-access task named `Task1` on the `vs1` SVM:

```
cluster1::> vserver vscan on-demand-task run -vserver vs1 -task-name
Task1
[Job 161]: Vscan On-Demand job is queued. Use the "job show -id 161"
command to view the status.
```

Learn more about `vserver vscan on-demand-task run` in the ONTAP command reference.

You can use the `job show` command to view the status of the job. You can use the `job pause` and `job resume` commands to pause and restart the job, or the `job stop` command to end the job. Learn more about `job` in the ONTAP command reference.

ONTAP Vscan commands for managing on-demand tasks

You can modify, delete, or unschedule an on-demand task. You can view a summary and details for the task, and manage reports for the task.

If you want to…	Enter the following command…
Create an on-demand task	`vserver vscan on-demand-task create`
Modify an on-demand task	`vserver vscan on-demand-task modify`
Delete an on-demand task	`vserver vscan on-demand-task delete`
Run an on-demand task	`vserver vscan on-demand-task run`
Schedule an on-demand task	`vserver vscan on-demand-task schedule`
Unschedule an on-demand task	`vserver vscan on-demand-task unschedule`
View summary and details for an on-demand task	`vserver vscan on-demand-task show`
View on-demand reports	`vserver vscan on-demand-task report show`
Delete on-demand reports	`vserver vscan on-demand-task report delete`

Learn more about the commands described in this procedure in the ONTAP command reference.

Best practices for configuring the off-box antivirus functionality in ONTAP Vscan

Consider the following recommendations for configuring the off-box functionality in ONTAP.

- Restrict privileged users to virus scanning operations. Normal users should be discouraged from using privileged user credentials. This restriction can be achieved by turning off login rights for privileged users on Active Directory.
- Privileged users are not required to be part of any user group that has a large number of rights in the domain, such as the administrators group or the backup operators group. Privileged users must be validated only by the storage system so that they are allowed to create Vscan server connections and access files for virus scanning.
- Use the computers running Vscan servers only for virus scanning purposes. To discourage general use, disable the Windows terminal services and other remote access provisions on these machines, and grant the right to install new software on these machines only to administrators.
- Dedicate the Vscan servers to virus scanning and do not use them for other operations, such as backups. You might decide to run the Vscan server as a virtual machine (VM). If you run the Vscan server as a VM, make sure that the resources allocated to the VM are not shared and are enough to perform virus scanning.
- Provide adequate CPU, memory, and disk capacity to the Vscan server to avoid over allocation of resources. Most Vscan servers are designed to use multiple CPU core servers and to distribute the load across the CPUs.
- NetApp recommends using a dedicated network with a private VLAN for the connection from the SVM to the Vscan server so that the scan traffic is not affected by other client network traffic. Create a separate network interface card (NIC) that is dedicated to the antivirus VLAN on the Vscan server and to the data LIF on the SVM. This step simplifies administration and troubleshooting if network issues arise. The antivirus traffic should be segregated using a private network. The antivirus server should be configured to communicate with the domain controller (DC) and ONTAP in one of the following ways:
  - The DC should communicate to the antivirus servers through the private network that is used to segregate the traffic.
  - The DC and antivirus server should communicate through a different network (not the private network mentioned previously), which is not the same as the CIFS client network.
  - To enable Kerberos authentication for antivirus communication, create a DNS entry for the private LIFs and a service principal name on the DC corresponding to the DNS entry created for the private LIF. Use this name when adding a LIF to the Antivirus Connector. The DNS should be able to return a unique name for each private LIF connected to the Antivirus Connector.

> If the LIF for Vscan traffic is configured on a different port than the LIF for client traffic, the Vscan LIF might fail over to another node if a port failure occurs. The change makes the Vscan server not reachable from the new node and the scan notifications for file operations on the node fail. Verify that the Vscan server is reachable through at least one LIF on a node so that it can process scan requests for file operations performed on that node.

- Connect the NetApp storage system and the Vscan server by using at least a 1GbE network.
- For an environment with multiple Vscan servers, connect all servers that have similar high-performing network connections. Connecting the Vscan servers improves performance by allowing load sharing.
- For remote sites and branch offices, NetApp recommends using a local Vscan server rather than a remote Vscan server because the former is a perfect candidate for high latency. If cost is a factor, use a laptop or PC for moderate virus protection. You can schedule periodic complete file system scans by sharing the

volumes or qtrees and scanning them from any system in the remote site.

- Use multiple Vscan servers to scan the data on the SVM for load-balancing and redundancy purposes. The amount of CIFS workload and resulting antivirus traffic vary per SVM. Monitor CIFS and virus-scanning latency on the storage controller. Monitor the trend of the results over time. If CIFS latency and virus-scanning latency increases due to CPU or application queues on the Vscan servers beyond trend thresholds, CIFS clients might experience long wait times. Add additional Vscan servers to distribute the load.
- Install the latest version of ONTAP Antivirus Connector.
- Keep antivirus engines and definitions up to date. Consult partners for recommendations on how often you should update.
- In a multi-tenancy environment, a scanner pool (pool of Vscan servers) can be shared with multiple SVMs provided that the Vscan servers and the SVMs are part of the same domain or trusted domain.
- The antivirus software policy for infected files should be set to "delete" or "quarantine", which is the default value set by most antivirus vendors. If the "vscan-fileop-profile" is set to "write_only", and if an infected file is found, the file remains in the share and can be opened because opening a file does not trigger a scan. The antivirus scan is triggered only after the file is closed.
- The `scan-engine timeout` value should be lesser than the `scanner-pool request-timeout` value.
  If it is set to a higher value, access to files might be delayed and might eventually time out.
  To avoid this, configure the `scan-engine timeout` to 5 seconds less than the `scanner-pool request-timeout` value. Refer to the scan engine vendor's documentation for instructions on how to change the `scan-engine timeout` settings. The `scanner-pool timeout` can be changed by using the following command in advanced mode and by providing the appropriate value for the `request-timeout` parameter:
  `vserver vscan scanner-pool modify`.
- For an environment that is sized for on-access scanning workloads and requires the use of on-demand scanning, NetApp recommends scheduling the on-demand scan job in off-peak hours to avoid additional loads on the existing antivirus infrastructure.

Learn more about best practices specific to partners at Vscan partner solutions.

Enable virus scanning on SVM ONTAP Vscan

You must enable virus scanning on an SVM before an on-access or on-demand scan can run.

Steps

1. Enable virus scanning on an SVM:

   ```
   vserver vscan enable -vserver data_SVM
   ```

   Learn more about `vserver vscan enable` in the ONTAP command reference.

   > You can use the `vserver vscan disable` command to disable virus scanning, if necessary. Learn more about `vserver vscan disable` in the ONTAP command reference.

   The following command enables virus scanning on the `vs1` SVM:

```
cluster1::> vserver vscan enable -vserver vs1
```

2. Verify that virus scanning is enabled on the SVM:

   `vserver vscan show -vserver data_SVM`

   Learn more about `vserver vscan show` in the ONTAP command reference.

   The following command displays the Vscan status of the `vs1` SVM:

```
cluster1::> vserver vscan show -vserver vs1

                           Vserver: vs1
                      Vscan Status: on
```

Reset status of ONTAP Vscan scanned files

Occasionally, you might want to reset the scan status of successfully scanned files on an SVM by using the `vserver vscan reset` command to discard the cached information for the files. You might want to use this command to restart the virus scanning processing in case of a misconfigured scan, for example. Learn more about `vserver vscan reset` in the ONTAP command reference.

About this task

After you run the `vserver vscan reset` command, all eligible files will be scanned the next time they are accessed.

> This command can affect performance adversely, depending on the number and size of the files to be rescanned.

Before you begin

Advanced privileges are required for this task.

Steps

1. Change to advanced privilege level:

   `set -privilege advanced`

   Learn more about `set -privilege advanced` in the ONTAP command reference.

2. Reset the status of scanned files:

   `vserver vscan reset -vserver data_SVM`

   The following command resets the status of scanned files on the `vs1` SVM:

```
cluster1::> vserver vscan reset -vserver vs1
```

View Vscan event log information with ONTAP

You can use the `vserver vscan show-events` command to view event log information about infected files, updates to Vscan servers, and the like. You can view event information for the cluster or for given nodes, SVMs, or Vscan servers.

Before you begin

Advanced privileges are required to view the Vscan event log.

Steps

1. Change to advanced privilege level:

   `set -privilege advanced`

   Learn more about `set` in the ONTAP command reference.

2. View Vscan event log information:

   `vserver vscan show-events`

   Learn more about `vserver vscan show-events` in the ONTAP command reference.

   The following command displays event log information for the cluster `cluster1`:

```
cluster1::*> vserver vscan show-events

Vserver     Node            Server          Event Type        Event Time
----------- --------------- --------------- -----------------
-----------------
vs1         Cluster-01      192.168.1.1     file-infected     9/5/2014
11:37:38
vs1         Cluster-01      192.168.1.1     scanner-updated   9/5/2014
11:37:08
vs1         Cluster-01      192.168.1.1     scanner-connected 9/5/2014
11:34:55
3 entries were displayed.
```

Monitor and troubleshoot connectivity issues

Potential ONTAP Vscan connectivity issues involving the scan-mandatory option

You can use the `vserver vscan connection-status show` commands to view information about Vscan server connections that you might find helpful in troubleshooting connectivity issues.

By default, the `scan-mandatory` option for on-access scanning denies file access when a Vscan server connection is not available for scanning. Although this option offers important safety features, it can lead to problems in a few situations.

- Before enabling client access, you must ensure that at least one Vscan server is connected to an SVM on each node that has a LIF. If you need to connect servers to SVMs after enabling client access, you must turn off the `scan-mandatory` option on the SVM to ensure that file access is not denied because a Vscan server connection is not available. You can turn the option back on after the server has been connected.
- If a target LIF hosts all the Vscan server connections for an SVM, the connection between the server and the SVM will be lost if the LIF is migrated. To ensure that file access is not denied because a Vscan server connection is not available, you must turn off the `scan-mandatory` option before migrating the LIF. You can turn the option back on after the LIF has been migrated.

Each SVM should have at least two Vscan servers assigned to it. It is a best practice to connect Vscan servers to the storage system over a different network from the one used for client access.

Learn more about `vserver vscan connection-status show` in the ONTAP command reference.

ONTAP commands for viewing Vscan server connection status

You can use the `vserver vscan connection-status show` commands to view summary and detailed information about Vscan server connection status.

If you want to…	Enter the following command…
View a summary of Vscan server connections	`vserver vscan connection-status show`
View details for Vscan server connections	`vserver vscan connection-status show-all`
View details for connected Vscan servers	`vserver vscan connection-status show-connected`
View details for available Vscan servers that are not connected	`vserver vscan connection-status show-not-connected`

Learn more about `vserver vscan connection-status show` in the ONTAP command reference.

Troubleshoot virus ONTAP Vscan scanning

For common virus scanning issues, there are possible causes and ways to resolve them. Virus scanning is also known as Vscan.

Issue	How to resolve it

The Vscan servers are not able to connect to the clustered ONTAP storage system.	Check whether the scanner pool configuration specifies the Vscan server IP address. Check also if the allowed privileged users in the scanner pool list are active. To check the scanner pool, run the `vserver vscan scanner-pool show` command on the storage system command prompt. If the Vscan servers still cannot connect, there might be an issue with the network.
Clients observe high latency.	It is probably time to add more Vscan servers to the scanner pool.
Too many scans are triggered.	Modify the value of the `vscan-fileop-profile` parameter to restrict the number of file operations monitored for virus scanning.
Some files are not being scanned.	Check the on-access policy. It is possible that the path for these files has been added to the path-exclusion list or that their size exceeds the configured value for exclusions. To check the on-access policy, run the `vserver vscan on-access-policy show` command on the storage system command prompt.
File access is denied.	Check whether the *scan-mandatory* setting is specified in the policy configuration. This setting denies data access if no Vscan servers are connected. Modify the setting as needed.

Monitor ONTAP Vscan status and performance activities

You can monitor the critical aspects of the Vscan module, such as the Vscan server connection status,
the health of the Vscan servers, and the number of files that have been scanned. This information helps
you diagnose issues related to the Vscan server.

View Vscan server connection information

You can view the connection status of Vscan servers to manage the connections that are already in use and the connections that are available for use. Various commands display information about the connection status of Vscan servers.

Command…	Information displayed…

`vserver vscan connection-status show`	Summary of the connection status
`vserver vscan connection-status show-all`	Detailed information about the connection status
`vserver vscan connection-status show-not-connected`	Status of the connections that are available but not connected
`vserver vscan connection-status show-connected`	Information about the connected Vscan server

Learn more about `vserver vscan connection-status show` in the ONTAP command reference.

View Vscan server statistics

You can view Vscan server–specific statistics to monitor performance and diagnose issues related to virus scanning. You must collect a data sample before you can use the `statistics show` command to display the Vscan server statistics.

Learn more about `statistics show` in the ONTAP command reference.

To complete a data sample, complete the following step:

Step

1. Run the `statistics start` command and the optional `statistics stop` command.

   Learn more about `statistics start` and `statistics stop` in the ONTAP command reference.

View statistics for Vscan server requests and latencies

You can use ONTAP `offbox_vscan` counters on a per-SVM basis to monitor the rate of Vscan server requests that are dispatched and received per second and the server latencies across all Vscan servers. To view these statistics, complete the following step:

Step

1. Run the `statistics show -object offbox_vscan –instance SVM` command with the following counters:

Counter…	Information displayed…
`scan_request_dispatched_rate`	Number of virus-scanning requests sent from ONTAP to the Vscan servers per second
`scan_noti_received_rate`	Number of virus-scanning requests received back by ONTAP from the Vscan servers per second

`dispatch_latency`	Latency within ONTAP to identify an available Vscan server and send the request to that Vscan server
`scan_latency`	Round-trip latency from ONTAP to the Vscan server, including the time for the scan to run

Example of statistics generated from an ONTAP offbox vscan counter

```
Object: offbox_vscan
Instance: SVM
Start-time: 10/16/2013 10:13:25
End-time: 10/16/2013 10:25:11
Cluster: cluster01
Number of Constituents: 2 (complete_aggregation)
Counter Value
-------------------------------- --------------------------------
scan_request_dispatched_rate 291
scan_noti_received_rate 292
dispatch_latency 43986us
scan_latency 3433501us
-----------------------------------------------------------------
```

View statistics for individual Vscan server requests and latencies

You can use ONTAP `offbox_vscan_server` counters on a per-SVM, per–off-box Vscan server, and per-node basis to monitor the rate of dispatched Vscan server requests and the server latency on each Vscan server individually. To collect this information, complete the following step:

Step

1. Run the `statistics show -object offbox_vscan -instance SVM:servername:nodename` command with the following counters:

Counter…	Information displayed…
`scan_request_dispatched_rate`	Number of virus-scanning requests sent from ONTAP
`scan_latency`	Round-trip latency from ONTAP to the Vscan server, including the time for the scan to run to the Vscan servers per second

Example of statistics generated from an ONTAP offbox_vscan_server counter

```
Object: offbox_vscan_server
Instance: SVM:vscan_server:node
Start-time: 10/16/2013 10:13:25
End-time: 10/16/2013 10:25:11
Cluster: cluster01
Number of Constituents: 1 (complete_aggregation)
Counter Value
-------------------------------- --------------------------------
scan_request_dispatched_rate 291
scan_latency 3433830us
------------------------------------------------------------------
```

View statistics for Vscan server utilization

You can also use ONTAP `offbox_vscan_server` counters to collect Vscan server–side utilization statistics. These statistics are tracked on a per-SVM, per–off-box Vscan server, and per-node basis. They include CPU utilization on the Vscan server, queue depth for scanning operations on the Vscan server (both current and maximum), used memory and used network.
These statistics are forwarded by the Antivirus Connector to the statistics counters within ONTAP. They are based on data that is polled every 20 seconds and must be collected multiple times for accuracy; otherwise, the values seen in the statistics reflect only the last polling. CPU utilization and queues are particularly important to monitor and analyze. A high value for an average queue can indicate that the Vscan server has a bottleneck.
To collect utilization statistics for the Vscan server on a per-SVM, per–off-box Vscan server, and per-node basis, complete the following step:

Step

1. Collect utilization statistics for the Vscan server

   Run the `statistics show -object offbox_vscan_server -instance SVM:servername:nodename` command with the following `offbox_vscan_server` counters:

Counter…	**Information displayed…**
`scanner_stats_pct_cpu_used`	CPU utilization on the Vscan server
`scanner_stats_pct_input_queue_avg`	Average queue of scan requests on the Vscan server
`scanner_stats_pct_input_queue_hiwatermark`	Peak queue of scan requests on the Vscan server
`scanner_stats_pct_mem_used`	Memory used on the Vscan server
`scanner_stats_pct_network_used`	Network used on the Vscan server

Example of utilization statistics for the Vscan server

```
Object: offbox_vscan_server
Instance: SVM:vscan_server:node
Start-time: 10/16/2013 10:13:25
End-time: 10/16/2013 10:25:11
Cluster: cluster01
Number of Constituents: 1 (complete_aggregation)
Counter Value
-------------------------------- --------------------------------
scanner_stats_pct_cpu_used 51
scanner_stats_pct_dropped_requests 0
scanner_stats_pct_input_queue_avg 91
scanner_stats_pct_input_queue_hiwatermark 100
scanner_stats_pct_mem_used 95
scanner_stats_pct_network_used 4
-----------------------------------------------------------------
```

Audit NAS events on SVMs

Learn about auditing file access using ONTAP for both the SMB and NFS protocols

You can use the file access auditing features available for the SMB and NFS protocols with ONTAP, such as native auditing and file policy management using FPolicy.

You should design and implement auditing of SMB and NFS file access events under the following circumstances:

- Basic SMB and NFS protocol file access has been configured.
- You want to create and maintain an auditing configuration using one of the following methods:
    - Native ONTAP functionality
    - External FPolicy servers

Audit NAS events on SVMs

Auditing for NAS events is a security measure that enables you to track and log certain SMB and NFS events on storage virtual machines (SVMs). This helps you track potential security problems and provides evidence of any security breaches. You can also stage and audit Active Directory central access policies to see what the result of implementing them would be.

SMB events

You can audit the following events:

- SMB file and folder access events

  You can audit SMB file and folder access events on objects stored on FlexVol volumes belonging to the auditing-enabled SVMs.

- SMB logon and logoff events

  You can audit SMB logon and logoff events for SMB servers on SVMs.

- Central access policy staging events

  You can audit the effective access of objects on SMB servers using permissions applied through proposed central access policies. Auditing through the staging of central access policies enables you to see what the effects are of central access policies before they are deployed.

  Auditing of central access policy staging is set up using Active Directory GPOs; however, the SVM auditing configuration must be configured to audit central access policy staging events.

  Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, central access policy staging events are generated only if Dynamic Access Control is enabled. Dynamic Access Control is enabled through a SMB server option. It is not enabled by default.

NFS events

You can audit file and directory events by utilizing NFSv4 ACL's on objects stored on SVMs.

How auditing works

Learn the fundamental ONTAP auditing concepts

To understand auditing in ONTAP, you should be aware of some basic auditing concepts.

- **Staging files**

  The intermediate binary files on individual nodes where audit records are stored prior to consolidation and conversion. Staging files are contained in staging volumes.

- **Staging volume**

  A dedicated volume created by ONTAP to store staging files. There is one staging volume per aggregate. Staging volumes are shared by all audit-enabled storage virtual machines (SVMs) to store audit records of data access for data volumes in that particular aggregate. Each SVM's audit records are stored in a separate directory within the staging volume.

  Cluster administrators can view information about staging volumes, but most other volume operations are not permitted. Only ONTAP can create staging volumes. ONTAP automatically assigns a name to staging volumes. All staging volume names begin with `MDV_aud_` followed by the UUID of the aggregate containing that staging volume (for example: `MDV_aud_1d0131843d4811e296fc123478563412`.)

- **System volumes**

  A FlexVol volume that contains special metadata, such as metadata for file services audit logs. The admin SVM owns system volumes, which are visible across the cluster. Staging volumes are a type of system volume.

- **Consolidation task**

  A task that gets created when auditing is enabled. This long-running task on each SVM takes the audit records from staging files across the member nodes of the SVM. This task merges the audit records in sorted chronological order, and then converts them to a user-readable event log format specified in the auditing configuration—either the EVTX or XML file format. The converted event logs are stored in the audit event log directory that is specified in the SVM auditing configuration.

Learn about the functioning of the ONTAP auditing process

The ONTAP auditing process is different from the Microsoft auditing process. Before you configure auditing, you should understand how the ONTAP auditing process works.

Audit records are initially stored in binary staging files on individual nodes. If auditing is enabled on an SVM, every member node maintains staging files for that SVM. Periodically, they are consolidated and converted to user-readable event logs, which are stored in the audit event log directory for the SVM.

Process when auditing is enabled on an SVM

Auditing can only be enabled on SVMs. When the storage administrator enables auditing on the SVM, the auditing subsystem checks whether staging volumes are present. A staging volume must exist for each aggregate that contains data volumes owned by the SVM. The auditing subsystem creates any needed staging volumes if they do not exist.

The auditing subsystem also completes other prerequisite tasks before auditing is enabled:

- The auditing subsystem verifies that the log directory path is available and does not contain symlinks.

  The log directory must already exist as a path within the SVM's namespace. It is recommended to create a new volume or qtree to hold the audit log files. The auditing subsystem does not assign a default log file location. If the log directory path specified in the auditing configuration is not a valid path, auditing configuration creation fails with the `The specified path "/path" does not exist in the namespace belonging to Vserver "Vserver_name"` error.

  Configuration creation fails if the directory exists but contains symlinks.

- Auditing schedules the consolidation task.

  After this task is scheduled, auditing is enabled. The SVM auditing configuration and the log files persist across a reboot or if the NFS or SMB servers are stopped or restarted.

Event log consolidation

Log consolidation is a scheduled task that runs on a routine basis until auditing is disabled. When auditing is disabled, the consolidation task verifies that all of the remaining logs are consolidated.

Guaranteed auditing

By default, auditing is guaranteed. ONTAP guarantees that all auditable file access events (as specified by configured audit policy ACLs) are recorded, even if a node is unavailable. A requested file operation cannot be completed until the audit record for that operation is saved to the staging volume on persistent storage. If audit records cannot be committed to the disk in the staging files, either because of insufficient space or because of other issues, client operations are denied.

> An administrator, or account user with privilege level access, can bypass the file audit logging operation by using NetApp Manageability SDK or REST APIs. You can determine if any file actions have been taken using NetApp Manageability SDK or REST APIs by reviewing the command history logs stored in the `audit.log` file.
>
> For more information about command history audit logs, see the "Managing audit logging for management activities" section in System administration.

Consolidation process when a node is unavailable

If a node containing volumes belonging to an SVM with auditing enabled is unavailable, the behavior of the auditing consolidation task depends on whether the node's storage failover (SFO) partner (or the HA partner in the case of a two-node cluster) is available:

- If the staging volume is available through the SFO partner, the staging volumes last reported from the node are scanned, and consolidation proceeds normally.
- If the SFO partner is not available, the task creates a partial log file.

  When a node is not reachable, the consolidation task consolidates the audit records from the other available nodes of that SVM. To identify that it is not complete, the task adds the suffix `.partial` to the consolidated file name.
- After the unavailable node is available, the audit records in that node are consolidated with the audit records from the other nodes at that time.
- All audit records are preserved.

Event log rotation

Audit event log files are rotated when they reach a configured threshold log size or on a configured schedule. When an event log file is rotated, the scheduled consolidation task first renames the active converted file to a time-stamped archive file, and then creates a new active converted event log file.

Process when auditing is disabled on the SVM

When auditing is disabled on the SVM, the consolidation task is triggered one final time. All outstanding, recorded audit records are logged in a user-readable format. Existing event logs stored in the event log directory are not deleted when auditing is disabled on the SVM and are available for viewing.

After all existing staging files for that SVM are consolidated, the consolidation task is removed from the schedule. Disabling the auditing configuration for the SVM does not remove the auditing configuration. A storage administrator can reenable auditing at any time.

The auditing consolidation job, which gets created when auditing is enabled, monitors the consolidation task and re-creates it if the consolidation task exits because of an error. Users cannot delete the auditing consolidation job.

Prerequisites for ONTAP auditing

Before you configure and enable auditing on your storage virtual machine (SVM), you need to be aware of certain requirements and considerations.

- The combined limit for NFS and S3 auditing-enabled SVMs depends on your version of ONTAP:

ONTAP version	Maximum
9.8 and earlier	50
9.9.1 and later	400

- Auditing is not tied to SMB or NFS licensing.

  You can configure and enable auditing even if SMB and NFS licenses are not installed on the cluster.

- NFS auditing supports security ACEs (type U).
- For NFS auditing, there is no mapping between mode bits and auditing ACEs.

  When converting ACLs to mode bits, auditing ACEs are skipped. When converting mode bits to ACLs, auditing ACEs are not generated.

- The directory specified in the auditing configuration must exist.

  If it does not exist, the command to create the auditing configuration fails.

- The directory specified in the auditing configuration must meet the following requirements:
  - The directory must not contain symbolic links.

    If the directory specified in the auditing configuration contains symbolic links, the command to create the auditing configuration fails.

  - You must specify the directory by using an absolute path.

    You should not specify a relative path, for example, `/vs1/../`.

- Auditing is dependent on having available space in the staging volumes.

  You must be aware of and have a plan for ensuring that there is sufficient space for the staging volumes in aggregates that contain audited volumes.

- Auditing is dependent on having available space in the volume containing the directory where converted event logs are stored.

  You must be aware of and have a plan for ensuring that there is sufficient space in the volumes used to store event logs. You can specify the number of event logs to retain in the auditing directory by using the `-rotate-limit` parameter when creating an auditing configuration, which can help to ensure that there is enough available space for the event logs in the volume.

- Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, Dynamic Access Control must be enabled to generate central access policy staging events.

  Dynamic Access Control is not enabled by default.

Aggregate space considerations when enabling auditing

When an auditing configuration is created and auditing is enabled on at least one storage virtual machine

(SVM) in the cluster, the auditing subsystem creates staging volumes on all existing aggregates and on all new aggregates that are created. You need to be aware of certain aggregate space considerations when you enable auditing on the cluster.

Staging volume creation might fail due to non-availability of space in an aggregate. This might happen if you create an auditing configuration and existing aggregates do not have enough space to contain the staging volume.

You should ensure that there is enough space on existing aggregates for the staging volumes before enabling auditing on an SVM.

Limitations on the size of staging files for ONTAP audit records

The size of an audit record on a staging file cannot be greater than 32 KB.

When large audit records can occur

Large audit records might occur during management auditing in one of the following scenarios:

- Adding or deleting users to or from groups with a large number of users.
- Adding or deleting a file-share access control list (ACL) on a file-share with a large number of file-share users.
- Other scenarios.

Disable management auditing to avoid this issue. To do this, modify the audit configuration and remove the following from the list of audit event types:

- file-share
- user-account
- security-group
- authorization-policy-change

  After removal, they will not be audited by the file services auditing subsystem.

The effects of audit records that are too large

- If the size of an audit record is too large (over 32 KB), the audit record is not created and the auditing subsystem generates an event management system (EMS) message similar to the following:

  ```
  File Services Auditing subsystem failed the operation or truncated an audit
  record because it was greater than max_audit_record_size value. Vserver
  UUID=%s, event_id=%u, size=%u
  ```

  If auditing is guaranteed, the file operation fails because its audit record cannot be created.

- If the size of the audit record is more than 9,999 bytes, the same EMS message as above is displayed. A partial audit record is created with the larger key value missing.
- If the audit record exceeds 2,000 characters, the following error message shows instead of the actual value:

  ```
  The value of this field was too long to display.
  ```

Learn about the supported formats for ONTAP audit event logs

Supported file formats for the converted audit event logs are `EVTX` and `XML` file formats.

You can specify the type of file format when you create the auditing configuration. By default, ONTAP converts the binary logs to the `EVTX` file format.

View and process ONTAP audit event logs

You can use audit event logs to determine whether you have adequate file security and whether there have been improper file and folder access attempts. You can view and process audit event logs saved in the `EVTX` or `XML` file formats.

- `EVTX` file format

  You can open the converted `EVTX` audit event logs as saved files using Microsoft Event Viewer.

  There are two options that you can use when viewing event logs using Event Viewer:

  - General view

    Information that is common to all events is displayed for the event record. In this version of ONTAP, the event-specific data for the event record is not displayed. You can use the detailed view to display event-specific data.

  - Detailed view

    A friendly view and an XML view are available. The friendly view and the XML view display both the information that is common to all events and the event-specific data for the event record.

- `XML` file format

  You can view and process `XML` audit event logs on third-party applications that support the `XML` file format. XML viewing tools can be used to view the audit logs provided you have the XML schema and information about definitions for the XML fields. For more information about the XML schema and definitions, see the ONTAP Auditing Schema Reference.

How active audit logs are viewed using Event Viewer

If the audit consolidation process is running on the cluster, the consolidation process appends new records to the active audit log file for audit-enabled storage virtual machines (SVMs). This active audit log can be accessed and opened over an SMB share in Microsoft Event Viewer.

In addition to viewing existing audit records, Event Viewer has a refresh option that enables you to refresh the content in the console window. Whether the newly appended logs are viewable in Event Viewer depends on whether oplocks are enabled on the share used to access the active audit log.

Oplocks setting on the share	Behavior
Enabled	Event Viewer opens the log that contains events written to it up to that point in time. The refresh operation does not refresh the log with new events appended by the consolidation process.

Disabled	Event Viewer opens the log that contains events written to it up to that point in time. The refresh operation refreshes the log with new events appended by the consolidation process.

This information is applicable only for `EVTX` event logs. `XML` event logs can be viewed through SMB in a browser or through NFS using any XML editor or viewer.

SMB events that can be audited

Learn about SMB events that ONTAP can audit to interpret results

ONTAP can audit certain SMB events, including certain file and folder access events, certain logon and logoff events, and central access policy staging events. Knowing which access events can be audited is helpful when interpreting results from the event logs.

The following additional SMB events can be audited:

Event ID (EVT/EVTX)	Event	Description	Category
4670	Object permissions were changed	OBJECT ACCESS: Permissions changed.	File Access
4907	Object auditing settings were changed	OBJECT ACCESS: Audit settings changed.	File Access
4913	Object Central Access Policy was changed	OBJECT ACCESS: CAP changed.	File Access

The following SMB events can be audited in ONTAP 9.0 and later:

Event ID (EVT/EVTX)	Event	Description	Category
540/4624	An account was successfully logged on	LOGON/LOGOFF: Network (SMB) logon.	Logon and Logoff
529/4625	An account failed to log on	LOGON/LOGOFF: Unknown user name or bad password.	Logon and Logoff
530/4625	An account failed to log on	LOGON/LOGOFF: Account logon time restriction.	Logon and Logoff
531/4625	An account failed to log on	LOGON/LOGOFF: Account currently disabled.	Logon and Logoff

532/4625	An account failed to log on	LOGON/LOGOFF: User account has expired.	Logon and Logoff
533/4625	An account failed to log on	LOGON/LOGOFF: User cannot log on to this computer.	Logon and Logoff
534/4625	An account failed to log on	LOGON/LOGOFF: User not granted logon type here.	Logon and Logoff
535/4625	An account failed to log on	LOGON/LOGOFF: User’s password has expired.	Logon and Logoff
537/4625	An account failed to log on	LOGON/LOGOFF: Logon failed for reasons other than above.	Logon and Logoff
539/4625	An account failed to log on	LOGON/LOGOFF: Account locked out.	Logon and Logoff
538/4634	An account was logged off	LOGON/LOGOFF: Local or network user logoff.	Logon and Logoff
560/4656	Open Object/Create Object	OBJECT ACCESS: Object (file or directory) open.	File Access
563/4659	Open Object with the Intent to Delete	OBJECT ACCESS: A handle to an object (file or directory) was requested with the Intent to Delete.	File Access
564/4660	Delete Object	OBJECT ACCESS: Delete Object (file or directory). ONTAP generates this event when a Windows client attempts to delete the object (file or directory).	File Access
567/4663	Read Object/Write Object/Get Object Attributes/Set Object Attributes	OBJECT ACCESS: Object access attempt (read, write, get attribute, set attribute). **Note:** For this event, ONTAP audits only the first SMB read and first SMB write operation (success or failure) on an object. This prevents ONTAP from creating excessive log entries when a single client opens an object and performs many successive read or write operations to the same object.	File Access

NA/4664	Hard link	OBJECT ACCESS: An attempt was made to create a hard link.	File Access
NA/4818	Proposed central access policy does not grant the same access permissions as the current central access policy	OBJECT ACCESS: Central Access Policy Staging.	File Access
NA/NA Data ONTAP Event ID 9999	Rename Object	OBJECT ACCESS: Object renamed. This is an ONTAP event. It is not currently supported by Windows as a single event.	File Access
NA/NA Data ONTAP Event ID 9998	Unlink Object	OBJECT ACCESS: Object unlinked. This is an ONTAP event. It is not currently supported by Windows as a single event.	File Access

Additional information about Event 4656

The `HandleID` tag in the audit `XML` event contains the handle of the object (file or directory) accessed. The `HandleID` tag for the EVTX 4656 event contains different information depending on whether the open event is for creating a new object or for opening an existing object:

- If the open event is an open request to create a new object (file or directory), the `HandleID` tag in the audit XML event shows an empty `HandleID` (for example: `<Data Name="HandleID">00000000000000;00;00000000;00000000</Data>`).

  The `HandleID` is empty because the OPEN (for creating a new object) request gets audited before the actual object creation happens and before a handle exists. Subsequent audited events for the same object have the right object handle in the `HandleID` tag.

- If the open event is an open request to open an existing object, the audit event will have the assigned handle of that object in the `HandleID` tag (for example: `<Data Name="HandleID">00000000000401;00;000000ea;00123ed4</Data>`).

Determine the complete path to the ONTAP audited object

The object path printed in the `<ObjectName>` tag for an audit record contains the name of the volume (in parentheses) and the relative path from the root of the containing volume. If you want to determine the complete path of the audited object, including the junction path, there are certain steps you must take.

Steps

1. Determine what the volume name and relative path to audited object is by looking at the `<ObjectName>` tag in the audit event.

   In this example, the volume name is “data1” and the relative path to the file is `/dir1/file.txt`:

<Data Name="ObjectName"> (data1);/dir1/file.txt </Data>

2. Using the volume name determined in the previous step, determine what the junction path is for the volume containing the audited object:

   In this example, the volume name is “data1” and the junction path for the volume containing the audited object is `/data/data1`:

   `volume show -junction -volume data1`

```
                                          Junction                      Junction
Vserver   Volume       Language Active    Junction Path     Path Source
--------- ------------ -------- --------  ----------------- -----------
vs1       data1        en_US.UTF-8
                                  true      /data/data1       RW_volume
```

3. Determine the full path to the audited object by appending the relative path found in the `<ObjectName>` tag to the junction path for the volume.

   In this example, the junction path for the volume:

   `/data/data1/dir1/file.text`

Learn about ONTAP auditing of symlinks and hard links

There are certain considerations you must keep in mind when auditing symlinks and hard links.

An audit record contains information about the object being audited including the path to the audited object, which is identified in the `ObjectName` tag. You should be aware of how paths for symlinks and hard links are recorded in the `ObjectName` tag.

Symlinks

A symlink is a file with a separate inode that contains a pointer to the location of a destination object, known as the target. When accessing an object through a symlink, ONTAP automatically interprets the symlink and follows the actual canonical protocol agnostic path to the target object in the volume.

In the following example output, there are two symlinks, both pointing to a file named `target.txt`. One of the symlinks is a relative symlink and one is an absolute symlink. If either of the symlinks are audited, the `ObjectName` tag in the audit event contains the path to the file `target.txt`:

```
[root@host1 audit]# ls -l
total 0
lrwxrwxrwx 1 user1 group1 37 Apr  2 10:09 softlink_fullpath.txt ->
/data/audit/target.txt
lrwxrwxrwx 1 user1 group1 10 Apr  2 09:54 softlink.txt -> target.txt
-rwxrwxrwx 1 user1 group1 16 Apr  2 10:05 target.txt
```

Hard links

A hard link is a directory entry that associates a name with an existing file on a file system. The hard link points to the inode location of the original file. Similar to how ONTAP interprets symlinks, ONTAP interprets the hard link and follows the actual canonical path to the target object in the volume. When access to a hard link object is audited, the audit event records this absolute canonical path in the `ObjectName` tag rather than the hard link path.

Learn about ONTAP auditing of alternate NTFS data streams

There are certain considerations you must keep in mind when auditing files with NTFS alternate data streams.

The location of an object being audited is recorded in an event record using two tags, the `ObjectName` tag (the path) and the `HandleID` tag (the handle). To properly identify which stream requests are being logged, you must be aware of what ONTAP records in these fields for NTFS alternate data streams:

- EVTX ID: 4656 events (open and create audit events)
    - The path of the alternate data stream is recorded in the `ObjectName` tag.
    - The handle of the alternate data stream is recorded in the `HandleID` tag.
- EVTX ID: 4663 events (all other audit events, such as read, write, getattr, and so on)
    - The path of the base file, not the alternate data stream, is recorded in the `ObjectName` tag.
    - The handle of the alternate data stream is recorded in the `HandleID` tag.

Example

The following example illustrates how to identify EVTX ID: 4663 events for alternate data streams using the `HandleID` tag. Even though the `ObjectName` tag (path) recorded in the read audit event is to the base file path, the `HandleID` tag can be used to identify the event as an audit record for the alternate data stream.

Stream file names take the form `base_file_name:stream_name`. In this example, the `dir1` directory contains a base file with an alternate data stream having the following paths:

```
/dir1/file1.txt
/dir1/file1.txt:stream1
```

> ⓘ The output in the following event example is truncated as indicated; the output does not display all of the available output tags for the events.

For an EVTX ID 4656 (open audit event), the audit record output for the alternate data stream records the alternate data stream name in the `ObjectName` tag:

```
- <Event>
- <System>
  <Provider Name="Netapp-Security-Auditing" />
  <EventID>4656</EventID>
  <EventName>Open Object</EventName>
  [...]
  </System>
- <EventData>
  [...]
  **<Data Name="ObjectType"\>Stream</Data\>
  <Data Name="HandleID"\>00000000000401;00;000001e4;00176767</Data\>
  <Data Name="ObjectName"\>\(data1\);/dir1/file1.txt:stream1</Data\>
**
  [...]
  </EventData>
  </Event>
- <Event>
```

For an EVTX ID 4663 (read audit event), the audit record output for the same alternate data stream records the base file name in the `ObjectName` tag; however, the handle in the `HandleID` tag is the alternative data stream's handle and can be used to correlate this event with the alternative data stream:

```
- <Event>
- <System>
  <Provider Name="Netapp-Security-Auditing" />
  <EventID>4663</EventID>
  <EventName>Read Object</EventName>
  [...]
  </System>
- <EventData>
  [...]
  **<Data Name="ObjectType"\>Stream</Data\>
  <Data Name="HandleID"\>00000000000401;00;000001e4;00176767</Data\>
  <Data Name="ObjectName"\>\(data1\);/dir1/file1.txt</Data\> **
  [...]
  </EventData>
  </Event>
- <Event>
```

Learn about ONTAP auditing of NFS file and directory access events

ONTAP can audit certain NFS file and directory access events. Knowing what access events can be audited is helpful when interpreting results from the converted audit event logs.

You can audit the following NFS file and directory access events:

- READ
- OPEN
- CLOSE
- READDIR
- WRITE
- SETATTR
- CREATE
- LINK
- OPENATTR
- REMOVE
- GETATTR
- VERIFY
- NVERIFY
- RENAME

To reliably audit NFS RENAME events, you should set audit ACEs on directories instead of files because file permissions are not checked for a RENAME operation if the directory permissions are sufficient.

Plan the auditing configuration on ONTAP SVMs

Before you configure auditing on storage virtual machines (SVMs), you must understand which configuration options are available and plan the values that you want to set for each option. This information can help you configure the auditing configuration that meets your business needs.

There are certain configuration parameters that are common to all auditing configurations.

Additionally, there are certain parameters that you can use to specify which methods are used when rotating the consolidated and converted audit logs. You can specify one of the three following methods when you configure auditing:

- Rotate logs based on log size

  This is the default method used to rotate logs.

- Rotate logs based on a schedule
- Rotate logs based on log size and schedule (whichever event occurs first)

> At least one of the methods for log rotation should always be set.

Parameters common to all auditing configurations

There are two required parameters that you must specify when you create the auditing configuration. There are also three optional parameters that you can specify:

Type of information	Option	Required	Include	Your values
SVM name Name of the SVM on which to create the auditing configuration. The SVM must already exist.	`-vserver` `vserver_name`	Yes	Yes	
Log destination path Specifies the directory where the converted audit logs are stored, typically a dedicated volume or qtree. The path must already exist in the SVM namespace. The path can be up to 864 characters in length and must have read-write permissions. If the path is not valid, the audit configuration command fails. If the SVM is an SVM disaster recovery source, the log destination path cannot be on the root volume. This is because root volume content is not replicated to the disaster recovery destination. You cannot use a FlexCache volume as a log destination (ONTAP 9.7 and later).	`-destination` `text`	Yes	Yes	

Categories of events to audit Specifies the categories of events to audit. The following event categories can be audited: • File access events (both SMB and NFSv4) • SMB logon and logoff events • Central access policy staging events Central access policy staging events are available beginning with Windows 2012 Active Directory domains. • Async-delete • File share category events • Audit policy change events • Local user account management events • Security group management events • Authorization policy change events The default is to audit file access and SMB logon and logoff events. **Note:** Before you can specify `cap-staging` as an event category, a SMB server must exist on the SVM. Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, central access policy staging events are generated only if Dynamic Access Control is enabled. Dynamic Access Control is enabled through a SMB server option. It is not enabled by default.	`-events {file-ops|cifs-logon-logoff|cap-staging|file-share|audit-policy-change|user-account|security-group|authorization-policy-change|async-delete}`	No		
Log file output format Determines the output format of the audit logs. The output format can be either ONTAP-specific `XML` or Microsoft Windows `EVTX` log format. By default, the output format is `EVTX`.	`-format {xml|evtx}`	No		

Log files rotation limit Determines how many audit log files to retain before rotating the oldest log file out. For example, if you enter a value of `5`, the last five log files are retained. A value of `0` indicates that all the log files are retained. The default value is 0.	`-rotate-limit integer`	No		

Parameters used for determining when to rotate audit event logs

Rotate logs based on log size

The default is to rotate audit logs based on size.

- The default log size is 100 MB
- If you want to use the default log rotation method and the default log size, you do not need to configure any specific parameters for log rotation.
- If you want to rotate the audit logs based on a log size alone, use the following command to unset the `-rotate-schedule-minute` parameter: `vserver audit modify -vserver vs0 -destination / -rotate-schedule-minute -`

If you do not want to use the default log size, you can configure the `-rotate-size` parameter to specify a custom log size:

Type of information	Option	Required	Include	Your values
Log file size limit Determines the audit log file size limit.	`-rotate-size {integer`[KB|MB|GB|TB|PB]}	No		

Rotate logs based on a schedule

If you choose to rotate the audit logs based on a schedule, you can schedule log rotation by using the time-based rotation parameters in any combination.

- If you use time-based rotation, the `-rotate-schedule-minute` parameter is mandatory.
- All other time-based rotation parameters are optional.
- The rotation schedule is calculated by using all the time-related values.

  For example, if you specify only the `-rotate-schedule-minute` parameter, the audit log files are rotated based on the minutes specified on all days of the week, during all hours on all months of the year.

- If you specify only one or two time-based rotation parameters (for example, `-rotate-schedule-month` and `-rotate-schedule-minutes`), the log files are rotated based on the minute values that you specified on all days of the week, during all hours, but only during the specified months.

  For example, you can specify that the audit log is to be rotated during the months January, March, and

August on all Mondays, Wednesdays, and Saturdays at 10:30 a.m.

- If you specify values for both `-rotate-schedule-dayofweek` and `-rotate-schedule-day`, they are considered independently.

  For example, if you specify `-rotate-schedule-dayofweek` as Friday and `-rotate-schedule-day` as 13, then the audit logs would be rotated on every Friday and on the 13th day of the specified month, not just on every Friday the 13th.

- If you want to rotate the audit logs based on a schedule alone, use the following command to unset the `-rotate-size` parameter: `vserver audit modify -vserver vs0 -destination / -rotate -size -`

You can use the following list of available auditing parameters to determine what values to use for configuring a schedule for audit event log rotations:

Type of information	Option	Required	Include	Your values
Log rotation schedule: Month Determines the monthly schedule for rotating audit logs. Valid values are `January` through `December`, and `all`. For example, you can specify that the audit log is to be rotated during the months January, March, and August.	`-rotate-schedule-month chron_month`	No		
Log rotation schedule: Day of week Determines the daily (day of week) schedule for rotating audit logs. Valid values are `Sunday` through `Saturday`, and `all`. For example, you can specify that the audit log is to be rotated on Tuesdays and Fridays, or during all the days of a week.	`-rotate-schedule -dayofweek chron_dayofweek`	No		
Log rotation schedule: Day Determines the day of the month schedule for rotating the audit log. Valid values range from `1` through `31`. For example, you can specify that the audit log is to be rotated on the 10th and 20th days of a month, or all days of a month.	`-rotate-schedule-day chron_dayofmonth`	No		

Log rotation schedule: Hour Determines the hourly schedule for rotating the audit log. Valid values range from `0` (midnight) to `23` (11:00 p.m.). Specifying `all` rotates the audit logs every hour. For example, you can specify that the audit log is to be rotated at 6 (6 a.m.) and 18 (6 p.m.).	`-rotate-schedule-hour chron_hour`	No		
Log rotation schedule: Minute Determines the minute schedule for rotating the audit log. Valid values range from `0` to `59`. For example, you can specify that the audit log is to be rotated at the 30th minute.	`-rotate-schedule-minute chron_minute`	Yes, if configuring schedule-based log rotation; otherwise, no.		

Rotate logs based on log size and schedule

You can choose to rotate the log files based on log size and a schedule by setting both the `-rotate-size` parameter and the time-based rotation parameters in any combination. For example: if `-rotate-size` is set to 10 MB and `-rotate-schedule-minute` is set to 15, the log files rotate when the log file size reaches 10 MB or on the 15th minute of every hour (whichever event occurs first).

Create a file and directory auditing configuration on SVMs

Create file and directory auditing configuration on ONTAP SVMs

Creating a file and directory auditing configuration on your storage virtual machine (SVM) includes understanding the available configuration options, planning the configuration, and then configuring and enabling the configuration. You can then display information about the auditing configuration to confirm that the resultant configuration is the desired configuration.

Before you can begin auditing file and directory events, you must create an auditing configuration on the storage virtual machine (SVM).

Before you begin

If you plan on creating an auditing configuration for central access policy staging, a SMB server must exist on the SVM.

- Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, central access policy staging events are generated only if Dynamic Access Control is enabled.

  Dynamic Access Control is enabled through a SMB server option. It is not enabled by default.

- If the arguments of a field in a command is invalid, for example, invalid entries for fields, duplicate entries, and non-existent entries, then the command fails before the audit phase.

  Such failures do not generate an audit record.

About this task

If the SVM is an SVM disaster recovery source, the destination path cannot be on the root volume.

Step

1. Using the information in the planning worksheet, create the auditing configuration to rotate audit logs based on log size or a schedule:

If you want to rotate audit logs by…	Enter…
Log size	`vserver audit create -vserver vserver_name -destination path -events [{file-ops|cifs-logon-logoff|cap-staging|file-share|authorization-policy-change|user-account|security-group|authorization-policy-change}] [-format {xml|evtx}] [-rotate-limit integer] [-rotate-size {integer[KB|MB|GB|TB|PB]}]`
A schedule	`vserver audit create -vserver vserver_name -destination path -events [{file-ops|cifs-logon-logoff|cap-staging}] [-format {xml|evtx}] [-rotate-limit integer] [-rotate-schedule-month chron_month] [-rotate-schedule-dayofweek chron_dayofweek] [-rotate-schedule-day chron_dayofmonth] [-rotate-schedule-hour chron_hour] -rotate-schedule-minute chron_minute`  The `-rotate-schedule-minute` parameter is required if you are configuring time-based audit log rotation.

Examples

The following example creates an auditing configuration that audits file operations and SMB logon and logoff events (the default) using size-based rotation. The log format is `EVTX` (the default). The logs are stored in the `/audit_log` directory. The log file size limit is `200 MB`. The logs are rotated when they reach 200 MB in size:

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log
-rotate-size 200MB
```

The following example creates an auditing configuration that audits file operations and SMB logon and logoff events (the default) using size-based rotation. The log format is `EVTX` (the default). The logs are stored in the `/cifs_event_logs` directory. The log file size limit is `100 MB` (the default), and the log rotation limit is `5`:

```
cluster1::> vserver audit create -vserver vs1 -destination
/cifs_event_logs -rotate-limit 5
```

The following example creates an auditing configuration that audits file operations, CIFS logon and logoff events, and central access policy staging events using time-based rotation. The log format is `EVTX` (the default). The audit logs are rotated monthly, at 12:30 p.m. on all days of the week. The log rotation limit is `5`:

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log
-events file-ops,cifs-logon-logoff,file-share,audit-policy-change,user-
account,security-group,authorization-policy-change,cap-staging -rotate
-schedule-month all -rotate-schedule-dayofweek all -rotate-schedule-hour
12 -rotate-schedule-minute 30 -rotate-limit 5
```

Related information

- Enable auditing on the SVM
- Verify the auditing configuration

Enable auditing on ONTAP SVMs after setting up auditing configuration

After you finish setting up the auditing configuration, you must enable auditing on the storage virtual machine (SVM).

Before you begin

The SVM audit configuration must already exist.

About this task

When an SVM disaster recovery ID discard configuration is first started (after the SnapMirror initialization is complete) and the SVM has an auditing configuration, ONTAP automatically disables the auditing configuration. Auditing is disabled on the read-only SVM to prevent the staging volumes from filling up. You can enable auditing only after the SnapMirror relationship is broken and the SVM is read-write.

Steps

1. Enable auditing on the SVM:

   `vserver audit enable -vserver vserver_name`

   `vserver audit enable -vserver vs1`

Related information

- Create the auditing configuration
- Verify the auditing configuration

Verify the ONTAP auditing configuration

After completing the auditing configuration, you should verify that auditing is configured properly and is enabled.

Steps

1. Verify the auditing configuration:

   `vserver audit show -instance -vserver vserver_name`

   The following command displays in list form all auditing configuration information for storage virtual machine (SVM) vs1:

   `vserver audit show -instance -vserver vs1`

```
                                 Vserver: vs1
                          Auditing state: true
                    Log Destination Path: /audit_log
           Categories of Events to Audit: file-ops
                              Log Format: evtx
                     Log File Size Limit: 200MB
            Log Rotation Schedule: Month: -
      Log Rotation Schedule: Day of Week: -
              Log Rotation Schedule: Day: -
             Log Rotation Schedule: Hour: -
           Log Rotation Schedule: Minute: -
                      Rotation Schedules: -
                Log Files Rotation Limit: 0
```

Related information

- Create the auditing configuration
- Enable auditing on the SVM

Configure file and folder audit policies

Enable auditing configuration on ONTAP SVMs and configure file and folder audit policies

Implementing auditing on file and folder access events is a two-step process. First, you must create and enable an auditing configuration on storage virtual machines (SVMs). Second, you must configure audit policies on the files and folders that you want to monitor. You can configure audit policies to monitor both successful and failed access attempts.

You can configure both SMB and NFS audit policies. SMB and NFS audit policies have different configuration requirements and audit capabilities.

If the appropriate audit policies are configured, ONTAP monitors SMB and NFS access events as specified in the audit policies only if the SMB or NFS servers are running.

Configure ONTAP audit policies on NTFS security-style files and directories

Before you can audit file and directory operations, you must configure audit policies on the files and directories for which you want to collect audit information. This is in addition to setting up and enabling the audit configuration. You can configure NTFS audit policies by using the Windows Security tab or by using the ONTAP CLI.

Configuring NTFS audit policies using the Windows Security tab

You can configure NTFS audit policies on files and directories by using the **Windows Security** tab in the Windows Properties window. This is the same method used when configuring audit policies on data residing on a Windows client, which enables you to use the same GUI interface that you are accustomed to using.

Before you begin

Auditing must be configured on the storage virtual machine (SVM) that contains the data to which you are applying system access control lists (SACLs).

About this task

Configuring NTFS audit policies is done by adding entries to NTFS SACLs that are associated with an NTFS security descriptor. The security descriptor is then applied to NTFS files and directories. These tasks are automatically handled by the Windows GUI. The security descriptor can contain discretionary access control lists (DACLs) for applying file and folder access permissions, SACLs for file and folder auditing, or both SACLs and DACLs.

To set NTFS audit policies using the Windows Security tab, complete the following steps on a Windows host:

Steps

1. From the **Tools** menu in Windows Explorer, select **Map network drive**.
2. Complete the **Map Network Drive** box:

   a. Select a **Drive** letter.

   b. In the **Folder** box, type the SMB server name that contains the share, holding the data you want to audit and the name of the share.

      You can specify the IP address of the data interface for the SMB server instead of the SMB server name.

      If your SMB server name is “SMB_SERVER” and your share is named “share1”, you should enter `\\SMB_SERVER\share1`.

   c. Click **Finish**.

   The drive you selected is mounted and ready with the Windows Explorer window displaying files and folders contained within the share.

3. Select the file or directory for which you want to enable auditing access.
4. Right-click the file or directory, and then select **Properties**.
5. Select the **Security** tab.
6. Click **Advanced**.

7. Select the **Auditing** tab.
8. Perform the desired actions:

If you want to….	Do the following
Set up auditing for a new user or group	a. Click **Add**. b. In the Enter the object name to select box, type the name of the user or group that you want to add. c. Click **OK**.
Remove auditing from a user or group	a. In the Enter the object name to select box, select the user or group that you want to remove. b. Click **Remove**. c. Click **OK**. d. Skip the rest of this procedure.
Change auditing for a user or group	a. In the Enter the object name to select box, select the user or group that you want to change. b. Click **Edit**. c. Click **OK**.

If you are setting up auditing on a user or group or changing auditing on an existing user or group, the Auditing Entry for <object> box opens.

9. In the **Apply to** box, select how you want to apply this auditing entry.

   You can select one of the following:

   - **This folder, subfolders and files**
   - **This folder and subfolders**
   - **This folder only**
   - **This folder and files**
   - **Subfolders and files only**
   - **Subfolders only**
   - **Files only**
     If you are setting up auditing on a single file, the **Apply to** box is not active. The **Apply to** box setting defaults to **This object only**.

   Because auditing takes SVM resources, select only the minimal level that provides the auditing events that meet your security requirements.

10. In the **Access** box, select what you want audited and whether you want to audit successful events, failure events, or both.

    - To audit successful events, select the Success box.
    - To audit failure events, select the Failure box.

Select only the actions that you need to monitor to meet your security requirements. For more information about these auditable events, see your Windows documentation. You can audit the following events:

  - **Full control**
  - **Traverse folder / execute file**
  - **List folder / read data**
  - **Read attributes**
  - **Read extended attributes**
  - **Create files / write data**
  - **Create folders / append data**
  - **Write attributes**
  - **Write extended attributes**
  - **Delete subfolders and files**
  - **Delete**
  - **Read permissions**
  - **Change permissions**
  - **Take ownership**

11. If you do not want the auditing setting to propagate to subsequent files and folders of the original container, select the **Apply these auditing entries to objects and/or containers within this container only** box.
12. Click **Apply**.
13. After you finish adding, removing, or editing auditing entries, click **OK**.

    The Auditing Entry for <object> box closes.

14. In the **Auditing** box, select the inheritance settings for this folder.

    Select only the minimal level that provides the auditing events that meet your security requirements. You can choose one of the following:

    - Select the Include inheritable auditing entries from this object's parent box.
    - Select the Replace all existing inheritable auditing entries on all descendants with inheritable auditing entries from this object box.
    - Select both boxes.
    - Select neither box.
      If you are setting SACLs on a single file, the Replace all existing inheritable auditing entries on all descendants with inheritable auditing entries from this object box is not present in the Auditing box.

15. Click **OK**.

    The Auditing box closes.

Configure NTFS audit policies using the ONTAP CLI

You can configure audit policies on files and folders using the ONTAP CLI. This enables you to configure NTFS audit policies without needing to connect to the data using an SMB share on a Windows client.

You can configure NTFS audit policies by using the `vserver security file-directory` command family.

You can only configure NTFS SACLs using the CLI. Configuring NFSv4 SACLs is not supported with this ONTAP command family.
Learn more about using these commands to configure and add NTFS SACLs to files and folders in the ONTAP command reference.

Configure ONTAP auditing for UNIX security style files and directories

You configure auditing for UNIX security style files and directories by adding audit ACEs to NFSv4.x ACLs. This allows you to monitor certain NFS file and directory access events for security purposes.

About this task

For NFSv4.x, both discretionary and system ACEs are stored in the same ACL. They are not stored in separate DACLs and SACLs. Therefore, you must exercise caution when adding audit ACEs to an existing ACL to avoid overwriting and losing an existing ACL. The order in which you add the audit ACEs to an existing ACL does not matter.

Steps

1. Retrieve the existing ACL for the file or directory by using the `nfs4_getfacl` or equivalent command.

   Learn more about manipulating ACLs in the ONTAP command reference.

2. Append the desired audit ACEs.
3. Apply the updated ACL to the file or directory by using the `nfs4_setfacl` or equivalent command.

Display information about audit policies applied to files and directories

View ONTAP audit policy information by accessing the Windows Security tab

You can display information about audit policies that have been applied to files and directories by using the Security tab in the Windows Properties window. This is the same method used for data residing on a Windows server, which enables customers to use the same GUI interface that they are accustomed to using.

About this task

Displaying information about audit policies applied to files and directories enables you to verify that you have the appropriate system access control lists (SACLs) set on specified files and folders.

To display information about SACLs that have been applied to NTFS files and folders, complete the following steps on a Windows host.

Steps

1. From the **Tools** menu in Windows Explorer, select **Map network drive**.
2. Complete the **Map Network Drive** dialog box:

   a. Select a **Drive** letter.

   b. In the **Folder** box, type the IP address or SMB server name of the storage virtual machine (SVM) containing the share that holds both the data you would like to audit and the name of the share.

If your SMB server name is “SMB_SERVER” and your share is named “share1”, you should enter `\\SMB_SERVER\share1`.

> You can specify the IP address of the data interface for the SMB server instead of the SMB server name.

c. Click **Finish**.

The drive you selected is mounted and ready with the Windows Explorer window displaying files and folders contained within the share.

3. Select the file or directory for which you display auditing information.
4. Right-click on the file or directory, and select **Properties**.
5. Select the **Security** tab.
6. Click **Advanced**.
7. Select the **Auditing** tab.
8. Click **Continue**.

   The Auditing box opens. The **Auditing entries** box displays a summary of users and groups that have SACLs applied to them.

9. In the **Auditing entries** box select the user or group whose SACL entries you want displayed.
10. Click **Edit**.

    The Auditing entry for <object> box opens.

11. In the **Access** box, view the current SACLs that are applied to the selected object.
12. Click **Cancel** to close the **Auditing entry for <object>** box.
13. Click **Cancel** to close the **Auditing** box.

Display information about NTFS audit policies on ONTAP FlexVol volumes

You can display information about NTFS audit policies on FlexVol volumes, including what the security styles and effective security styles are, what permissions are applied, and information about system access control lists. You can use the information to validate your security configuration or to troubleshoot auditing issues.

About this task

Displaying information about audit policies applied to files and directories enables you to verify that you have the appropriate system access control lists (SACLs) set on specified files and folders.

You must provide the name of the storage virtual machine (SVM) and the path to the files or folders whose audit information you want to display. You can display the output in summary form or as a detailed list.

- NTFS security-style volumes and qtrees use only NTFS system access control lists (SACLs) for audit policies.
- Files and folders in a mixed security-style volume with NTFS effective security can have NTFS audit policies applied to them.

Mixed security-style volumes and qtrees can contain some files and directories that use UNIX file permissions, either mode bits or NFSv4 ACLs, and some files and directories that use NTFS file permissions.

- The top level of a mixed security-style volume can have either UNIX or NTFS effective security and might or might not contain NTFS SACLs.
- Because Storage-Level Access Guard security can be configured on a mixed security-style volume or qtree even if the effective security style of the volume root or qtree is UNIX, the output for a volume or qtree path where Storage-Level Access Guard is configured might display both regular file and folder NFSv4 SACLs and Storage-Level Access Guard NTFS SACLs.
- If the path that is entered in the command is to data with NTFS effective security, the output also displays information about Dynamic Access Control ACEs if Dynamic Access Control is configured for the given file or directory path.
- When displaying security information about files and folders with NTFS effective security, UNIX-related output fields contain display-only UNIX file permission information.

  NTFS security-style files and folders use only NTFS file permissions and Windows users and groups when determining file access rights.
- ACL output is displayed only for files and folders with NTFS or NFSv4 security.

  This field is empty for files and folders using UNIX security that have only mode bit permissions applied (no NFSv4 ACLs).
- The owner and group output fields in the ACL output apply only in the case of NTFS security descriptors.

Step

1. Display file and directory audit policy settings with the desired level of detail:

If you want to display information…	Enter the following command…
In summary form	`vserver security file-directory show -vserver vserver_name -path path`
As a detailed list	`vserver security file-directory show -vserver vserver_name -path path -expand-mask true`

Examples

The following example displays the audit policy information for the path `/corp` in SVM vs1. The path has NTFS effective security. The NTFS security descriptor contains both a SUCCESS and a SUCCESS/FAIL SACL entry.

```
cluster::> vserver security file-directory show -vserver vs1 -path /corp
                Vserver: vs1
              File Path: /corp
      File Inode Number: 357
         Security Style: ntfs
        Effective Style: ntfs
         DOS Attributes: 10
 DOS Attributes in Text: ----D---
Expanded Dos Attributes: -
           Unix User Id: 0
          Unix Group Id: 0
         Unix Mode Bits: 777
 Unix Mode Bits in Text: rwxrwxrwx
                   ACLs: NTFS Security Descriptor
                         Control:0x8014
                         Owner:DOMAIN\Administrator
                         Group:BUILTIN\Administrators
                         SACL - ACEs
                           ALL-DOMAIN\Administrator-0x100081-OI|CI|SA|FA
                           SUCCESSFUL-DOMAIN\user1-0x100116-OI|CI|SA
                         DACL - ACEs
                           ALLOW-BUILTIN\Administrators-0x1f01ff-OI|CI
                           ALLOW-BUILTIN\Users-0x1f01ff-OI|CI
                           ALLOW-CREATOR OWNER-0x1f01ff-OI|CI
                           ALLOW-NT AUTHORITY\SYSTEM-0x1f01ff-OI|CI
```

The following example displays the audit policy information for the path `/datavol1` in SVM vs1. The path contains both regular file and folder SACLs and Storage-Level Access Guard SACLs.

```
cluster::> vserver security file-directory show -vserver vs1 -path
/datavol1

                Vserver: vs1
              File Path: /datavol1

                         DACL - ACEs
                           ALLOW-EXAMPLE\Domain Admins-0x1f01ff-OI|CI
                           ALLOW-EXAMPLE\marketing-0x1200a9-OI|CI

                         Storage-Level Access Guard security
                         SACL (Applies to Directories):
                           AUDIT-EXAMPLE\Domain Users-0x120089-FA
                           AUDIT-EXAMPLE\engineering-0x1f01ff-SA
                         DACL (Applies to Directories):
                           ALLOW-EXAMPLE\Domain Users-0x120089
                           ALLOW-EXAMPLE\engineering-0x1f01ff
                           ALLOW-NT AUTHORITY\SYSTEM-0x1f01ff
                         SACL (Applies to Files):
                           AUDIT-EXAMPLE\Domain Users-0x120089-FA
                           AUDIT-EXAMPLE\engineering-0x1f01ff-SA
                         DACL (Applies to Files):
                           ALLOW-EXAMPLE\Domain Users-0x120089
                           ALLOW-EXAMPLE\engineering-0x1f01ff
                           ALLOW-NT AUTHORITY\SYSTEM-0x1f01ff
```

Use wildcard characters to display information about ONTAP file security and audit policies

You can use the wildcard character (*) to display information about file security and audit policies of all files and directories under a given path or a root volume.

The wildcard character (*) can be used as the last subcomponent of a given directory path below which you want to display information of all files and directories.

If you want to display information of a particular file or directory named as "*", then you need to provide the complete path inside double quotes (" ").

Example

The following command with the wildcard character displays the information about all files and directories below the path `/1/` of SVM vs1:

```
cluster::> vserver security file-directory show -vserver vs1 –path /1/*

                    Vserver: vs1
                  File Path: /1/1
             Security Style: mixed
            Effective Style: ntfs
             DOS Attributes: 10
     DOS Attributes in Text: ----D---
    Expanded Dos Attributes: -
               Unix User Id: 0
              Unix Group Id: 0
             Unix Mode Bits: 777
     Unix Mode Bits in Text: rwxrwxrwx
                       ACLs: NTFS Security Descriptor
                             Control:0x8514
                             Owner:BUILTIN\Administrators
                             Group:BUILTIN\Administrators
                             DACL - ACEs
                             ALLOW-Everyone-0x1f01ff-OI|CI (Inherited)
                    Vserver: vs1
                  File Path: /1/1/abc
             Security Style: mixed
            Effective Style: ntfs
             DOS Attributes: 10
     DOS Attributes in Text: ----D---
    Expanded Dos Attributes: -
               Unix User Id: 0
              Unix Group Id: 0
             Unix Mode Bits: 777
     Unix Mode Bits in Text: rwxrwxrwx
                       ACLs: NTFS Security Descriptor
                             Control:0x8404
                             Owner:BUILTIN\Administrators
                             Group:BUILTIN\Administrators
                             DACL - ACEs
                             ALLOW-Everyone-0x1f01ff-OI|CI (Inherited)
```

The following command displays the information of a file named as "*" under the path `/vol1/a` of SVM vs1. The path is enclosed within double quotes (" ").

```
cluster::> vserver security file-directory show -vserver vs1 -path
"/vol1/a/*"

                 Vserver: vs1
               File Path: "/vol1/a/*"
          Security Style: mixed
         Effective Style: unix
          DOS Attributes: 10
  DOS Attributes in Text: ----D---
Expanded Dos Attributes: -
            Unix User Id: 1002
           Unix Group Id: 65533
          Unix Mode Bits: 755
  Unix Mode Bits in Text: rwxr-xr-x
                    ACLs: NFSV4 Security Descriptor
                          Control:0x8014
                          SACL - ACEs
                            AUDIT-EVERYONE@-0x1f01bf-FI|DI|SA|FA
                          DACL - ACEs
                            ALLOW-EVERYONE@-0x1f00a9-FI|DI
                            ALLOW-OWNER@-0x1f01ff-FI|DI
                            ALLOW-GROUP@-0x1200a9-IG
```

CLI change events that can be audited

Learn about ONTAP CLI change events that can be audited

ONTAP can audit certain CLI change events, including certain SMB-share events, certain audit policy events, certain local security group events, local user group events, and authorization policy events. Understanding which change events can be audited is helpful when interpreting results from the event logs.

You can manage storage virtual machine (SVM) auditing CLI change events by manually rotating the audit logs, enabling or disabling auditing, displaying information about auditing change events, modifying auditing change events, and deleting auditing change events.

As an administrator, if you execute any command to change configuration related to the SMB-share, local user-group, local security-group, authorization-policy, and audit-policy events, a record generates and the corresponding event gets audited:

Auditing Category	Events	Event IDs	Run this command…

Mhost Auditing	policy-change	[4719] Audit configuration changed	`vserver audit disable|enable|modify`
	file-share	[5142] Network share was added	`vserver cifs share create`
		[5143] Network share was modified	`vserver cifs share modify` `vserver cifs share create|modify|delete` `vserver cifs share add|remove`
		[5144] Network share deleted	`vserver cifs share delete`

Auditing

	Rename	`and-groups local-user rename`
security-group	[4731] Local Security Group created	`vserver cifs users-and-groups local-group create` `vserver services name-service unix-group create`
	[4734] Local Security Group deleted	`vserver cifs users-and-groups local-group delete` `vserver services name-service unix-group delete`
	[4735] Local Security Group Modified	`vserver cifs users-and-groups local-group rename|modify` `vserver services name-service unix-group modify`
	[4732] User added to Local Group	`vserver cifs users-and-groups local-group add-members` `vserver services name-service unix-group adduser`
	[4733] User Removed from Local Group	`vserver cifs users-and-groups local-group remove-members` `vserver services name-service unix-group deluser`
authorization-policy-change	[4704] User Rights Assigned	`vserver cifs users-and-groups privilege add-privilege`
	[4705] User Rights Removed	`vserver cifs users-and-groups privilege remove-privilege|reset-privilege`

Manage file-share ONTAP events

When a file-share event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated. The file-share events are generated when the SMB network share is modified using `vserver cifs share` related commands.

The file-share events with the event-ids 5142, 5143, and 5144 are generated when a SMB network share is added, modified, or deleted for the SVM. The SMB network share configuration is modified using the `cifs share access control create|modify|delete` commands.

The following example displays a file-share event with the ID 5143 is generated, when a share object called 'audit_dest' is created:

```
netapp-clus1::*> cifs share create -share-name audit_dest -path
/audit_dest
- System
  - Provider
   [ Name]  NetApp-Security-Auditing
   [ Guid]  {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
   EventID 5142
   EventName Share Object Added
   ...
   ...
  ShareName audit_dest
  SharePath /audit_dest
  ShareProperties oplocks;browsable;changenotify;show-previous-versions;
  SD O:BAG:S-1-5-21-2447422786-1297661003-4197201688-513D:(A;;FA;;;WD)
```

Manage audit-policy-change ONTAP events

When an audit-policy-change event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated. The audit-policy-change events are generated when an audit policy is modified using `vserver audit` related commands.

The audit-policy-change event with the event-id 4719 is generated whenever an audit policy is disabled, enabled, or modified and helps to identify when a user attempts to disable auditing to cover the tracks. It is configured by default and requires diagnostic privilege to disable.

The following example displays an audit-policy change event with the ID 4719 generated, when an audit is disabled:

```
netapp-clus1::*> vserver audit disable -vserver vserver_1
- System
  - Provider
   [ Name]  NetApp-Security-Auditing
   [ Guid]  {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
   EventID 4719
   EventName Audit Disabled
   ...
   ...
  SubjectUserName admin
  SubjectUserSid 65533-1001
  SubjectDomainName ~
  SubjectIP console
  SubjectPort
```

Manage user-account ONTAP events

When a user-account event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated.

The user-account events with event-ids 4720, 4722, 4724, 4725, 4726, 4738, and 4781 are generated when a local SMB or NFS user is created or deleted from the system, local user account is enabled, disabled or modified, and local SMB user password is reset or changed. The user-account events are generated when a user account is modified using `vserver cifs users-and-groups <local user>` and `vserver services name-service <unix user>` commands.

The following example displays a user account event with the ID 4720 generated, when a local SMB user is created:

```
netapp-clus1::*> vserver cifs users-and-groups local-user create -user
-name testuser -is-account-disabled false -vserver vserver_1
Enter the password:
Confirm the password:

- System
  - Provider
   [ Name]  NetApp-Security-Auditing
   [ Guid]  {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
   EventID 4720
   EventName Local Cifs User Created
   ...
   ...
  TargetUserName testuser
  TargetDomainName NETAPP-CLUS1
  TargetSid S-1-5-21-2447422786-1297661003-4197201688-1003
  TargetType CIFS
  DisplayName testuser
  PasswordLastSet 1472662216
  AccountExpires NO
  PrimaryGroupId 513
  UserAccountControl %%0200
  SidHistory ~
  PrivilegeList ~
```

The following example displays a user account event with the ID 4781 generated, when the local SMB user created in the preceding example is renamed:

```
 netapp-clus1::*> vserver cifs users-and-groups local-user rename -user
-name testuser -new-user-name testuser1
- System
  - Provider
   [ Name]  NetApp-Security-Auditing
   [ Guid]  {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
   EventID 4781
   EventName Local Cifs User Renamed
   ...
   ...
  OldTargetUserName testuser
  NewTargetUserName testuser1
  TargetDomainName NETAPP-CLUS1
  TargetSid S-1-5-21-2447422786-1297661003-4197201688-1000
  TargetType CIFS
  SidHistory ~
  PrivilegeList ~
```

Manage security-group ONTAP events

When a security-group event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated.

The security-group events with event-ids 4731, 4732, 4733, 4734, and 4735 are generated when a local SMB or NFS group is created or deleted from the system, and local user is added or removed from the group. The security-group-events are generated when a user account is modified using `vserver cifs users-and-groups <local-group>` and `vserver services name-service <unix-group>` commands.

The following example displays a security group event with the ID 4731 generated, when a local UNIX security group is created:

```
netapp-clus1::*> vserver services name-service unix-group create -name
testunixgroup -id 20
- System
  - Provider
   [ Name]  NetApp-Security-Auditing
   [ Guid]  {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
   EventID 4731
   EventName Local Unix Security Group Created
   ...
   ...
  SubjectUserName admin
  SubjectUserSid 65533-1001
  SubjectDomainName ~
  SubjectIP console
  SubjectPort
  TargetUserName testunixgroup
  TargetDomainName
  TargetGid 20
  TargetType NFS
  PrivilegeList ~
  GidHistory ~
```

Manage authorization-policy-change ONTAP events

When authorization-policy-change event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated.

The authorization-policy-change events with the event-ids 4704 and 4705 are generated whenever the authorization rights are granted or revoked for an SMB user and SMB group. The authorization-policy-change events are generated when the authorization rights are assigned or revoked using `vserver cifs users-and-groups privilege` related commands.

The following example displays an authorization policy event with the ID 4704 generated, when the authorization rights for a SMB user group are assigned:

```
netapp-clus1::*> vserver cifs users-and-groups privilege add-privilege
-user-or-group-name testcifslocalgroup -privileges *
- System
  - Provider
   [ Name]  NetApp-Security-Auditing
   [ Guid]  {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
   EventID 4704
   EventName User Right Assigned
   ...
   ...
  TargetUserOrGroupName testcifslocalgroup
  TargetUserOrGroupDomainName NETAPP-CLUS1
  TargetUserOrGroupSid S-1-5-21-2447422786-1297661003-4197201688-1004;
  PrivilegeList
SeTcbPrivilege;SeBackupPrivilege;SeRestorePrivilege;SeTakeOwnershipPrivile
ge;SeSecurityPrivilege;SeChangeNotifyPrivilege;
  TargetType CIFS
```

Manage auditing configurations

Manually rotate the audit event logs to view specific ONTAP SVM event logs

Before you can view the audit event logs, the logs must be converted to user-readable formats. If you want to view the event logs for a specific storage virtual machine (SVM) before ONTAP automatically rotates the log, you can manually rotate the audit event logs on an SVM.

Step

1. Rotate the audit event logs by using the `vserver audit rotate-log` command.

   ```
   vserver audit rotate-log -vserver vs1
   ```

   The audit event log is saved in the SVM audit event log directory with the format specified by the auditing configuration (`XML` or `EVTX`), and can be viewed by using the appropriate application.

Enable or disable auditing on ONTAP SVMs

You can enable or disable auditing on storage virtual machines (SVMs). You might want to temporarily stop file and directory auditing by disabling auditing. You can enable auditing at any time (if an auditing configuration exists).

Before you begin

Before you can enable auditing on the SVM, the SVM's auditing configuration must already exist.

Create the auditing configuration

About this task

Disabling auditing does not delete the auditing configuration.

Steps

1. Perform the appropriate command:

If you want auditing to be…	Enter the command…
Enabled	`vserver audit enable -vserver vserver_name`
Disabled	`vserver audit disable -vserver vserver_name`

2. Verify that auditing is in the desired state:

   `vserver audit show -vserver vserver_name`

Examples

The following example enables auditing for SVM vs1:

```
cluster1::> vserver audit enable -vserver vs1

cluster1::> vserver audit show -vserver vs1

                             Vserver: vs1
                      Auditing state: true
                Log Destination Path: /audit_log
       Categories of Events to Audit: file-ops, cifs-logon-logoff
                          Log Format: evtx
                 Log File Size Limit: 100MB
        Log Rotation Schedule: Month: -
  Log Rotation Schedule: Day of Week: -
          Log Rotation Schedule: Day: -
         Log Rotation Schedule: Hour: -
       Log Rotation Schedule: Minute: -
                  Rotation Schedules: -
            Log Files Rotation Limit: 10
```

The following example disables auditing for SVM vs1:

```
cluster1::> vserver audit disable -vserver vs1

                            Vserver: vs1
                     Auditing state: false
               Log Destination Path: /audit_log
      Categories of Events to Audit: file-ops, cifs-logon-logoff
                         Log Format: evtx
                Log File Size Limit: 100MB
       Log Rotation Schedule: Month: -
 Log Rotation Schedule: Day of Week: -
         Log Rotation Schedule: Day: -
        Log Rotation Schedule: Hour: -
      Log Rotation Schedule: Minute: -
                 Rotation Schedules: -
           Log Files Rotation Limit: 10
```

Display information about ONTAP auditing configurations

You can display information about auditing configurations. The information can help you determine whether the configuration is what you want in place for each SVM. The displayed information also enables you to verify whether an auditing configuration is enabled.

About this task

You can display detailed information about auditing configurations on all SVMs or you can customize what information is displayed in the output by specifying optional parameters. If you do not specify any of the optional parameters, the following is displayed:

- SVM name to which the auditing configuration applies
- The audit state, which can be `true` or `false`

  If the audit state is `true`, auditing is enabled. If the audit state is `false`, auditing is disabled.
- The categories of events to audit
- The audit log format
- The target directory where the auditing subsystem stores consolidated and converted audit logs

Step

1. Display information about the auditing configuration by using the `vserver audit show` command.

   Learn more about `vserver audit show` in the ONTAP command reference.

Examples

The following example displays a summary of the auditing configuration for all SVMs:

```
cluster1::> vserver audit show

 Vserver     State  Event Types Log Format Target Directory
 ----------- ------ ----------- ---------- --------------------
 vs1         false  file-ops    evtx       /audit_log
```

The following example displays, in list form, all auditing configuration information for all SVMs:

```
cluster1::> vserver audit show -instance

                             Vserver: vs1
                      Auditing state: true
                Log Destination Path: /audit_log
       Categories of Events to Audit: file-ops
                          Log Format: evtx
                 Log File Size Limit: 100MB
        Log Rotation Schedule: Month: -
  Log Rotation Schedule: Day of Week: -
          Log Rotation Schedule: Day: -
         Log Rotation Schedule: Hour: -
       Log Rotation Schedule: Minute: -
                  Rotation Schedules: -
            Log Files Rotation Limit: 0
```

ONTAP commands for modifying auditing configurations

If you want to change an auditing setting, you can modify the current configuration at any time, including modifying the log path destination and log format, modifying the categories of events to audit, how to automatically save log files, and specify the maximum number of log files to save.

If you want to…	Use this command…
Modify the log destination path	`vserver audit modify` with the `-destination` parameter
Modify the category of events to audit	`vserver audit modify` with the `-events` parameter ⓘ To audit central access policy staging events, the Dynamic Access Control (DAC) SMB server option must be enabled on the storage virtual machine (SVM).

Modify the log format	`vserver audit modify` with the `-format` parameter
Enabling automatic saves based on internal log file size	`vserver audit modify` with the `-rotate-size` parameter
Enabling automatic saves based on a time interval	`vserver audit modify` with the `-rotate -schedule-month`, `-rotate-schedule -dayofweek`, `-rotate-schedule-day`, `-rotate -schedule-hour`, and `-rotate-schedule -minute` parameters
Specifying the maximum number of saved log files	`vserver audit modify` with the `-rotate-limit` parameter

Delete an auditing configuration on an ONTAP SVM

In you no longer want to audit file and directory events on the storage virtual machine (SVM) and do not want to maintain an auditing configuration on the SVM, you can delete the auditing configuration.

Steps

1. Disable the auditing configuration:

   `vserver audit disable -vserver vserver_name`

   `vserver audit disable -vserver vs1`

2. Delete the auditing configuration:

   `vserver audit delete -vserver vserver_name`

   `vserver audit delete -vserver vs1`

Understand the implications of reverting an audited ONTAP cluster

If you plan to revert the cluster, you should be aware of the revert process ONTAP follows when there are auditing-enabled storage virtual machines (SVMs) in the cluster. You must take certain actions before reverting.

Reverting to a version of ONTAP that does not support the auditing of SMB logon and logoff events and central access policy staging events

Support for auditing of SMB logon and logoff events and for central access policy staging events starts with clustered Data ONTAP 8.3. If you are reverting to a version of ONTAP that does not support these event types and you have auditing configurations that monitor these event types, you must change the auditing configuration for those audit-enabled SVMs before reverting. You must modify the configuration so that only file-op events are audited.

Troubleshoot ONTAP auditing and staging volume space issues

Issues can arise when there is insufficient space on either the staging volumes or on the volume containing the audit event logs. If there is insufficient space, new audit records cannot be created, which prevents clients from accessing data, and access requests fail. You should know how to troubleshoot and resolve these volume space issues.

Troubleshoot space issues related to the event log volumes

If volumes containing event log files run out of space, auditing cannot convert log records into log files. This results in client access failures. You must know how to troubleshoot space issues related to event log volumes.

- Storage virtual machine (SVM) and cluster administrators can determine whether there is insufficient volume space by displaying information about volume and aggregate usage and configuration.
- If there is insufficient space in the volumes containing event logs, SVM and cluster administrators can resolve the space issues by either removing some of the event log files or by increasing the size of the volume.

  > If the aggregate that contains the event log volume is full, then the size of the aggregate must be increased before you can increase the size of the volume. Only a cluster administrator can increase the size of an aggregate.

- The destination path for the event log files can be changed to a directory on another volume by modifying the auditing configuration.

  > Data access is denied in the following cases:
  >
  > - The destination directory is deleted.
  > - The file limit on a volume, which hosts the destination directory, reaches to its maximum level.

Learn more about:

- How to view information about volumes and increasing volume size.
- How to view information about aggregates and managing aggregates.

Troubleshoot space issues related to the staging volumes

If any of the volumes containing staging files for your storage virtual machine (SVM) runs out of space, auditing cannot write log records into staging files. This results in client access failures. To troubleshoot this issue, you need to determine whether any of the staging volumes used in the SVM are full by displaying information about volume usage.

If the volume containing the consolidated event log files has sufficient space but there are still client access failures due to insufficient space, then the staging volumes might be out of space. The SVM administrator must contact you to determine whether the staging volumes that contain staging files for the SVM have insufficient space. The auditing subsystem generates an EMS event if auditing events cannot be generated due to insufficient space in a staging volume. The following message is displayed: `No space left on device`. Only you can view information about staging volumes; SVM administrators cannot.

All staging volume names begin with `MDV_aud_` followed by the UUID of the aggregate containing that staging volume. The following example shows four system volumes on the admin SVM, which were automatically created when a file services auditing configuration was created for a data SVM in the cluster:

```
cluster1::> volume show -vserver cluster1
Vserver   Volume       Aggregate    State      Type       Size  Available
Used%
--------- ------------ ------------ ---------- ---- ---------- ----------
-----
cluster1  MDV_aud_1d0131843d4811e296fc123478563412
                       aggr0        online     RW          5GB     4.75GB
5%
cluster1  MDV_aud_8be27f813d7311e296fc123478563412
                       root_vs0     online     RW          5GB     4.75GB
5%
cluster1  MDV_aud_9dc4ad503d7311e296fc123478563412
                       aggr1        online     RW          5GB     4.75GB
5%
cluster1  MDV_aud_a4b887ac3d7311e296fc123478563412
                       aggr2        online     RW          5GB     4.75GB
5%
4 entries were displayed.
```

If there is insufficient space in the staging volumes, you can resolve the space issues by increasing the size of the volume.

> If the aggregate that contains the staging volume is full, then the size of the aggregate must be increased before you can increase the size of the volume. Only you can increase the size of an aggregate; SVM administrators cannot.

If one or more aggregates have an available space of less than 2GB (in ONTAP 9.14.1 and earlier) or 5GB (beginning with ONTAP 9.15.1), the SVM audit creation fails. When the SVM audit creation fails, the staging volumes that were created are deleted.

Use FPolicy for file monitoring and management on SVMs

Understand FPolicy

Learn about two part ONTAP FPolicy solutions

FPolicy is a file access notification framework that is used to monitor and manage file access events on storage virtual machines (SVMs) through partner solutions. Partner solutions help you address various use cases such as data governance and compliance, ransomware protection, and data mobility.

Partner solutions include both NetApp-supported third-party solutions and NetApp products Workload Security and Cloud Data Sense.

There are two parts to an FPolicy solution. The ONTAP FPolicy framework manages activities on the cluster and sends notifications to Partner Application (aka External FPolicy Servers). External FPolicy servers process notifications sent by ONTAP FPolicy to fulfill customer use cases.

The ONTAP framework creates and maintains the FPolicy configuration, monitors file events, and sends notifications to external FPolicy servers. ONTAP FPolicy provides the infrastructure that allows communication between external FPolicy servers and storage virtual machine (SVM) nodes.

The FPolicy framework connects to external FPolicy servers and sends notifications for certain file system events to the FPolicy servers when these events occur as a result of client access. The external FPolicy servers process the notifications and send responses back to the node. What happens as a result of the notification processing depends on the application and whether the communication between the node and the external servers is asynchronous or synchronous.

ONTAP FPolicy synchronous and asynchronous notifications

FPolicy sends notifications to external FPolicy servers via the FPolicy interface. The notifications are sent either in synchronous or asynchronous mode. The notification mode determines what ONTAP does after sending notifications to FPolicy servers.

- **Asynchronous notifications**

  With asynchronous notifications, the node does not wait for a response from the FPolicy server, which enhances overall throughput of the system. This type of notification is suitable for applications where the FPolicy server does not require that any action be taken as a result of notification evaluation. For example, asynchronous notifications are used when the storage virtual machine (SVM) administrator wants to monitor and audit file access activity.

  If an FPolicy server operating in asynchronous mode experiences a network outage, FPolicy notifications generated during the outage are stored on the storage node. When the FPolicy server comes back online, it is alerted of the stored notifications and can fetch them from the storage node. The length of time the notifications can be stored during an outage is configurable up to 10 minutes.

  Beginning with ONTAP 9.14.1, FPolicy allows you to set up a persistent store to capture file access events for asynchronous non-mandatory policies in the SVM. Persistent stores can help decouple client I/O processing from FPolicy notification processing to reduce client latency. Synchronous (mandatory or non-mandatory) and asynchronous mandatory configurations are not supported.

- **Synchronous notifications**

  When configured to run in synchronous mode, the FPolicy server must acknowledge every notification before the client operation is allowed to continue. This type of notification is used when an action is required based on the results of notification evaluation. For example, synchronous notifications are used when the SVM administrator wants to either allow or deny requests based on criteria specified on the external FPolicy server.

Synchronous and asynchronous applications

There are many possible uses for FPolicy applications, both asynchronous and synchronous.

Asynchronous applications are ones where the external FPolicy server does not alter access to files or directories or modify data on the storage virtual machine (SVM). For example:

- File access and audit logging

* Storage resource management

Synchronous applications are ones where data access is altered or data is modified by the external FPolicy server. For example:

* Quota management
* File access blocking
* File archiving and hierarchical storage management
* Encryption and decryption services
* Compression and decompression services

ONTAP FPolicy persistent stores

Persistent stores can help decouple client I/O processing from FPolicy notification processing to reduce client latency. Beginning with ONTAP 9.14.1, you can set up an FPolicy persistent store to capture file access events for asynchronous non-mandatory policies in the SVM. Synchronous (either mandatory or non-mandatory) and asynchronous mandatory configurations are not supported.

This feature is only available in FPolicy external mode. The partner application you use needs to support this feature. You should work with your partner to ensure this FPolicy configuration is supported.

Beginning with ONTAP 9.15.1, FPolicy persistent store configuration is simplified. The `persistent-store create` command automates volume creation for the SVM and configures the volume with persistent store best practices.

For more information on persistent store best practices, refer to Requirements, considerations, and best practices for configuring FPolicy.

For information on adding persistent stores, refer to Create persistent stores.

ONTAP FPolicy configuration types

There are two basic FPolicy configuration types. One configuration uses external FPolicy servers to process and act upon notifications. The other configuration does not use external FPolicy servers; instead, it uses the ONTAP internal, native FPolicy server for simple file blocking based on extensions.

* **External FPolicy server configuration**

  The notification is sent to the FPolicy server, which screens the request and applies rules to determine whether the node should allow the requested file operation. For synchronous policies, the FPolicy server then sends a response to the node to either allow or block the requested file operation.

* **Native FPolicy server configuration**

  The notification is screened internally. The request is allowed or denied based on file extension settings configured in the FPolicy scope.

  Note: File extension requests that are denied are not logged.

When to create a native FPolicy configuration

Native FPolicy configurations use the ONTAP internal FPolicy engine to monitor and block file operations based on the file's extension. This solution does not require external FPolicy servers (FPolicy servers). Using a native file blocking configuration is appropriate when this simple solution is all that is needed.

Native file blocking enables you to monitor any file operations that match configured operation and filtering events and then deny access to files with particular extensions. This is the default configuration.

This configuration provides a means to block file access based only on the file's extension. For example, to block files that contain `mp3` extensions, you configure a policy to provide notifications for certain operations with target file extensions of `mp3`. The policy is configured to deny `mp3` file requests for operations that generate notifications.

The following applies to native FPolicy configurations:

- The same set of filters and protocols that are supported by FPolicy server-based file screening are also supported for native file blocking.
- Native file blocking and FPolicy server-based file screening applications can be configured at the same time.

  To do so, you can configure two separate FPolicy policies for the storage virtual machine (SVM), with one configured for native file blocking and one configured for FPolicy server-based file screening.

- The native file blocking feature only screens files based on the extensions and not on the content of the file.
- In the case of symbolic links, native file blocking uses the file extension of the root file.

Learn more about FPolicy: Native File Blocking.

When to create a configuration that uses external FPolicy servers

FPolicy configurations that use external FPolicy servers to process and manage notifications provide robust solutions for use cases where more than simple file blocking based on file extension is needed.

You should create a configuration that uses external FPolicy servers when you want to do such things as monitor and record file access events, provide quota services, perform file blocking based on criteria other than simple file extensions, provide data migration services using hierarchical storage management applications, or provide a fine-grained set of policies that monitor only a subset of data in the storage virtual machine (SVM).

Cluster component roles in ONTAP FPolicy implementation

The cluster, the contained storage virtual machines (SVMs), and data LIFs all play a role in an FPolicy implementation.

- **cluster**

  The cluster contains the FPolicy management framework and maintains and manages information about all FPolicy configurations in the cluster.

- **SVM**

  An FPolicy configuration is defined at the SVM level. The scope of the configuration is the SVM, and it only operates on SVM resources. One SVM configuration cannot monitor and send notifications for file access requests that are made for data residing on another SVM.

FPolicy configurations can be defined on the admin SVM. After configurations are defined on the admin SVM, they can be seen and used in all SVMs.

- **data LIFs**

  Connections to the FPolicy servers are made through data LIFs belonging to the SVM with the FPolicy configuration. The data LIFs used for these connections can fail over in the same manner as data LIFs used for normal client access.

How ONTAP FPolicy works with external FPolicy servers

After FPolicy is configured and enabled on the storage virtual machine (SVM), FPolicy runs on every node on which the SVM participates. FPolicy is responsible for establishing and maintaining connections with external FPolicy servers (FPolicy servers), for notification processing, and for managing notification messages to and from FPolicy servers.

Additionally, as part of connection management, FPolicy has the following responsibilities:

- Ensures that file notification flows through the correct LIF to the FPolicy server.
- Ensures that when multiple FPolicy servers are associated with a policy, load balancing is done when sending notifications to the FPolicy servers.
- Attempts to reestablish the connection when a connection to an FPolicy server is broken.
- Sends the notifications to FPolicy servers over an authenticated session.
- Manages the passthrough-read data connection established by the FPolicy server for servicing client requests when passthrough-read is enabled.

How control channels are used for FPolicy communication

FPolicy initiates a control channel connection to an external FPolicy server from the data LIFs of each node participating on a storage virtual machine (SVM). FPolicy uses control channels for transmitting file notifications; therefore, an FPolicy server might see multiple control channel connections based on SVM topology.

How privileged data access channels are used for synchronous communication

With synchronous use cases, the FPolicy server accesses data residing on the storage virtual machine (SVM) through a privileged data access path. Access through the privileged path exposes the complete file system to the FPolicy server. It can access data files to collect information, to scan files, read files, or write into files.

Because the external FPolicy server can access the entire file system from the root of the SVM through the privileged data channel, the privileged data channel connection must be secure.

How FPolicy connection credentials are used with privileged data access channels

The FPolicy server makes privileged data access connections to cluster nodes by using a specific Windows user credential that is saved with the FPolicy configuration. SMB is the only supported protocol for making a privileged data access channel connection.

If the FPolicy server requires privileged data access, the following conditions must be met:

* A SMB license must be enabled on the cluster.
* The FPolicy server must run under the credentials configured in the FPolicy configuration.

When making a data channel connection, FPolicy uses the credential for the specified Windows user name. Data access is made over the admin share ONTAP_ADMIN$.

What granting super user credentials for privileged data access means

ONTAP uses the combination of the IP address and the user credential configured in the FPolicy configuration to grant super user credentials to the FPolicy server.

Super user status grants the following privileges when the FPolicy server accesses data:

* Avoid permission checks

  The user avoids checks on files and directory access.

* Special locking privileges

  ONTAP allows read, write, or modify access to any file regardless of existing locks. If the FPolicy server takes byte range locks on the file, it results in immediate removal of existing locks on the file.

* Bypass any FPolicy checks

  Access does not generate any FPolicy notifications.

How FPolicy manages policy processing

There might be multiple FPolicy policies assigned to your storage virtual machine (SVM); each with a different priority. To create an appropriate FPolicy configuration on the SVM, it is important to understand how FPolicy manages policy processing.

Each file access request is initially evaluated to determine which policies are monitoring this event. If it is a monitored event, information about the monitored event along with interested policies is passed to FPolicy where it is evaluated. Each policy is evaluated in order of the assigned priority.

You should consider the following recommendations when configuring policies:

* When you want a policy to always be evaluated before other policies, configure that policy with a higher priority.
* If the success of requested file access operation on a monitored event is a prerequisite for a file request that is evaluated against another policy, give the policy that controls the success or failure of the first file operation a higher priority.

  For example, if one policy manages FPolicy file archiving and restore functionality and a second policy manages file access operations on the online file, the policy that manages file restoration must have a higher priority so that the file is restored before the operation managed by the second policy can be allowed.

* If you want all policies that might apply to a file access operation to be evaluated, give synchronous policies a lower priority.

You can reorder policy priorities for existing policies by modifying the policy sequence number. However, to have FPolicy evaluate policies based on the modified priority order, you must disable and reenable the policy with the modified sequence number.

Node-to-external ONTAP FPolicy server communication process

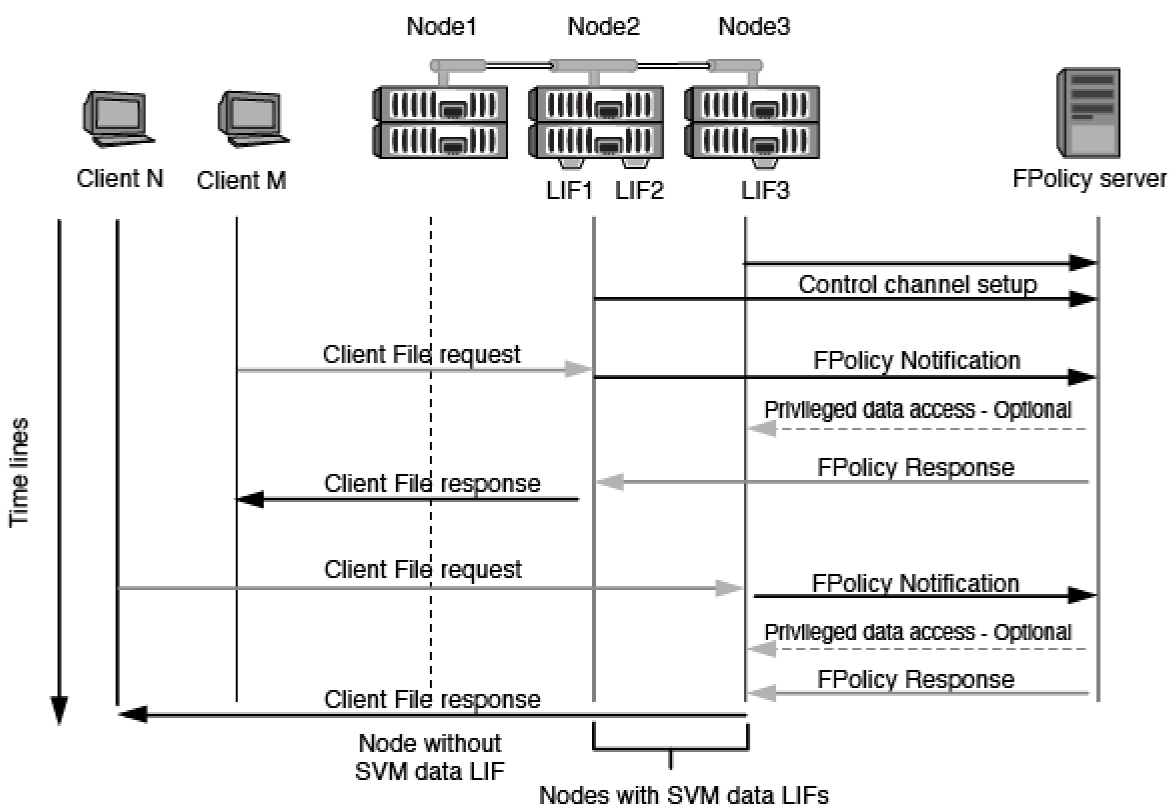
To properly plan your FPolicy configuration, you should understand what the node-to-external FPolicy server communication process is.

Every node that participates on each storage virtual machine (SVM) initiates a connection to an external FPolicy server (FPolicy server) using TCP/IP. Connections to the FPolicy servers are set up using node data LIFs; therefore, a participating node can set up a connection only if the node has an operational data LIF for the SVM.

Each FPolicy process on participating nodes attempts to establish a connection with the FPolicy server when the policy is enabled. It uses the IP address and port of the FPolicy external engine specified in the policy configuration.

The connection establishes a control channel from each of the nodes participating on each SVM to the FPolicy server through the data LIF. In addition, if IPv4 and IPv6 data LIF addresses are present on the same participating node, FPolicy attempts to establish connections for both IPv4 and IPv6. Therefore, in a scenario where the SVM extends over multiple nodes or if both IPv4 and IPv6 addresses are present, the FPolicy server must be ready for multiple control channel setup requests from the cluster after the FPolicy policy is enabled on the SVM.

For example, if a cluster has three nodes—Node1, Node2, and Node3—and SVM data LIFs are spread across only Node2 and Node3, control channels are initiated only from Node2 and Node3, irrespective of the distribution of data volumes. Say that Node2 has two data LIFs—LIF1 and LIF2—that belong to the SVM and that the initial connection is from LIF1. If LIF1 fails, FPolicy attempts to establish a control channel from LIF2.



How FPolicy manages external communication during LIF migration or failover

Data LIFs can be migrated to data ports in the same node or to data ports on a remote node.

When a data LIF fails over or is migrated, a new control channel connection is made to the FPolicy server. FPolicy can then retry SMB and NFS client requests that timed out, with the result that new notifications are sent to the external FPolicy servers. The node rejects FPolicy server responses to original, timed-out SMB and NFS requests.

How FPolicy manages external communication during node failover

If the cluster node that hosts the data ports used for FPolicy communication fails, ONTAP breaks the connection between the FPolicy server and the node.

The impact of cluster failover to the FPolicy server can be mitigated by configuring the failover-policy to migrate the data port used in FPolicy communication to another active node. After the migration is complete, a new connection is established using the new data port.

If the failover-policy is not configured to migrate the data port, the FPolicy server must wait for the failed node to come up. After the node is up, a new connection is initiated from that node with a new Session ID.

> ⓘ The FPolicy server detects broken connections with the keep-alive protocol message. The timeout for purging the session ID is determined when configuring FPolicy. The default keep-alive timeout is two minutes.

Learn about ONTAP FPolicy services across SVM namespaces

ONTAP provides a unified storage virtual machine (SVM) namespace. Volumes across the cluster are joined together by junctions to provide a single, logical file system. The FPolicy server is aware of the namespace topology and provides FPolicy services across the namespace.

The namespace is specific to and contained within the SVM; therefore, you can see the namespace only from the SVM context. Namespaces have the following characteristics:

- A single namespace exists in each SVM, with the root of the namespace being the root volume, represented in the namespace as slash (/).
- All other volumes have junction points below the root (/).
- Volume junctions are transparent to clients.
- A single NFS export can provide access to the complete namespace; otherwise, export policies can export specific volumes.
- SMB shares can be created on the volume or on qtrees within the volume, or on any directory within the namespace.
- The namespace architecture is flexible.

  Examples of typical namespace architectures are as follows:

  - A namespace with a single branch off of the root
  - A namespace with multiple branches off of the root
  - A namespace with multiple unbranched volumes off of the root

How ONTAP FPolicy passthrough-read enhances usability for hierarchical storage management

Passthrough-read enables the FPolicy server (functioning as the hierarchical storage management (HSM) server) to provide read access to offline files without having to recall the file from the secondary storage system to the primary storage system.

When an FPolicy server is configured to provide HSM to files residing on a SMB server, policy-based file migration occurs where the files are stored offline on secondary storage and only a stub file remains on primary storage. Even though a stub file appears as a normal file to clients, it is actually a sparse file that is the same size of the original file. The sparse file has the SMB offline bit set and points to the actual file that has been migrated to secondary storage.

Typically when a read request for an offline file is received, the requested content must be recalled back to primary storage and then accessed through primary storage. The need to recall data back to primary storage has several undesirable effects. Among the undesirable effects is the increased latency to client requests caused by the need to recall the content before responding to the request and the increased space consumption needed for recalled files on the primary storage.

FPolicy passthrough-read allows the HSM server (the FPolicy server) to provide read access to migrated, offline files without having to recall the file from the secondary storage system to the primary storage system. Instead of recalling the files back to primary storage, read requests can be serviced directly from secondary storage.

> Copy Offload (ODX) is not supported with FPolicy passthrough-read operation.

Passthrough-read enhances usability by providing the following benefits:

- Read requests can be serviced even if the primary storage does not have sufficient space to recall requested data back to primary storage.
- Better capacity and performance management when a surge of data recall might occur, such as if a script or a backup solution needs to access many offline files.
- Read requests for offline files in snapshots can be serviced.

  Because snapshots are read-only, the FPolicy server cannot restore the original file if the stub file is located in a snapshot. Using passthrough-read eliminates this problem.

- Policies can be set up that control when read requests are serviced through access to the file on secondary storage and when the offline file should be recalled to primary storage.

  For example, a policy can be created on the HSM server that specifies the number of times the offline file can be accessed in a specified period of time before the file is migrated back to primary storage. This type of policy avoids recalling files that are rarely accessed.

How read requests are managed when FPolicy passthrough-read is enabled

You should understand how read requests are managed when FPolicy passthrough-read is enabled so that you can optimally configure connectivity between the storage virtual machine (SVM) and the FPolicy servers.

When FPolicy passthrough-read is enabled and the SVM receives a request for an offline file, FPolicy sends a notification to the FPolicy server (HSM server) through the standard connection channel.

After receiving the notification, the FPolicy server reads the data from the file path sent in the notification and sends the requested data to the SVM through the passthrough-read privileged data connection that is established between the SVM and the FPolicy server.

After the data is sent, the FPolicy server then responds to the read request as an ALLOW or DENY. Based on whether the read request is allowed or denied, ONTAP either sends the requested information or sends an error message to the client.

Plan the FPolicy configuration

Requirements, considerations, and best practices for configuring ONTAP FPolicy

Before you create and configure FPolicy configurations on your storage virtual machines (SVMs), you need to be aware of certain requirements, considerations, and best practices for configuring FPolicy.

FPolicy features are configured either through the command line interface (CLI) or through REST APIs.

Requirements for setting up FPolicy

Before you configure and enable FPolicy on your storage virtual machine (SVM), you need to be aware of certain requirements.

- All nodes in the cluster must be running a version of ONTAP that supports FPolicy.
- If you are not using the ONTAP native FPolicy engine, you must have external FPolicy servers (FPolicy servers) installed.
- The FPolicy servers must be installed on a server accessible from the data LIFs of the SVM where FPolicy policies are enabled.

> Beginning with ONTAP 9.8, ONTAP provides a client LIF service for outbound FPolicy connections with the addition of the `data-fpolicy-client` service. Learn more about LIFs and service policies.

- The IP address of the FPolicy server must be configured as a primary or secondary server in the FPolicy policy external engine configuration.
- If the FPolicy servers access data over a privileged data channel, the following additional requirements must be met:
  - SMB must be licensed on the cluster.

    Privileged data access is accomplished using SMB connections.
  - A user credential must be configured for accessing files over the privileged data channel.
  - The FPolicy server must run under the credentials configured in the FPolicy configuration.
  - All data LIFs used to communicate with the FPolicy servers must be configured to have `cifs` as one of the allowed protocols.

    This includes the LIFs used for passthrough-read connections.

Best practices and recommendations when setting up FPolicy

When setting up FPolicy on storage virtual machines (SVMs), get familiar with the general configuration best practices and recommendations to ensure that your FPolicy configuration provides robust monitoring performance and results that meet your requirements.

For specific guidelines related to performance, sizing, and configuration, work with your FPolicy partner application.

Persistent stores

Beginning with ONTAP 9.14.1, FPolicy allows you to set up a persistent store to capture file access events for asynchronous non-mandatory policies in the SVM. Persistent stores can help decouple client I/O processing from FPolicy notification processing to reduce client latency. Synchronous (either mandatory or non-mandatory) and asynchronous mandatory configurations are not supported.

- Before using the persistent store functionality, ensure your partner applications support this configuration.
- You need one persistent store for each SVM where FPolicy is enabled.
  - Only one persistent store can be set up on each SVM. This single persistent store needs to be used for all FPolicy configurations on that SVM, even if the policies are from different partners.
- ONTAP 9.15.1 or later:
  - The persistent store, its volume, and its volume configuration is handled automatically when you create the persistent store.
- ONTAP 9.14.1:
  - The persistent store, its volume, and its volume configuration is handled manually.
- Create the persistent store volume on the node with LIFs that expect maximum traffic to be monitored by FPolicy.
  - ONTAP 9.15.1 or later: Volumes are automatically created and configured during persistent store creation.
  - ONTAP 9.14.1: Cluster administrators need to create and configure a volume for the persistent store on each SVM where FPolicy is enabled.
- If the notifications accumulated in the persistent store exceed the size of the volume provisioned, FPolicy starts dropping the incoming notification with appropriate EMS messages.
  - ONTAP 9.15.1 or later: In addition to the `size` parameter, the `autosize-mode` parameter can help the volume grow or shrink in response to the amount of used space.
  - ONTAP 9.14.1: The `size` parameter is configured during volume creation to provide a maximum limit.
- Set the snapshot policy to `none` for the persistent store volume instead of `default`. This is to ensure that there is no accidental restore of the snapshot leading to loss of current events and to prevent possible duplicate event processing.
  - ONTAP 9.15.1 or later: The `snapshot-policy` parameter is automatically configured to none during persistent store creation.
  - ONTAP 9.14.1: The `snapshot-policy` parameter is configured to `none` during volume creation.
- Make the persistent store volume inaccessible for external user protocol access (CIFS/NFS) to avoid accidental corruption or deletion of the persisted event records.
  - ONTAP 9.15.1 or later: ONTAP automatically blocks the volume from external user protocol access (CIFS/NFS) during persistent store creation.
  - ONTAP 9.14.1: After enabling FPolicy, unmount the volume in ONTAP to remove the junction path. This makes it inaccessible for external user protocol access (CIFS/NFS).

For more information, refer to FPolicy persistent stores and Create persistent stores.

Persistent store failover and giveback

The persistent store remains as it was when the last event was received, when there is an unexpected reboot, or FPolicy is disabled and enabled again. After a takeover operation, new events are stored and processed by the partner node. After a giveback operation, the persistent store resumes processing any unprocessed events that might remain from when the node takeover occurred. Live events would be given priority over unprocessed events.

If the persistent store volume moves from one node to another in the same SVM, the notifications that are yet to be processed also move to the new node. You need to re-run the `fpolicy persistent-store create` command on either node after the volume is moved to ensure the pending notifications are delivered to the external server.

Learn more about `fpolicy persistent-store create` in the ONTAP command reference.

Policy configuration

Configuration of the FPolicy external engine, events, and scope for SVMs can improve your overall experience and security.

- Configuration of the FPolicy external engine for SVMs:
  - Providing additional security comes with a performance cost. Enabling Secure Sockets Layer (SSL) communication has a performance effect on accessing shares.
  - The FPolicy external engine should be configured with more than one FPolicy server to provide resiliency and high availability of FPolicy server notification processing.
- Configuration of FPolicy events for SVMs:

  Monitoring file operations influences your overall experience. For example, filtering unwanted file operations on the storage side improves your experience. NetApp recommends setting up the following configuration:

  - Monitoring the minimum types of file operations and enabling the maximum number of filters without breaking the use case.
  - Using filters for getattr, read, write, open, and close operations. The SMB and NFS home directory environments have a high percentage of these operations.
- Configuration of FPolicy scope for SVMs:

  Restrict the scope of the policies to the relevant storage objects, such as shares, volumes, and exports, instead of enabling them across the entire SVM. NetApp recommends checking the directory extensions. If the `is-file-extension-check-on-directories-enabled` parameter is set to `true`, directory objects are subjected to the same extension checks as regular files.

Network configuration

Network connectivity between the FPolicy server and the controller should be of low latency. NetApp recommends separating FPolicy traffic from client traffic by using a private network.

In addition, you should place external FPolicy servers (FPolicy servers) in close proximity to the cluster with high-bandwidth connectivity to provide minimal latency and high-bandwidth connectivity.

> ⓘ For a scenario in which the LIF for FPolicy traffic is configured on a different port to the LIF for client traffic, the FPolicy LIF might fail over to the other node because of a port failure. As a result, the FPolicy server becomes unreachable from the node which causes the FPolicy notifications for file operations on the node to fail. To avoid this issue, verify that the FPolicy server can be reached through at least one LIF on the node to process FPolicy requests for the file operations performed on that node.

Hardware configuration

You can have the FPolicy server on either a physical server or a virtual server. If the FPolicy server is in a virtual environment, you should allocate dedicated resources (CPU, network, and memory) to the virtual server.

The cluster node-to-FPolicy server ratio should be optimized to ensure that FPolicy servers are not overloaded, which can introduce latencies when the SVM responds to client requests. The optimal ratio depends on the partner application for which the FPolicy server is being used. NetApp recommends working with partners to determine the appropriate value.

Multiple-policy configuration

The FPolicy policy for native blocking has the highest priority, irrespective of the sequence number, and decision-altering policies have a higher priority than others. Policy priority depends on the use case. NetApp recommends working with partners to determine the appropriate priority.

Size considerations

FPolicy performs in-line monitoring of SMB and NFS operations, sends notifications to the external server, and waits for a response, depending on the mode of external engine communication (synchronous or asynchronous). This process affects the performance of SMB and NFS access and CPU resources.

To mitigate any issues, NetApp recommends working with partners to assess and size the environment before enabling FPolicy. Performance is affected by several factors including the number of users, workload characteristics, such as operations per user and data size, network latency, and failure or server slowness.

Monitor performance

FPolicy is a notification-based system. Notifications are sent to an external server for processing and to generate a response back to ONTAP. This round-trip process increases latency for client access.

Monitoring the performance counters on the FPolicy server and in ONTAP gives you the capability to identify bottlenecks in the solution and to tune the parameters as necessary for an optimal solution. For example, an increase in FPolicy latency has a cascading effect on SMB and NFS access latency. Therefore, you should monitor both workload (SMB and NFS) and FPolicy latency. In addition, you can use quality-of-service policies in ONTAP to set up a workload for each volume or SVM that is enabled for FPolicy.

NetApp recommends running the `statistics show –object workload` command to display workload statistics. In addition, you should monitor the following parameters:

- Average, read, and write latencies
- Total number of operations
- Read and write counters

You can monitor the performance of FPolicy subsystems by using the following FPolicy counters.

You must be in diagnostic mode to collect statistics related to FPolicy.

Steps

1. Collect FPolicy counters:
   a. `statistics start -object fpolicy -instance <instance_name> -sample-id <ID>`
   b. `statistics start -object fpolicy_policy -instance <instance_name> -sample-id <ID>`
2. Display FPolicy counters:
   a. `statistics show -object fpolicy -instance <instance_name> -sample-id <ID>`
   b. `statistics show -object fpolicy_server -instance <instance_name> -sample-id <ID>`

   The `fpolicy` and `fpolicy_server` counters give you information on several performance parameters which are described in the following table.

Counters	Description
fpolicy counters	
aborted_requests	Number of screen requests for which processing is aborted on the SVM
event_count	List of events resulting in notification
max_request_latency	Maximum screen requests latency
outstanding_requests	Total number of screen requests in process
processed_requests	Total number of screen requests that went through fpolicy processing on the SVM
request_latency_hist	Histogram of latency for screen requests
requests_dispatched_rate	Number of screen requests dispatched per second
requests_received_rate	Number of screen requests received per second
fpolicy_server counters	
max_request_latency	Maximum latency for a screen request
outstanding_requests	Total number of screen requests waiting for response
request_latency	Average latency for screen request
request_latency_hist	Histogram of latency for screen requests
request_sent_rate	Number of screen requests sent to FPolicy server per second
response_received_rate	Number of screen responses received from FPolicy server per second

Learn more about `statistics start` and `statistics show` in the ONTAP command reference.

Manage FPolicy workflow and dependency on other technologies

NetApp recommends disabling an FPolicy policy before making any configuration changes. For example, if you want to add or modify an IP address in the external engine configured for the enabled policy, first disable the policy.

If you configure FPolicy to monitor NetApp FlexCache volumes, NetApp recommends that you not configure FPolicy to monitor read and getattr file operations. Monitoring these operations in ONTAP requires the retrieval of inode-to-path (I2P) data. Because I2P data cannot be retrieved from FlexCache volumes, it must be retrieved from the origin volume. Therefore, monitoring these operations eliminates the performance benefits that FlexCache can provide.

When both FPolicy and an off-box antivirus solution are deployed, the antivirus solution receives notifications first. FPolicy processing starts only after antivirus scanning is complete. It is important that you size antivirus solutions correctly because a slow antivirus scanner can affect overall performance.

Passthrough-read upgrade and revert considerations

There are certain upgrade and revert considerations that you must know about before upgrading to an ONTAP release that supports passthrough-read or before reverting to a release that does not support passthrough-read.

Upgrading

After all nodes are upgraded to a version of ONTAP that supports FPolicy passthrough-read, the cluster is capable of using the passthrough-read functionality; however, passthrough-read is disabled by default on existing FPolicy configurations. To use passthrough-read on existing FPolicy configurations, you must disable the FPolicy policy and modify the configuration, and then reenable the configuration.

Reverting

Before reverting to a version of ONTAP that does not support FPolicy passthrough-read, you must meet the following conditions:

- Disable all the policies using passthrough-read, and then modify the affected configurations so that they do not use passthrough-read.
- Disable FPolicy functionality on the cluster by disabling every FPolicy policy on the cluster.

Before reverting to a version of ONTAP that does not support persistent stores, ensure that none of the FPolicy policies have a configured persistent store. If a persistent store is configured, the revert will fail.

Set up ONTAP FPolicy configurations

Before FPolicy can monitor file access, an FPolicy configuration must be created and enabled on the storage virtual machine (SVM) for which FPolicy services are required.

The steps for setting up and enabling an FPolicy configuration on the SVM are as follows:

1. Create an FPolicy external engine.

The FPolicy external engine identifies the external FPolicy servers (FPolicy servers) that are associated with a specific FPolicy configuration. If the internal “native” FPolicy engine is used to create a native file-blocking configuration, you do not need to create an FPolicy external engine.

Beginning with ONTAP 9.15.1, you can use the `protobuf` engine format. When set to `protobuf`, the notification messages are encoded in binary form using Google Protobuf. Before setting the engine format to `protobuf`, ensure that the FPolicy server also supports `protobuf` deserialization. For more information, see Plan the FPolicy external engine configuration

2. Create an FPolicy event.

   An FPolicy event describes what the FPolicy policy should monitor. Events consist of the protocols and file operations to monitor, and can contain a list of filters. Events use filters to narrow the list of monitored events for which the FPolicy external engine must send notifications. Events also specify whether the policy monitors volume operations.

3. Create an FPolicy persistent store (optional).

   Beginning with ONTAP 9.14.1, FPolicy allows you to set up persistent stores to capture file access events for asynchronous non-mandatory policies in the SVM. Synchronous (either mandatory or non-mandatory) and asynchronous mandatory configurations are not supported.

   Persistent stores can help decouple client I/O processing from FPolicy notification processing to reduce client latency.

   Beginning with ONTAP 9.15.1, FPolicy persistent store configuration is simplified. The `persistent-store-create` command automates volume creation for the SVM and configures the volume for the persistent store.

4. Create an FPolicy policy.

   The FPolicy policy is responsible for associating, with the appropriate scope, the set of events that need to be monitored and for which of the monitored events notifications must be sent to the designated FPolicy server (or to the native engine if no FPolicy servers are configured). The policy also defines whether the FPolicy server is allowed privileged access to the data for which it receives notifications. An FPolicy server needs privileged access if the server needs to access the data. Typical use cases where privileged access is needed include file blocking, quota management, and hierarchical storage management. The policy is where you specify whether the configuration for this policy uses an FPolicy server or the internal “native” FPolicy server.

   A policy specifies whether screening is mandatory. If screening is mandatory and all FPolicy servers are down or no response is received from the FPolicy servers within a defined timeout period, then file access is denied.

   A policy’s boundaries are the SVM. A policy cannot apply to more than one SVM. However, a specific SVM can have multiple FPolicy policies, each with the same or different combination of scope, event, and external server configurations.

5. Configure the policy scope.

   The FPolicy scope determines which volumes, shares, or export-policies the policy acts on or excludes from monitoring. A scope also determines which file extensions should be included or excluded from FPolicy monitoring.

   > Exclude lists take precedence over include lists.

6. Enable the FPolicy policy.

   When the policy is enabled, the control channels and, optionally, the privileged data channels are connected. The FPolicy process on the nodes on which the SVM participates begin monitoring file and folder access and, for events that match configured criteria, sends notifications to the FPolicy servers (or to the native engine if no FPolicy servers are configured).

   > If the policy uses native file blocking, an external engine is not configured or associated with the policy.

Plan the FPolicy external engine configuration

Plan ONTAP FPolicy external engine configurations

Before you configure the FPolicy external engine, you must understand what it means to create an external engine and which configuration parameters are available. This information helps you to determine which values to set for each parameter.

Information that is defined when creating the FPolicy external engine

The external engine configuration defines the information that FPolicy needs to make and manage connections to the external FPolicy servers, including the following:

- SVM name
- Engine name
- The IP addresses of the primary and secondary FPolicy servers and the TCP port number to use when making the connection to the FPolicy servers
- Whether the engine type is asynchronous or synchronous
- Whether the engine format is `xml` or `protobuf`

  Beginning with ONTAP 9.15.1, you can use the `protobuf` engine format. When set to `protobuf`, the notification messages are encoded in binary form using Google Protobuf. Before setting the engine format to `protobuf`, ensure that the FPolicy server also supports `protobuf` deserialization.

  Since the protobuf format is supported beginning with ONTAP 9.15.1, you must consider external engine format before reverting to an earlier release of ONTAP. If you revert to an earlier release than ONTAP 9.15.1, work with your FPolicy partner to either:

  - Change each engine format from `protobuf` to `xml`
  - Delete the engines with an engine format of `protobuf`
- How to authenticate the connection between the node and the FPolicy server

  If you choose to configure mutual SSL authentication, then you must also configure parameters that provide SSL certificate information.
- How to manage the connection using various advanced privilege settings

  This includes parameters that define such things as timeout values, retry values, keep-alive values, maximum request values, sent and receive buffer size values, and session timeout values.

The `vserver fpolicy policy external-engine create` command is used to create an FPolicy external engine.

What the basic external engine parameters are

You can use the following table of basic FPolicy configuration parameters to help you plan your configuration:

Type of information	Option
SVM Specifies the SVM name that you want to associate with this external engine. Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.	`-vserver vserver_name`
Engine name Specifies the name to assign to the external engine configuration. You must specify the external engine name later when you create the FPolicy policy. This associates the external engine with the policy. The name can be up to 256 characters long. The name should be up to 200 characters long if configuring the external engine name in a MetroCluster or SVM disaster recovery configuration. The name can contain any combination of the following ASCII-range characters: • `a` through `z` • `A` through `Z` • `0` through `9` • "_", "-", and "."	`-engine-name engine_name`

Primary FPolicy servers Specifies the primary FPolicy servers to which the node sends notifications for a given FPolicy policy. The value is specified as a comma-delimited list of IP addresses. If more than one primary server IP address is specified, every node on which the SVM participates creates a control connection to every specified primary FPolicy server at the time the policy is enabled. If you configure multiple primary FPolicy servers, notifications are sent to the FPolicy servers in a round-robin fashion. If the external engine is used in a MetroCluster or SVM disaster recovery configuration, you should specify the IP addresses of the FPolicy servers at the source site as primary servers. The IP addresses of the FPolicy servers at the destination site should be specified as secondary servers.	`-primary-servers IP_address,...`
Port number Specifies the port number of the FPolicy service.	`-port integer`
Secondary FPolicy servers Specifies the secondary FPolicy servers to which to send file access events for a given FPolicy policy. The value is specified as a comma-delimited list of IP addresses. Secondary servers are used only when none of the primary servers are reachable. Connections to secondary servers are established when the policy is enabled, but notifications are sent to secondary servers only if none of the primary servers are reachable. If you configure multiple secondary servers, notifications are sent to the FPolicy servers in a round-robin fashion.	`-secondary-servers IP_address,...`
External engine type Specifies whether the external engine operates in synchronous or asynchronous mode. By default, FPolicy operates in synchronous mode. When set to `synchronous`, file request processing sends a notification to the FPolicy server, but then does not continue until after receiving a response from the FPolicy server. At that point, request flow either continues or processing results in denial, depending on whether the response from the FPolicy server permits the requested action. When set to `asynchronous`, file request processing sends a notification to the FPolicy server, and then continues.	`-extern-engine-type external_engine_type` The value for this parameter can be one of the following: • `synchronous` • `asynchronous`

External engine format Specify whether the external engine format is xml or protobuf. Beginning with ONTAP 9.15.1, you can use the protobuf engine format. When set to protobuf, the notification messages are encoded in binary form using Google Protobuf. Before setting the engine format to protobuf, ensure that the FPolicy server also supports protobuf deserialization.	`- extern-engine-format` {`protobuf` or `xml`}
SSL option for communication with FPolicy server Specifies the SSL option for communication with the FPolicy server. This is a required parameter. You can choose one of the options based on the following information: • When set to `no-auth`, no authentication takes place. The communication link is established over TCP. • When set to `server-auth`, the SVM authenticates the FPolicy server using SSL server authentication. • When set to `mutual-auth`, mutual authentication takes place between the SVM and the FPolicy server; the SVM authenticates the FPolicy server, and the FPolicy server authenticates the SVM. If you choose to configure mutual SSL authentication, then you must also configure the `-certificate-common-name`, `-certificate -serial`, and `-certifcate-ca` parameters.	`-ssl-option` {`no-auth` |`server-auth`|`mutual-auth`}
Certificate FQDN or custom common name Specifies the certificate name used if SSL authentication between the SVM and the FPolicy server is configured. You can specify the certificate name as an FQDN or as a custom common name. If you specify `mutual-auth` for the `-ssl-option` parameter, you must specify a value for the `-certificate-common-name` parameter.	`-certificate-common -name` `text`
Certificate serial number Specifies the serial number of the certificate used for authentication if SSL authentication between the SVM and the FPolicy server is configured. If you specify `mutual-auth` for the `-ssl-option` parameter, you must specify a value for the `-certificate-serial` parameter.	`-certificate-serial` `text`

Certificate authority Specifies the CA name of the certificate used for authentication if SSL authentication between the SVM and the FPolicy server is configured. If you specify `mutual-auth` for the `-ssl-option` parameter, you must specify a value for the `-certificate-ca` parameter.	`-certificate-ca` text

What the advanced external engine options are

You can use the following table of advanced FPolicy configuration parameters as you plan whether to customize your configuration with advanced parameters. You use these parameters to modify communication behavior between the cluster nodes and the FPolicy servers:

Type of information	Option
Timeout for canceling a request Specifies the time interval in hours (`h`), minutes (`m`), or seconds (`s`) that the node waits for a response from the FPolicy server. If the timeout interval passes, the node sends a cancel request to the FPolicy server. The node then sends the notification to an alternate FPolicy server. This timeout helps in handling an FPolicy server that is not responding, which can improve SMB/NFS client response. Also, canceling requests after a timeout period can help in releasing system resources because the notification request is moved from a down/bad FPolicy server to an alternate FPolicy server. The range for this value is `0` through `100`. If the value is set to `0`, the option is disabled and cancel request messages are not sent to the FPolicy server. The default is `20s`.	`-reqs-cancel-timeout integer`[h|m|s]
Timeout for aborting a request Specifies the timeout in hours (`h`), minutes (`m`), or seconds (`s`) for aborting a request. The range for this value is `0` through `200`.	`-reqs-abort-timeout `` `integer`[h|m|s]
Interval for sending status requests Specifies the interval in hours (`h`), minutes (`m`), or seconds (`s`) after which a status request is sent to the FPolicy server. The range for this value is `0` through `50`. If the value is set to `0`, the option is disabled and status request messages are not sent to the FPolicy server. The default is `10s`.	`-status-req-interval integer`[h|m|s]

Maximum outstanding requests on the FPolicy server Specifies the maximum number of outstanding requests that can be queued on the FPolicy server. The range for this value is `1` through `10000`. The default is `500`.	`-max-server-reqs` `integer`
Timeout for disconnecting a nonresponsive FPolicy server Specifies the time interval in hours (`h`), minutes (`m`), or seconds (`s`) after which the connection to the FPolicy server is terminated. The connection is terminated after the timeout period only if the FPolicy server's queue contains the maximum allowed requests and no response is received within the timeout period. The maximum allowed number of requests is either `50` (the default) or the number specified by the `max-server-reqs-` parameter. The range for this value is `1` through `100`. The default is `60s`.	`-server-progress -timeout` `integer`[h|m|s]
Interval for sending keep-alive messages to the FPolicy server Specifies the time interval in hours (`h`), minutes (`m`), or seconds (`s`) at which keep-alive messages are sent to the FPolicy server. Keep-alive messages detect half-open connections. The range for this value is `10` through `600`. If the value is set to `0`, the option is disabled and keep-alive messages are prevented from being sent to the FPolicy servers. The default is `120s`.	`-keep-alive-interval-` `integer`[h|m|s]
Maximum reconnect attempts Specifies the maximum number of times the SVM attempts to reconnect to the FPolicy server after the connection has been broken. The range for this value is `0` through `20`. The default is `5`.	`-max-connection-retries` `integer`
Receive buffer size Specifies the receive buffer size of the connected socket for the FPolicy server. The default value is set to 256 kilobytes (Kb). When the value is set to 0, the size of the receive buffer is set to a value defined by the system. For example, if the default receive buffer size of the socket is 65536 bytes, by setting the tunable value to 0, the socket buffer size is set to 65536 bytes. You can use any non-default value to set the size (in bytes) of the receive buffer.	`-recv-buffer-size` `integer`

Send buffer size Specifies the send buffer size of the connected socket for the FPolicy server. The default value is set to 256 kilobytes (Kb). When the value is set to 0, the size of the send buffer is set to a value defined by the system. For example, if the default send buffer size of the socket is set to 65536 bytes, by setting the tunable value to 0, the socket buffer size is set to 65536 bytes. You can use any non-default value to set the size (in bytes) of the send buffer.	`-send-buffer-size integer`
Timeout for purging a session ID during reconnection Specifies the interval in hours (`h`), minutes (`m`), or seconds (`s`) after which a new session ID is sent to the FPolicy server during reconnection attempts. If the connection between the storage controller and the FPolicy server is terminated and reconnection is made within the `-session-timeout` interval, the old session ID is sent to FPolicy server so that it can send responses for old notifications. The default value is set to 10 seconds.	`-session-timeout [integerh][integerm][integers]`

Additional information about configuring ONTAP FPolicy external engines to use SSL authenticated connections

You need to know some additional information if you want to configure the FPolicy external engine to use SSL when connecting to FPolicy servers.

SSL server authentication

If you choose to configure the FPolicy external engine for SSL server authentication, before creating the external engine, you must install the public certificate of the certificate authority (CA) that signed the FPolicy server certificate.

Mutual authentication

If you configure FPolicy external engines to use SSL mutual authentication when connecting storage virtual machine (SVM) data LIFs to external FPolicy servers, before creating the external engine, you must install the public certificate of the CA that signed the FPolicy server certificate along with the public certificate and key file for authentication of the SVM. Do not delete this certificate while any FPolicy policies are using the installed certificate.

If the certificate is deleted while FPolicy is using it for mutual authentication when connecting to an external FPolicy server, you cannot reenable a disabled FPolicy policy that uses that certificate. The FPolicy policy cannot be reenabled in this situation even if a new certificate with the same settings is created and installed on the SVM.

If the certificate has been deleted, you need to install a new certificate, create new FPolicy external engines that use the new certificate, and associate the new external engines with the FPolicy policy that you want to reenable by modifying the FPolicy policy.

Install certificates for SSL

The public certificate of the CA that is used to sign the FPolicy server certificate is installed by using the `security certificate install` command with the `-type` parameter set to `client-ca`. The private key and public certificate required for authentication of the SVM is installed by using the `security certificate install` command with the `-type` parameter set to `server`.

Related information

- security certificate install

ONTAP FPolicy certificates do not replicate in SVM disaster recovery relationships with a non-ID-preserve configuration

Security certificates used for SSL authentication when making connections to FPolicy servers do not replicate to SVM disaster recovery destinations with non-ID-preserve configurations. Although the FPolicy external-engine configuration on the SVM is replicated, security certificates are not replicated. You must manually install the security certificates on the destination.

When you set up the SVM disaster recovery relationship, the value you select for the `-identity-preserve` option of the `snapmirror create` command determines the configuration details that are replicated in the destination SVM.

If you set the `-identity-preserve` option to `true` (ID-preserve), all of the FPolicy configuration details are replicated, including the security certificate information. You must install the security certificates on the destination only if you set the option to `false` (non-ID-preserve).

Related information

- snapmirror create

Restrictions for cluster-scoped ONTAP FPolicy external engines with MetroCluster and SVM disaster recovery configurations

You can create a cluster-scoped FPolicy external engine by assigning the cluster storage virtual machine (SVM) to the external engine. However, when creating a cluster-scoped external engine in a MetroCluster or SVM disaster recovery configuration, there are certain restrictions when choosing the authentication method that the SVM uses for external communication with the FPolicy server.

There are three authentication options that you can choose when creating external FPolicy servers: no authentication, SSL server authentication, and SSL mutual authentication. Although there are no restrictions when choosing the authentication option if the external FPolicy server is assigned to a data SVM, there are restrictions when creating a cluster-scoped FPolicy external engine:

Configuration	Permitted?
MetroCluster or SVM disaster recovery and a cluster-scoped FPolicy external engine with no authentication (SSL is not configured)	Yes
MetroCluster or SVM disaster recovery and a cluster-scoped FPolicy external engine with SSL server or SSL mutual authentication	No

- If a cluster-scoped FPolicy external engine with SSL authentication exists and you want to create a MetroCluster or SVM disaster recovery configuration, you must modify this external engine to use no authentication or remove the external engine before you can create the MetroCluster or SVM disaster recovery configuration.
- If the MetroCluster or SVM disaster recovery configuration already exists, ONTAP prevents you from creating a cluster-scoped FPolicy external engine with SSL authentication.

Complete ONTAP FPolicy external engine configuration worksheets

You can use this worksheet to record the values that you need during the FPolicy external engine configuration process. If a parameter value is required, you need to determine what value to use for those parameters before you configure the external engine.

Information for a basic external engine configuration

You should record whether you want to include each parameter setting in the external engine configuration and then record the value for the parameters that you want to include.

Type of information	Required	Include	Your values
Storage virtual machine (SVM) name	Yes	Yes	
Engine name	Yes	Yes	
Primary FPolicy servers	Yes	Yes	
Port number	Yes	Yes	
Secondary FPolicy servers	No		
External engine type	No		
SSL option for communication with external FPolicy server	Yes	Yes	
Certificate FQDN or custom common name	No		
Certificate serial number	No		
Certificate authority	No		

Information for advanced external engine parameters

To configure an external engine with advanced parameters, you must enter the configuration command while in advanced privilege mode.

Type of information	Required	Include	Your values

Timeout for canceling a request	No		
Timeout for aborting a request	No		
Interval for sending status requests	No		
Maximum outstanding requests on the FPolicy server	No		
Timeout for disconnecting a nonresponsive FPolicy server	No		
Interval for sending keep-alive messages to the FPolicy server	No		
Maximum reconnect attempts	No		
Receive buffer size	No		
Send buffer size	No		
Timeout for purging a session ID during reconnection	No		

Plan the FPolicy event configuration

Learn about ONTAP FPolicy event configuration

Before you configure FPolicy events, you must understand what it means to create an FPolicy event. You must determine which protocols you want the event to monitor, which events to monitor, and which event filters to use. This information helps you plan the values that you want to set.

What it means to create an FPolicy event

Creating the FPolicy event means defining information that the FPolicy process needs to determine what file access operations to monitor and for which of the monitored events notifications should be sent to the external FPolicy server. The FPolicy event configuration defines the following configuration information:

- Storage virtual machine (SVM) name
- Event name
- Which protocols to monitor

  FPolicy can monitor SMB, NFSv3, NFSv4, and, beginning with ONTAP 9.15.1, NFSv4.1 file access operations.

- Which file operations to monitor

Not all file operations are valid for each protocol.

- Which file filters to configure

  Only certain combinations of file operations and filters are valid. Each protocol has its own set of supported combinations.

- Whether to monitor volume mount and unmount operations

> There is a dependency with three of the parameters (`-protocol`, `-file-operations`, `-filters`). The following combinations are valid for the three parameters:
>
> - You can specify the `-protocol` and `-file-operations` parameters.
> - You can specify all three of the parameters.
> - You can specify none of the parameters.

What the FPolicy event configuration contains

You can use the following list of available FPolicy event configuration parameters to help you plan your configuration:

Type of information	Option
SVM Specifies the SVM name that you want to associate with this FPolicy event. Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.	`-vserver vserver_name`

Event name Specifies the name to assign to the FPolicy event. When you create the FPolicy policy you associate the FPolicy event with the policy using the event name. The name can be up to 256 characters long. ⓘ The name should be up to 200 characters long if configuring the event in a MetroCluster or SVM disaster recovery configuration. The name can contain any combination of the following ASCII-range characters: • `a` through `z` • `A` through `Z` • `0` through `9` • " _ ", “-”, and “.”	`-event-name` `event_name`
Protocol Specifies which protocol to configure for the FPolicy event. The list for `-protocol` can include one of the following values: • `cifs` • `nfsv3` • `nfsv4` ⓘ If you specify `-protocol`, then you must specify a valid value in the `-file-operations` parameter. As the protocol version changes, the valid values might change. ⓘ Beginning with ONTAP 9.15.1, nfsv4 allows you to capture NFSv4.0 and NFSv4.1 events.	`-protocol` `protocol`

File operations Specifies the list of file operations for the FPolicy event. The event checks the operations specified in this list from all client requests using the protocol specified in the `-protocol` parameter. You can list one or more file operations by using a comma-delimited list. The list for `-file -operations` can include one or more of the following values: • `close` for file close operations • `create` for file create operations • `create-dir` for directory create operations • `delete` for file delete operations • `delete_dir` for directory delete operations • `getattr` for get attribute operations • `link` for link operations • `lookup` for lookup operations • `open` for file open operations • `read` for file read operations • `write` for file write operations • `rename` for file rename operations • `rename_dir` for directory rename operations • `setattr` for set attribute operations • `symlink` for symbolic link operations ⓘ If you specify `-file-operations`, then you must specify a valid protocol in the `-protocol` parameter.	`-file-operations file_operations,…`

Filters Specifies the list of filters for a given file operation for the specified protocol. The values in the `-filters` parameter are used to filter client requests. The list can include one or more of the following: If you specify the `-filters` parameter, then you must also specify valid values for the `-file-operations` and `-protocol` parameters. • `monitor-ads` option to filter the client request for alternate data stream. • `close-with-modification` option to filter the client request for close with modification. • `close-without-modification` option to filter the client request for close without modification. • `first-read` option to filter the client request for first read. • `first-write` option to filter the client request for first write. • `offline-bit` option to filter the client request for offline bit set. Setting this filter results in the FPolicy server receiving notification only when offline files are accessed. • `open-with-delete-intent` option to filter the client request for open with delete intent. Setting this filter results in the FPolicy server receiving notification only when an attempt is made to open a file with the intent to delete it. This is used by file systems when the `FILE_DELETE_ON_CLOSE` flag is specified. • `open-with-write-intent` option to filter client request for open with write intent. Setting this filter results in the FPolicy server receiving notification only when an attempt is made to open a file with the intent to write something in it. • `write-with-size-change` option to filter the client request for write with size change. • `setattr-with-owner-change` option to filter the client setattr requests for changing owner of a file or a directory. • `setattr-with-group-change` option to filter the client setattr requests for changing the group of a file or a directory. • `setattr-with-sacl-change` option to filter the client setattr requests for changing the SACL on a file or a directory. This filter is available only for the SMB and NFSv4 protocols. `setattr-with-dacl-change` option to filter the client setattr requests for changing the DACL on a file or a directory. This filter is available only for the SMB and NFSv4 protocols.	`-filters filter, …`

Is volume operation required Specifies whether monitoring is required for volume mount and unmount operations. The default is `false`.	`-volume-operation` {`true`|`false`} `-filters` `filter`, ...
FPolicy access denied notifications Beginning with ONTAP 9.13.1, users can receive notifications for failed file operations due to lack of permissions. These notifications are valuable for security, ransomware protection, and governance. Notifications will be generated for file operation failed due to lack of permission, which includes: • Failures due to NTFS permissions. • Failures due to Unix mode bits. • Failures due to NFSv4 ACLs.	`-monitor-fileop-failure` {`true`|`false`}

This option is available only for the SMB protocol.

- `exclude-directory` option to filter the client requests for directory operations.

  When this filter is specified, the directory operations are not monitored.

Supported file operation and filter combinations ONTAP FPolicy monitors for SMB

When you configure your FPolicy event, you need to be aware that only certain combinations of file operations and filters are supported for monitoring SMB file access operations.

The list of supported file operation and filter combinations for FPolicy monitoring of SMB file access events is provided in the following table:

Supported file operations	Supported filters
close	monitor-ads, offline-bit, close-with-modification, close-without-modification, close-with-read, exclude-directory
create	monitor-ads, offline-bit
create_dir	Currently no filter is supported for this file operation.
delete	monitor-ads, offline-bit
delete_dir	Currently no filter is supported for this file operation.
getattr	offline-bit, exclude-dir
open	monitor-ads, offline-bit, open-with-delete-intent, open-with-write-intent, exclude-dir
read	monitor-ads, offline-bit, first-read
write	monitor-ads, offline-bit, first-write, write-with-size-change

rename	monitor-ads, offline-bit
rename_dir	Currently no filter is supported for this file operation.
setattr	monitor-ads, offline-bit, setattr_with_owner_change, setattr_with_group_change, setattr_with_mode_change, setattr_with_sacl_change, setattr_with_dacl_change, setattr_with_modify_time_change, setattr_with_access_time_change, setattr_with_creation_time_change, setattr_with_size_change, setattr_with_allocation_size_change, exclude_directory

Beginning with ONTAP 9.13.1, users can receive notifications for failed file operations due to lack of permissions. The list of supported access denied file operation and filter combinations for FPolicy monitoring of SMB file access events is provided in the following table:

Supported access denied file operation	Supported filters
open	NA

Supported file operation and filter combinations that ONTAP FPolicy monitors for NFSv3

When you configure your FPolicy event, you need to be aware that only certain combinations of file operations and filters are supported for monitoring NFSv3 file access operations.

The list of supported file operation and filter combinations for FPolicy monitoring of NFSv3 file access events is provided in the following table:

Supported file operations	Supported filters
create	offline-bit
create_dir	Currently no filter is supported for this file operation.
delete	offline-bit
delete_dir	Currently no filter is supported for this file operation.
link	offline-bit
lookup	offline-bit, exclude-dir
read	offline-bit, first-read
write	offline-bit, first-write, write-with-size-change

rename	offline-bit
rename_dir	Currently no filter is supported for this file operation.
setattr	offline-bit, setattr_with_owner_change, setattr_with_group_change, setattr_with_mode_change, setattr_with_modify_time_change, setattr_with_access_time_change, setattr_with_size_change, exclude_directory
symlink	offline-bit

Beginning with ONTAP 9.13.1, users can receive notifications for failed file operations due to lack of permissions. The list of supported access denied file operation and filter combinations for FPolicy monitoring of NFSv3 file access events is provided in the following table:

Supported access denied file operation	**Supported filters**
access	NA
create	NA
create_dir	NA
delete	NA
delete_dir	NA
link	NA
read	NA
rename	NA
rename_dir	NA
setattr	NA
write	NA

Supported file operation and filter combinations that ONTAP FPolicy monitors for NFSv4

When you configure your FPolicy event, you need to be aware that only certain combinations of file operations and filters are supported for monitoring NFSv4 file access operations.

Beginning with ONTAP 9.15.1, FPolicy supports the NFSv4.1 protocol.

The list of supported file operation and filter combinations for FPolicy monitoring of NFSv4 or NFSv4.1 file access events is provided in the following table:

Supported file operations	Supported filters
close	offline-bit, exclude-directory
create	offline-bit
create_dir	Currently no filter is supported for this file operation.
delete	offline-bit
delete_dir	Currently no filter is supported for this file operation.
getattr	offline-bit, exclude-directory
link	offline-bit
lookup	offline-bit, exclude-directory
open	offline-bit, exclude-directory
read	offline-bit, first-read
write	offline-bit, first-write, write-with-size-change
rename	offline-bit
rename_dir	Currently no filter is supported for this file operation.
setattr	offline-bit, setattr_with_owner_change, setattr_with_group_change, setattr_with_mode_change, setattr_with_sacl_change, setattr_with_dacl_change, setattr_with_modify_time_change, setattr_with_access_time_change, setattr_with_size_change, exclude_directory
symlink	offline-bit

Beginning with ONTAP 9.13.1, users can receive notifications for failed file operations due to lack of permissions. The list of supported access denied file operation and filter combinations for FPolicy monitoring of NFSv4 or NFSv4.1 file access events is provided in the following table:

Supported access denied file operation	Supported filters

access	NA
create	NA
create_dir	NA
delete	NA
delete_dir	NA
link	NA
open	NA
read	NA
rename	NA
rename_dir	NA
setattr	NA
write	NA

Complete ONTAP FPolicy event configuration worksheets

You can use this worksheet to record the values that you need during the FPolicy event configuration process. If a parameter value is required, you need to determine what value to use for those parameters before you configure the FPolicy event.

You should record whether you want to include each parameter setting in the FPolicy event configuration and then record the value for the parameters that you want to include.

Type of information	Required	Include	Your values
Storage virtual machine (SVM) name	Yes	Yes	
Event name	Yes	Yes	
Protocol	No		
File operations	No		
Filters	No		

Volume operation	No		
Access denied events (support beginning with ONTAP 9.13)	No		

Plan the FPolicy policy configuration

Learn about ONTAP FPolicy policy configurations

Before you configure the FPolicy policy, you must understand which parameters are required when creating the policy as well as why you might want to configure certain optional parameters. This information helps you to determine which values to set for each parameter.

When creating an FPolicy policy you associate the policy with the following:

- The storage virtual machine (SVM)
- One or more FPolicy events
- An FPolicy external engine

You can also configure several optional policy settings.

What the FPolicy policy configuration contains

You can use the following list of available FPolicy policy required and optional parameters to help you plan your configuration:

Type of information	Option	Required	Default
SVM name Specifies the name of the SVM on which you want to create an FPolicy policy.	`-vserver vserver_name`	Yes	None

<table>
<tr><td>Policy name

Specifies the name of the FPolicy policy.

The name can be up to 256 characters long.

The name should be up to 200 characters long if configuring the policy in a MetroCluster or SVM disaster recovery configuration.

The name can contain any combination of the following ASCII-range characters:
<code>a</code> through <code>z</code>
<code>A</code> through <code>Z</code>
<code>0</code> through <code>9</code>
“_”, “-”, and “.”</td><td><code>-policy-name policy_name</code></td><td>Yes</td><td>None</td></tr>
<tr><td>Event names

Specifies a comma-delimited list of events to associate with the FPolicy policy.
You can associate more than one event to a policy.
An event is specific to a protocol.
You can use a single policy to monitor file access events for more than one protocol by creating an event for each protocol that you want the policy to monitor, and then associating the events to the policy.
The events must already exist.</td><td><code>-events event_name</code>, …</td><td>Yes</td><td>None</td></tr>
<tr><td>Persistent store

Beginning with ONTAP 9.14.1, this parameter specifies the persistent store to capture file access events for asynchronous non-mandatory policies in the SVM.</td><td><code>-persistent -store persistent_store_name</code></td><td>No</td><td>None</td></tr>
</table>

External engine name Specifies the name of the external engine to associate with the FPolicy policy. • An external engine contains information required by the node to send notifications to an FPolicy server. • You can configure FPolicy to use the ONTAP native external engine for simple file blocking or to use an external engine that is configured to use external FPolicy servers (FPolicy servers) for more sophisticated file blocking and file management. • If you want to use the native external engine, you can either not specify a value for this parameter or you can specify `native` as the value. • If you want to use FPolicy servers, the configuration for the external engine must already exist.	`-engine engine_name`	Yes (unless the policy uses the internal ONTAP native engine)	`native`
Is mandatory screening required Specifies whether mandatory file access screening is required. • The mandatory screening setting determines what action is taken on a file access event in a case when all primary and secondary servers are down or no response is received from the FPolicy servers within a given timeout period. • When set to `true`, file access events are denied. • When set to `false`, file access events are allowed.	`-is-mandatory {true|false}`	No	`true`

Allow privileged access Specifies whether you want the FPolicy server to have privileged access to the monitored files and folders by using a privileged data connection. If configured, FPolicy servers can access files from the root of the SVM containing the monitored data using the privileged data connection. For privileged data access, SMB must be licensed on the cluster and all the data LIFs used to connect to the FPolicy servers must be configured to have `cifs` as one of the allowed protocols. If you want to configure the policy to allow privileged access, you must also specify the user name for the account that you want the FPolicy server to use for privileged access.	`-allow -privileged -access {yes|no}`	No (unless passthrough-read is enabled)	`no`
Privileged user name Specifies the user name of the account the FPolicy servers use for privileged data access. • The value for this parameter should use the “domain\user name” format. • If `-allow-privileged-access` is set to `no`, any value set for this parameter is ignored.	`-privileged -user-name user_name`	No (unless privileged access is enabled)	None

Allow passthrough-read Specifies whether the FPolicy servers can provide passthrough-read services for files that have been archived to secondary storage (offline files) by the FPolicy servers: • Passthrough-read is a way to read data for offline files without restoring the data to the primary storage. Passthrough-read reduces response latencies because there is no need to recall files back to primary storage before responding to the read request. Additionally, passthrough-read optimizes storage efficiency by eliminating the need to consume primary storage space with files that are recalled solely to satisfy read requests. • When enabled, the FPolicy servers provide the data for the file over a separate privileged data channel opened specifically for passthrough-reads. • If you want to configure passthrough-read, the policy must also be configured to allow privileged access.	`-is-passthrough-read-enabled {true|false}`	No	`false`

Requirement for ONTAP FPolicy scope configurations if the FPolicy policy uses the native engine

If you configure the FPolicy policy to use the native engine, there is a specific requirement for how you define the FPolicy scope configured for the policy.

The FPolicy scope defines the boundaries on which the FPolicy policy applies, for example whether the FPolicy applies to specified volumes or shares. There are a number of parameters that further restrict the scope to which the FPolicy policy applies. One of these parameters, `-is-file-extension-check-on-directories-enabled`, specifies whether to check file extensions on directories. The default value is `false`, which means that file extensions on directories are not checked.

When an FPolicy policy that uses the native engine is enabled on a share or volume and the `-is-file-extension-check-on-directories-enabled` parameter is set to `false` for the scope of the policy, directory access is denied. With this configuration, because the file extensions are not checked for directories, any directory operation is denied if it falls under the scope of the policy.

To ensure that directory access succeeds when using the native engine, you must set the `-is-file-extension-check-on-directories-enabled parameter` to `true` when creating the scope.

With this parameter set to `true`, extension checks happen for directory operations and the decision whether to allow or deny access is taken based on the extensions included or excluded in the FPolicy scope configuration.

Complete ONTAP FPolicy policy worksheets

You can use this worksheet to record the values that you need during the FPolicy policy configuration process. You should record whether you want to include each parameter setting in the FPolicy policy configuration and then record the value for the parameters that you want to include.

Type of information	Include	Your values
Storage virtual machine (SVM) name	Yes	
Policy name	Yes	
Event names	Yes	
Persistent store		
External engine name		
Is mandatory screening required?		
Allow privileged access		
Privileged user name		
Is passthrough-read enabled?		

Plan the FPolicy scope configuration

Learn about ONTAP FPolicy scope configurations

Before you configure the FPolicy scope, you must understand what it means to create a scope. You must understand what the scope configuration contains. You also need to understand what the scope rules of precedence are. This information can help you plan the values that you want to set.

What it means to create an FPolicy scope

Creating the FPolicy scope means defining the boundaries on which the FPolicy policy applies. The storage virtual machine (SVM) is the basic boundary. When you create a scope for an FPolicy policy, you must define the FPolicy policy to which it will apply, and you must designate to which SVM you want to apply the scope.

There are a number of parameters that further restrict the scope within the specified SVM. You can restrict the scope by specifying what to include in the scope or by specifying what to exclude from the scope. After you apply a scope to an enabled policy, policy event checks get applied to the scope defined by this command.

Notifications are generated for file access events where matches are found in the “include” options.

Notifications are not generated for file access events where matches are found in the "exclude" options.

The FPolicy scope configuration defines the following configuration information:

- SVM name
- Policy name
- The shares to include or exclude from what gets monitored
- The export policies to include or exclude from what gets monitored
- The volumes to include or exclude from what gets monitored
- The file extensions to include or exclude from what gets monitored
- Whether to do file extension checks on directory objects

> There are special considerations for the scope for a cluster FPolicy policy. The cluster FPolicy policy is a policy that the cluster administrator creates for the admin SVM. If the cluster administrator also creates the scope for that cluster FPolicy policy, the SVM administrator cannot create a scope for that same policy. However, if the cluster administrator does not create a scope for the cluster FPolicy policy, then any SVM administrator can create the scope for that cluster policy. If the SVM administrator creates a scope for that cluster FPolicy policy, the cluster administrator cannot subsequently create a cluster scope for that same cluster policy. This is because the cluster administrator cannot override the scope for the same cluster policy.

What the scope rules of precedence are

The following rules of precedence apply to scope configurations:

- When a share is included in the `-shares-to-include` parameter and the parent volume of the share is included in the `-volumes-to-exclude` parameter, `-volumes-to-exclude` has precedence over `-shares-to-include`.
- When an export policy is included in the `-export-policies-to-include` parameter and the parent volume of the export policy is included in the `-volumes-to-exclude` parameter, `-volumes-to-exclude` has precedence over `-export-policies-to-include`.
- An administrator can specify both `-file-extensions-to-include` and `-file-extensions-to-exclude` lists.

  The `-file-extensions-to-exclude` parameter is checked before the `-file-extensions-to-include` parameter is checked.

What the FPolicy scope configuration contains

You can use the following list of available FPolicy scope configuration parameters to help you plan your configuration:

> When configuring what shares, export policies, volumes, and file extensions to include or exclude from the scope, the include and exclude parameters can include metacharacters such as "?" and "*". The use of regular expressions is not supported.

Type of information	Option

SVM Specifies the SVM name on which you want to create an FPolicy scope. Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.	`-vserver vserver_name`
Policy name Specifies the name of the FPolicy policy to which you want to attach the scope. The FPolicy policy must already exist.	`-policy-name policy_name`
Shares to include Specifies a comma-delimited list of shares to monitor for the FPolicy policy to which the scope is applied.	`-shares-to-include share_name`, …
Shares to exclude Specifies a comma-delimited list of shares to exclude from monitoring for the FPolicy policy to which the scope is applied.	`-shares-to-exclude share_name`, …
Volumes to include Specifies a comma-delimited list of volumes to monitor for the FPolicy policy to which the scope is applied.	`-volumes-to-include volume_name`, …
Volumes to exclude Specifies a comma-delimited list of volumes to exclude from monitoring for the FPolicy policy to which the scope is applied.	`-volumes-to-exclude volume_name`, …
Export policies to include Specifies a comma-delimited list of export policies to monitor for the FPolicy policy to which the scope is applied.	`-export-policies-to-include export_policy_name`, …
Export policies to exclude Specifies a comma-delimited list of export policies to exclude from monitoring for the FPolicy policy to which the scope is applied.	`-export-policies-to-exclude export_policy_name`, …
File extensions to include Specifies a comma-delimited list of file extensions to monitor for the FPolicy policy to which the scope is applied.	`-file-extensions-to-include file_extensions`, …

File extension to exclude Specifies a comma-delimited list of file extensions to exclude from monitoring for the FPolicy policy to which the scope is applied.	`-file-extensions-to -exclude file_extensions, …`
Is file extension check on directory enabled ? Specifies whether the file name extension checks apply to directory objects as well. If this parameter is set to `true`, the directory objects are subjected to the same extension checks as regular files. If this parameter is set to `false`, the directory names are not matched for extensions and notifications are sent for directories even if their name extensions do not match. If the FPolicy policy to which the scope is assigned is configured to use the native engine, this parameter must be set to `true`.	`-is-file-extension -check-on-directories -enabled {true| false|}`

Complete ONTAP FPolicy scope worksheets

You can use this worksheet to record the values that you need during the FPolicy scope configuration process. If a parameter value is required, you need to determine what value to use for those parameters before you configure the FPolicy scope.

You should record whether you want to include each parameter setting in the FPolicy scope configuration and then record the value for the parameters that you want to include.

Type of information	Required	Include	Your values
Storage virtual machine (SVM) name	Yes	Yes	
Policy name	Yes	Yes	
Shares to include	No		
Shares to exclude	No		
Volumes to include	No		
Volumes to exclude	No		
Export policies to include	No		
Export policies to exclude	No		
File extensions to include	No		
File extension to exclude	No		

Is file extension check on directory enabled?	No		

Create the FPolicy configuration

Create ONTAP FPolicy external engines

You must create an external engine to start creating an FPolicy configuration. The external engine defines how FPolicy makes and manages connections to external FPolicy servers. If your configuration uses the internal ONTAP engine (the native external engine) for simple file blocking, you do not need to configure a separate FPolicy external engine and do not need to perform this step.

Before you begin

The external engine worksheet should be completed.

About this task

If the external engine is used in a MetroCluster configuration, you should specify the IP addresses of the FPolicy servers at the source site as primary servers. The IP addresses of the FPolicy servers at the destination site should be specified as secondary servers.

Steps

1. Create the FPolicy external engine by using the `vserver fpolicy policy external-engine create` command.

   The following command creates an external engine on storage virtual machine (SVM) vs1.example.com. No authentication is required for external communications with the FPolicy server.

   ```
   vserver fpolicy policy external-engine create -vserver-name vs1.example.com
   -engine-name engine1 -primary-servers 10.1.1.2,10.1.1.3 -port 6789 -ssl-option
   no-auth
   ```

2. Verify the FPolicy external engine configuration by using the `vserver fpolicy policy external-engine show` command.

   The following command display information about all external engines configured on SVM vs1.example.com:

   ```
   vserver fpolicy policy external-engine show -vserver vs1.example.com
   ```

```
                              Primary        Secondary
External
Vserver              Engine       Servers        Servers        Port Engine
Type
---------------    -----------  -------------- ----------- ------
------------
vs1.example.com    engine1      10.1.1.2,      -              6789
synchronous
                                10.1.1.3
```

The following command displays detailed information about the external engine named “engine1” on SVM vs1.example.com:

```
vserver fpolicy policy external-engine show -vserver vs1.example.com -engine
-name engine1
```

```
                              Vserver: vs1.example.com
                               Engine: engine1
              Primary FPolicy Servers: 10.1.1.2, 10.1.1.3
       Port Number of FPolicy Service: 6789
            Secondary FPolicy Servers: -
                 External Engine Type: synchronous
SSL Option for External Communication: no-auth
           FQDN or Custom Common Name: -
         Serial Number of Certificate: -
                Certificate Authority: -
```

Create ONTAP FPolicy events

As part of creating an FPolicy policy configuration, you need to create an FPolicy event. You associate the event with the FPolicy policy when it is created. An event defines which protocol to monitor and which file access events to monitor and filter.

Before you begin

You should complete the FPolicy event worksheet.

Create the FPolicy event

1. Create the FPolicy event by using the `vserver fpolicy policy event create` command.

   ```
   vserver fpolicy policy event create -vserver vs1.example.com -event-name
   event1 -protocol cifs -file-operations open,close,read,write
   ```

2. Verify the FPolicy event configuration by using the `vserver fpolicy policy event show` command.

   ```
   vserver fpolicy policy event show -vserver vs1.example.com
   ```

```
                    Event                File                    Is Volume
Vserver             Name       Protocols Operations     Filters   Operation
---------------     ---------- --------- ------------- ---------
------------
vs1.example.com     event1     cifs      open, close,   -         false
                                         read, write
```

Create the FPolicy access denied events

Beginning with ONTAP 9.13.1, users can receive notifications for failed file operations due to lack of permissions. These notifications are valuable for security, ransomware protection, and governance.

1. Create the FPolicy event by using the `vserver fpolicy policy event create` command.

```
vserver fpolicy policy event create -vserver vs1.example.com -event-name
event1 -protocol cifs -monitor-fileop-failure true -file-operations open
```

Create ONTAP FPolicy persistent stores

Persistent stores can help decouple client I/O processing from FPolicy notification processing to reduce client latency. Beginning with ONTAP 9.14.1, FPolicy allows you to set up persistent stores to capture file access events for asynchronous non-mandatory policies in the SVM. Synchronous (either mandatory or non-mandatory) and asynchronous mandatory configurations are not supported.

Beginning with ONTAP 9.15.1, FPolicy persistent store configuration is simplified. The `persistent-store create` command automates volume creation for the SVM and configures the volume for the persistent store.

There are two ways to create a persistent store, depending on the ONTAP release:

- ONTAP 9.15.1 or later: When you create the persistent store, ONTAP automatically creates and configures its volume at the same time. This simplifies FPolicy persistent store configuration and implements all best practices.
- ONTAP 9.14.1: Manually create and configure a volume and then create a persistent store for the newly created volume.

Only one persistent store can be set up on each SVM. This single persistent store needs to be used for all FPolicy configurations on that SVM, even if the policies are from different partners.

Create a persistent store (ONTAP 9.15.1 or later)

Beginning with ONTAP 9.15.1, use the `fpolicy persistent-store create` command to create the FPolicy persistent store with inline volume creation and configuration. ONTAP automatically blocks the volume from external user protocol access (CIFS/NFS).

Before you begin

- The SVM where you want to create the persistent store must have at least one aggregate.
- You should have access to the aggregates available for the SVM and sufficient permissions to create

volumes.

Steps

1. Create the persistent store, which creates and configures the volume automatically:

```
vserver fpolicy persistent-store create -vserver <vserver> -persistent-store
<name> -volume <volume_name> -size <size> -autosize-mode
<off|grow|grow_shrink>
```

   - The `vserver` parameter is the name of the SVM.
   - The `persistent-store` parameter is the name of the persistent store.
   - The `volume` parameter is the name of the persistent store volume.

     > ⓘ If you want to use an existing, empty volume, use the `volume show` command to find it and specify it in the volume parameter.

   - The `size` parameter is based on the time duration for which you want to persist the events that are not delivered to the external server (partner application).

     For example, if you want 30 minutes of events to persist in a cluster with a 30K notifications per second capacity:

     Required Volume Size = 30000 x 30 x 60 x 0.6KB (average notification record size) = 32400000 KB = ~32 GB

     To find the approximate notification rate, you can either reach out to your FPolicy partner application or use the FPolicy counter `requests_dispatched_rate`.

     > ⓘ If you are using an existing volume, the size parameter is optional. If you do provide a value for the size parameter, it will modify the volume with the size you specify.

   - The `autosize-mode` parameter specifies the autosize mode for the volume. The supported autosize modes are:
     - off - The volume does not grow or shrink in size in response to the amount of used space.
     - grow - The volume automatically grows when used space in the volume is above the grow threshold.
     - grow_shrink - The volume grows or shrinks in size in response to the amount of used space.

2. Create the FPolicy policy and add the persistent store name to that policy. For more information, see Create the FPolicy policy.

Create a persistent store (ONTAP 9.14.1)

You can create a volume, and then create a persistent store to use that volume. You can then block the newly created volume from external user protocol access (CIFS/NFS).

Steps

1. Create an empty volume on the SVM that can be provisioned for the persistent store:

```
volume create -vserver <SVM Name> -volume <volume> -state <online> -policy
<default> -unix-permissions <777> -size <value> -aggregate <aggregate name>
```

```
-snapshot-policy <none>
```

It is expected that an administrator user with sufficient RBAC privileges (to create a volume) creates a volume (using the volume cli command or REST API) of the desired size and provide the name of that volume as the `-volume` in the persistent store create CLI command or REST API.

- The `vserver` parameter is the name of the SVM.
- The `volume` parameter is the name of the persistent store volume.
- The `state` parameter should be set to online so the volume is available for use.
- The `policy` parameter is set to the FPolicy service policy, if you have one already configured. If not, you can use the `volume modify` command later to add the policy.
- The `unix-permissions` parameter is optional.
- The `size` parameter is based on the time duration for which you want to persist the events that are not delivered to the external server (partner application).

  For example, if you want 30 minutes of events to persist in a cluster with a 30K notifications per second capacity:

  Required Volume Size = 30000 x 30 x 60 x 0.6KB (average notification record size) = 32400000 KB = ~32 GB

  To find the approximate notification rate, you can either reach out to your FPolicy partner application or use the FPolicy counter `requests_dispatched_rate`.

- The aggregate parameter is needed for FlexVol volumes, otherwise it is not required.
- The `snapshot-policy` parameter must be set to none. This ensures that there is no accidental restore of the snapshot leading to loss of current events and prevents possible duplicate event processing.

  If you want to use an existing, empty volume, use the `volume show` command to find it and the `volume modify` command to make any needed alterations. Ensure the policy, size, and `snapshot-policy` parameters are set correctly for the persistent store.

2. Create the persistent store:

```
vserver fpolicy persistent store create -vserver <SVM> -persistent-store
<PS_name> -volume <volume>
```

   - The `vserver` parameter is the name of the SVM.
   - The `persistent-store` parameter is the name of the persistent store.
   - The `volume` parameter is the name of the persistent store volume.

3. Create the FPolicy policy and add the persistent store name to that policy. For more information, see Create the FPolicy policy.

Create ONTAP FPolicy policies

When you create the FPolicy policy, you associate an external engine and one or more events to the policy. The policy also specifies whether mandatory screening is required, whether the FPolicy servers have privileged access to data on the storage virtual machine (SVM), and whether passthrough-read for offline files is enabled.

Before you begin

- The FPolicy policy worksheet should be completed.
- If you plan on configuring the policy to use FPolicy servers, the external engine must exist.
- At least one FPolicy event that you plan on associating with the FPolicy policy must exist.
- If you want to configure privileged data access, a SMB server must exist on the SVM.
- To configure a persistent store for a policy, the engine type must be **async** and the policy must be **non-mandatory**.

  For more information, see Create persistent stores.

Steps

1. Create the FPolicy policy:

   ```
   vserver fpolicy policy create -vserver-name vserver_name -policy-name
   policy_name -engine engine_name -events event_name, [-persistent-store
   PS_name] [-is-mandatory {true|false}] [-allow-privileged-access {yes|no}] [-
   privileged-user-name domain\user_name] [-is-passthrough-read-enabled
   {true|false}]
   ```

   - You can add one or more events to the FPolicy policy.
   - By default, mandatory screening is enabled.
   - If you want to allow privileged access by setting the `-allow-privileged-access` parameter to `yes`, you must also configure a privileged user name for privileged access.
   - If you want to configure passthrough-read by setting the `-is-passthrough-read-enabled` parameter to `true`, you must also configure privileged data access.

     The following command creates a policy named “policy1” that has the event named “event1” and the external engine named “engine1” associated with it. This policy uses default values in the policy configuration:

     ```
     vserver fpolicy policy create -vserver vs1.example.com -policy-name policy1
     -events event1 -engine engine1
     ```

     The following command creates a policy named “policy2” that has the event named “event2” and the external engine named “engine2” associated with it. This policy is configured to use privileged access using the specified user name. Passthrough-read is enabled:

     ```
     vserver fpolicy policy create -vserver vs1.example.com -policy-name policy2
     -events event2 -engine engine2 -allow-privileged-access yes -privileged-
     user-name example\archive_acct -is-passthrough-read-enabled true
     ```

     The following command creates a policy named “native1” that has the event named “event3” associated with it. This policy uses the native engine and uses default values in the policy configuration:

     ```
     vserver fpolicy policy create -vserver vs1.example.com -policy-name native1
     -events event3 -engine native
     ```

2. Verify the FPolicy policy configuration by using the `vserver fpolicy policy show` command.

   The following command displays information about the three configured FPolicy policies, including the following information:

   - The SVM associated with the policy
   - The external engine associated with the policy
   - The events associated with the policy
   - Whether mandatory screening is required
   - Whether privileged access is required
     `vserver fpolicy policy show`

```
   Vserver       Policy     Events    Engine    Is Mandatory  Privileged
                 Name                                         Access
--------------   ---------  --------- --------- ------------
-----------
vs1.example.com  policy1    event1    engine1   true          no
vs1.example.com  policy2    event2    engine2   true          yes
vs1.example.com  native1    event3    native    true          no
```

Create ONTAP FPolicy scopes

After creating the FPolicy policy, you need to create an FPolicy scope. When creating the scope, you associate the scope with an FPolicy policy. A scope defines the boundaries on which the FPolicy policy applies. Scopes can include or exclude files based on shares, export policies, volumes, and file extensions.

Before you begin

The FPolicy scope worksheet must be completed. The FPolicy policy must exist with an associated external engine (if the policy is configured to use external FPolicy servers) and must have at least one associated FPolicy event.

Steps

1. Create the FPolicy scope by using the `vserver fpolicy policy scope create` command.

   `vserver fpolicy policy scope create -vserver-name vs1.example.com -policy-name policy1 -volumes-to-include datavol1,datavol2`

2. Verify the FPolicy scope configuration by using the `vserver fpolicy policy scope show` command.

   `vserver fpolicy policy scope show -vserver vs1.example.com -instance`

```
                   Vserver: vs1.example.com
                    Policy: policy1
         Shares to Include: -
         Shares to Exclude: -
        Volumes to Include: datavol1, datavol2
        Volumes to Exclude: -
Export Policies to Include: -
Export Policies to Exclude: -
File Extensions to Include: -
File Extensions to Exclude: -
```

Enable ONTAP FPolicy policies

After you are through configuring an FPolicy policy configuration, you enable the FPolicy policy. Enabling the policy sets its priority and starts file access monitoring for the policy.

Before you begin

The FPolicy policy must exist with an associated external engine (if the policy is configured to use external FPolicy servers) and must have at least one associated FPolicy event. The FPolicy policy scope must exist and must be assigned to the FPolicy policy.

About this task

The priority is used when multiple policies are enabled on the storage virtual machine (SVM) and more than one policy has subscribed to the same file access event. Policies that use the native engine configuration have a higher priority than policies for any other engine, regardless of the sequence number assigned to them when enabling the policy.

> A policy cannot be enabled on the admin SVM.

Steps

1. Enable the FPolicy policy by using the `vserver fpolicy enable` command.

   `vserver fpolicy enable -vserver-name vs1.example.com -policy-name policy1 -sequence-number 1`

2. Verify that the FPolicy policy is enabled by using the `vserver fpolicy show` command.

   `vserver fpolicy show -vserver vs1.example.com`

```

                                    Sequence
Vserver          Policy Name         Number  Status   Engine
---------------  ----------------- --------  -------- ---------
vs1.example.com  policy1                  1  on       engine1
```

Manage FPolicy configurations

Modify FPolicy configurations

Commands modifying FPolicy configurations in ONTAP

You can modify FPolicy configurations by modifying the elements that make up the configuration. You can modify external engines, FPolicy events, FPolicy scopes, FPolicy persistent stores, and FPolicy policies. You can also enable or disable FPolicy policies. When you disable the FPolicy policy, file monitoring is discontinued for that policy.

You should disable an FPolicy policy before modifying its configuration.

If you want to modify…	Use this command…
External engines	`vserver fpolicy policy external-engine modify`
Events	`vserver fpolicy policy event modify`
Scopes	`vserver fpolicy policy scope modify`
Persistent store	`vserver fpolicy persistent-store modify`
Policies	`vserver fpolicy policy modify`

Learn more about `vserver fpolicy policy` in the ONTAP command reference.

Enable or disable ONTAP FPolicy policies

You can enable FPolicy policies after the configuration is complete. Enabling the policy sets its priority and starts file access monitoring for the policy. You can disable FPolicy policies if you want to stop file access monitoring for the policy.

Before you begin

Before enabling FPolicy policies, the FPolicy configuration must be completed.

About this task

- The priority is used when multiple policies are enabled on the storage virtual machine (SVM) and more than one policy has subscribed to the same file access event.
- Policies that use the native engine configuration have a higher priority than policies for any other engine, regardless of the sequence number assigned to them when enabling the policy.
- If you want to change the priority of an FPolicy policy, you must disable the policy and then reenable it using the new sequence number.

Step

1. Perform the appropriate action:

If you want to…	Enter the following command…
Enable an FPolicy policy	`vserver fpolicy enable -vserver-name vserver_name -policy-name policy_name -sequence-number integer`
Disable an FPolicy policy	`vserver fpolicy disable -vserver-name vserver_name -policy-name policy_name`

Display information about FPolicy configurations

Learn about ONTAP FPolicy show commands

It is helpful when displaying information about the FPolicy configuration to understand how the `show` commands work.

A `show` command without additional parameters displays information in a summary form. Additionally, every `show` command has the same two mutually exclusive optional parameters, `-instance` and `-fields`.

When you use the `-instance` parameter with a `show` command, the command output displays detailed information in a list format. In some cases, the detailed output can be lengthy and include more information than you need. You can use the `-fields fieldname[,fieldname…]` parameter to customize the output so that it displays information only for the fields you specify. You can identity which fields that you can specify by entering `?` after the `-fields` parameter.

> The output of a `show` command with the `-fields` parameter might display other relevant and necessary fields related to the requested fields.

Every `show` command has one or more optional parameters that filter that output and enable you to narrow the scope of information displayed in command output. You can identity which optional parameters are available for a command by entering `?` after the `show` command.

The `show` command supports UNIX-style patterns and wildcards to enable you to match multiple values in command-parameters arguments. For example, you can use the wildcard operator (*), the NOT operator (!), the OR operator (|), the range operator (integer…integer), the less-than operator (<), the greater-than operator (>), the less-than or equal to operator (<=), and the greater-than or equal to operator (>=) when specifying values.

For more information about using UNIX-style patterns and wildcards, see the Using the ONTAP command-line interface.

Commands for displaying information about FPolicy configurations in ONTAP

You use the `fpolicy show` commands to display information about the FPolicy configuration, including information about FPolicy external engines, events, scopes, and policies.

If you want to display information about FPolicy…	Use this command…

External engines	`vserver fpolicy policy external-engine show`
Events	`vserver fpolicy policy event show`
Scopes	`vserver fpolicy policy scope show`
Policies	`vserver fpolicy policy show`

Learn more about `vserver fpolicy policy` in the ONTAP command reference.

Display information about ONTAP FPolicy policy status

You can display information about the status for FPolicy policies to determine whether a policy is enabled, what external engine it is configured to use, what the sequence number is for the policy, and to which storage virtual machine (SVM) the FPolicy policy is associated.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Policy name
- Policy sequence number
- Policy status

In addition to displaying information about policy status for FPolicy policies configured on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output, or `-fields ?` to determine what fields you can use.

Step

1. Display filtered information about FPolicy policy status by using the appropriate command:

If you want to display status information about policies…	Enter the command…
On the cluster	`vserver fpolicy show`
That have the specified status	`vserver fpolicy show -status {on|off}`
On a specified SVM	`vserver fpolicy show -vserver vserver_name`
With the specified policy name	`vserver fpolicy show -policy-name policy_name`

That use the specified external engine	`vserver fpolicy show -engine engine_name`

Example

The following example displays the information about FPolicy policies on the cluster:

```
cluster1::> vserver fpolicy show
                                           Sequence
Vserver              Policy Name             Number  Status      Engine
-------------------- -------------------- --------  ---------   ---------
FPolicy              cserver_policy       -         off         eng1
vs1.example.com      v1p1                 -         off         eng2
vs1.example.com      v1p2                 -         off         native
vs1.example.com      v1p3                 -         off         native
vs1.example.com      cserver_policy       -         off         eng1
vs2.example.com      v1p1                 3         on          native
vs2.example.com      v1p2                 1         on          eng3
vs2.example.com      cserver_policy       2         on          eng1
```

Display information about enabled ONTAP FPolicy policies

You can display information about enabled FPolicy policies to determine what FPolicy external engine it is configured to use, what the priority is for the policy, and to which storage virtual machine (SVM) the FPolicy policy is associated.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Policy name
- Policy priority

You can use command parameters to filter the command's output by specified criteria.

Step

1. Display information about enabled FPolicy policies by using the appropriate command:

If you want to display information about enabled policies…	Enter the command…
On the cluster	`vserver fpolicy show-enabled`
On a specified SVM	`vserver fpolicy show-enabled -vserver vserver_name`

With the specified policy name	`vserver fpolicy show-enabled -policy-name policy_name`
With the specified sequence number	`vserver fpolicy show-enabled -priority integer`

Example

The following example displays the information about enabled FPolicy policies on the cluster:

```
cluster1::> vserver fpolicy show-enabled
Vserver                 Policy Name               Priority

----------------------- ------------------------- ----------
vs1.example.com         pol_native                native
vs1.example.com         pol_native2               native
vs1.example.com         pol1                      2
vs1.example.com         pol2                      4
```

Manage FPolicy server connections

Connect to external FPolicy servers in ONTAP

To enable file processing, you might need to manually connect to an external FPolicy server if the connection has previously been terminated. A connection is terminated after the server timeout is reached or due to some error. Alternatively, the administrator might manually terminate a connection.

About this task

If a fatal error occurs, the connection to the FPolicy server can be terminated. After resolving the issue that caused the fatal error, you must manually reconnect to the FPolicy server.

Steps

1. Connect to the external FPolicy server by using the `vserver fpolicy engine-connect` command.

   Learn more about `vserver fpolicy engine-connect` in the ONTAP command reference.

2. Verify that the external FPolicy server is connected by using the `vserver fpolicy show-engine` command.

   Learn more about `vserver fpolicy show-engine` in the ONTAP command reference.

Disconnect from external FPolicy servers in ONTAP

You might need to manually disconnect from an external FPolicy server. This might be desirable if the FPolicy server has issues with notification request processing or if you need to perform maintenance on the FPolicy server.

Steps

1. Disconnect from the external FPolicy server by using the `vserver fpolicy engine-disconnect` command.

   Learn more about `vserver fpolicy engine-disconnect` in the ONTAP command reference.

2. Verify that the external FPolicy server is disconnected by using the `vserver fpolicy show-engine` command.

   Learn more about `vserver fpolicy show-engine` in the ONTAP command reference.

Display information about connections to external ONTAP FPolicy servers

You can display status information about connections to external FPolicy servers (FPolicy servers) for the cluster or for a specified storage virtual machine (SVM). This information can help you determine which FPolicy servers are connected.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Node name
- FPolicy policy name
- FPolicy server IP address
- FPolicy server status
- FPolicy server type

In addition to displaying information about FPolicy connections on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output. You can enter `?` after the `-fields` parameter to find out which fields you can use.

Step

1. Display filtered information about connection status between the node and the FPolicy server by using the appropriate command:

If you want to display connection status information about FPolicy servers…	Enter…
That you specify	`vserver fpolicy show-engine -server IP_address`
For a specified SVM	`vserver fpolicy show-engine -vserver vserver_name`
That are attached with a specified policy	`vserver fpolicy show-engine -policy-name policy_name`

With the server status that you specify	`vserver fpolicy show-engine -server-status status` The server status can be one of the following: • `connected` • `disconnected` • `connecting` • `disconnecting`
With the specified type	`vserver fpolicy show-engine -server-type type` The FPolicy server type can be one of the following: • `primary` • `secondary`
That were disconnected with the specified reason	`vserver fpolicy show-engine -disconnect-reason text` Disconnect can be due to multiple reasons. The following are common reasons for disconnect: • `Disconnect command received from CLI.` • `Error encountered while parsing notification response from FPolicy server.` • `FPolicy Handshake failed.` • `SSL handshake failed.` • `TCP Connection to FPolicy server failed.` • `The screen response message received from the FPolicy server is not valid.`

Example

This example displays information about external engine connections to FPolicy servers on SVM vs1.example.com:

```
cluster1::> vserver fpolicy show-engine -vserver vs1.example.com
FPolicy                                                 Server-       Server-
Vserver          Policy    Node         Server          status        type
--------------- --------- ------------ ------------- -------------
---------
vs1.example.com policy1   node1        10.1.1.2      connected     primary
vs1.example.com policy1   node1        10.1.1.3      disconnected  primary
vs1.example.com policy1   node2        10.1.1.2      connected     primary
vs1.example.com policy1   node2        10.1.1.3      disconnected  primary
```

This example displays information only about connected FPolicy servers:

```
cluster1::> vserver fpolicy show-engine -fields server -server-status
connected
node       vserver         policy-name server
---------- --------------- ----------- -------
node1      vs1.example.com policy1     10.1.1.2
node2      vs1.example.com policy1     10.1.1.2
```

Display information about ONTAP FPolicy passthrough-read connection status

You can display information about FPolicy passthrough-read connection status to external FPolicy servers (FPolicy servers) for the cluster or for a specified storage virtual machine (SVM). This information can help you determine which FPolicy servers have passthrough-read data connections and for which FPolicy servers the passthrough-read connection is disconnected.

About this task

If you do not specify any parameter, the command displays the following information:

- SVM name
- FPolicy policy name
- Node name
- FPolicy server IP address
- FPolicy passthrough-read connection status

In addition to displaying information about FPolicy connections on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output. You can enter `?` after the `-fields` parameter to find out which fields you can use.

Step

1. Display filtered information about connection status between the node and the FPolicy server by using the

appropriate command:

If you want to display connection status information about…	Enter the command…
FPolicy passthrough-read connection status for the cluster	`vserver fpolicy show-passthrough-read-connection`
FPolicy passthrough-read connection status for a specified SVM	`vserver fpolicy show-passthrough-read-connection -vserver vserver_name`
FPolicy passthrough-read connection status for a specified policy	`vserver fpolicy show-passthrough-read-connection -policy-name policy_name`
Detailed FPolicy passthrough-read connection status for a specified policy	`vserver fpolicy show-passthrough-read-connection -policy-name policy_name -instance`
FPolicy passthrough-read connection status for the status that you specify	`vserver fpolicy show-passthrough-read-connection -policy-name policy_name -server-status status` The server status can be one of the following: • `connected` • `disconnected`

Example

The following command displays information about passthrough-read connections from all FPolicy servers on the cluster:

```
cluster1::> vserver fpolicy show-passthrough-read-connection
                                             FPolicy            Server
Vserver           Policy Name   Node         Server             Status
---------------   ------------- ------------ -----------------
--------------
vs2.example.com   pol_cifs_2    FPolicy-01   2.2.2.2            disconnected
vs1.example.com   pol_cifs_1    FPolicy-01   1.1.1.1            connected
```

The following command displays detailed information about passthrough-read connections from FPolicy servers configured in the “pol_cifs_1” policy:

```
cluster1::> vserver fpolicy show-passthrough-read-connection -policy-name
pol_cifs_1 -instance

                                             Node: FPolicy-01
                                          Vserver: vs1.example.com
                                           Policy: pol_cifs_1
                                           Server: 1.1.1.1
                Session ID of the Control Channel: 8cef052e-2502-11e3-
88d4-123478563412
                                    Server Status: connected
      Time Passthrough Read Channel was Connected: 9/24/2013 10:17:45
   Time Passthrough Read Channel was Disconnected: -
Reason for Passthrough Read Channel Disconnection: none
```

Verify access using security tracing

Learn about ONTAP security traces

You can add permission tracing filters to instruct ONTAP to log information about why the SMB and NFS servers on a storage virtual machine (SVM) allows or denies a client or user’s request to perform an operation. This can be useful when you want to verify that your file access security scheme is appropriate or when you want to troubleshoot file access issues.

Security traces allow you to configure a filter that detects client operations over SMB and NFS on the SVM, and trace all access checks matching that filter. You can then view the trace results, which provides a convenient summary of the reason that access was allowed or denied.

When you want to verify the security settings for SMB or NFS access on files and folders on your SVM or if you are faced with an access problem, you can quickly add a filter to turn on permission tracing.

The following list outlines important facts about how security traces works:

- ONTAP applies security traces at the SVM level.
- Each incoming request is screened to see if it matches filtering criteria of any enabled security traces.
- Traces are performed for both file and folder access requests.
- Traces can filter based on the following criteria:
  - Client IP
  - SMB or NFS path
  - Windows name
  - UNIX name
- Requests are screened for *Allowed* and *Denied* access response results.
- Each request matching filtering criteria of enabled traces is recorded in the trace results log.
- The storage administrator can configure a timeout on a filter to automatically disable it.

- If a request matches multiple filters, the results from the filter with the highest index number is recorded.
- The storage administrator can print results from the trace results log to determine why an access request was allowed or denied.

Types of access checks security traces monitor on ONTAP SVMs

Access checks for a file or folder are done based on multiple criteria. Security traces monitor operations on all these criteria.

The types of access checks that security traces monitor include the following:

- Volume and qtree security style
- Effective security of the file system containing the files and folders on which operations are requested
- User mapping
- Share-level permissions
- Export-level permissions
- File-level permissions
- Storage-Level Access Guard security

Considerations when creating security traces on ONTAP SVMs

You should keep several considerations in mind when you create security traces on storage virtual machines (SVMs). For example, you need to know on which protocols you can create a trace, which security-styles are supported, and what the maximum number of active traces is.

- You can only create security traces on SVMs.
- Each security trace filter entry is SVM specific.

  You must specify the SVM on which you want to run the trace.

- You can add permission tracing filters for SMB and NFS requests.
- You must set up the SMB or NFS server on the SVM on which you want to create trace filters.
- You can create security traces for files and folders residing on NTFS, UNIX, and mixed security-style volumes and qtrees.
- You can add a maximum of 10 permission tracing filters per SVM.
- You must specify a filter index number when creating or modifying a filter.

  Filters are considered in order of the index number. The criteria in a filter with a higher index number is considered before the criteria with a lower index number. If the request being traced matches criteria in multiple enabled filters, only the filter with the highest index number is triggered.

- After you have created and enabled a security trace filter, you must perform some file or folder requests on a client system to generate activity that the trace filter can capture and log in the trace results log.
- You should add permission tracing filters for file access verification or troubleshooting purposes only.

  Adding permission tracing filters has a minor effect on controller performance.

When you are done with verification or troubleshooting activity, you should disable or remove all permission tracing filters. Furthermore, the filtering criteria you select should be as specific as possible so that ONTAP does not send a large number of trace results to the log.

Perform security traces

Learn to perform ONTAP security traces

Performing a security trace involves creating a security trace filter, verifying the filter criteria, generating access requests on an SMB or NFS client that match filter criteria, and viewing the results.

After you are finished using a security filter to capture trace information, you can modify the filter and reuse it, or disable it if you no longer need it. After viewing and analyzing the filter trace results, you can then delete them if they are no longer needed.

Create security trace filters in ONTAP SVMs

You can create security trace filters that detect SMB and NFS client operations on storage virtual machines (SVMs)and trace all access checks matching the filter. You can use the results from security traces to validate your configuration or to troubleshoot access issues.

About this task

There are two required parameters for the vserver security trace filter create command:

Required parameters	Description
`-vserver` `vserver_name`	*SVM name* The name of the SVM that contains the files or folders on which you want to apply the security trace filter.
`-index` `index_number`	*Filter index number* The index number you want to apply to the filter. You are limited to a maximum of 10 trace filters per SVM. The allowed values for this parameter are 1 through 10.

A number of optional filter parameters enable you to customize the security trace filter so that you can narrow down the results produced by the security trace:

Filter parameter	Description
`-client-ip` `IP_Address`	This filter specifies the IP address from which the user is accessing the SVM.

`-path` path	This filter specifies the path on which to apply the permission trace filter. The value for `-path` can use either of the following formats: • The complete path, starting from the root of the share or export • A partial path, relative to the root of the share You must use NFS style directory UNIX-style directory separators in the path value.
`-windows-name` `win_user_name` or `-unix -name``unix_user_name`	You can specify either the Windows user name or UNIX user name whose access requests you want to trace. The user name variable is case insensitive. You cannot specify both a Windows user name and a UNIX user name in the same filter. ⓘ Even though you can trace SMB and NFS access events, the mapped UNIX user and the mapped UNIX users' groups might be used when performing access checks on mixed or UNIX security-style data.
`-trace-allow` {`yes`|`no`}	Tracing for deny events is always enabled for a security trace filter. You can optionally trace allow events. To trace allow events, you set this parameter to `yes`.
`-enabled` {`enabled`|`disabled`}	You can enable or disable the security trace filter. By default, the security trace filter is enabled.
`-time-enabled` `integer`	You can specify a timeout for the filter, after which it is disabled.

Steps

1. Create a security trace filter:

   `vserver security trace filter create -vserver vserver_name -index index_numberfilter_parameters`

   `filter_parameters` is a list of optional filter parameters.

   Learn more about `vserver security trace filter create` in the ONTAP command reference.

2. Verify the security trace filter entry:

   `vserver security trace filter show -vserver vserver_name -index index_number`

Examples

The following command creates a security trace filter for any user accessing a file with a share path `\\server\share1\dir1\dir2\file.txt` from the IP address 10.10.10.7. The filter uses a complete path for the `-path` option. The client's IP address used to access data is 10.10.10.7. The filter times out after 30 minutes:

```
cluster1::> vserver security trace filter create -vserver vs1 -index 1
-path /dir1/dir2/file.txt -time-enabled 30 -client-ip 10.10.10.7
cluster1::> vserver security trace filter show -index 1
Vserver  Index   Client-IP            Path            Trace-Allow
Windows-Name
-------- -----  -----------  ----------------------   -----------
-------------
vs1        1    10.10.10.7   /dir1/dir2/file.txt          no       -
```

The following command creates a security trace filter using a relative path for the `-path` option. The filter traces access for a Windows user named “joe”. Joe is accessing a file with a share path `\\server\share1\dir1\dir2\file.txt`. The filter traces allow and deny events:

```
cluster1::> vserver security trace filter create -vserver vs1 -index 2
-path /dir1/dir2/file.txt -trace-allow yes -windows-name mydomain\joe

cluster1::> vserver security trace filter show -vserver vs1 -index 2
                                 Vserver: vs1
                            Filter Index: 2
              Client IP Address to Match: -
                                    Path: /dir1/dir2/file.txt
                       Windows User Name: mydomain\joe
                          UNIX User Name: -
                      Trace Allow Events: yes
                          Filter Enabled: enabled
               Minutes Filter is Enabled: 60
```

Display information about security trace filters in ONTAP SVMs

You can display information about security trace filters configured on your storage virtual machine (SVM). This enables you to see which types of access events each filter traces.

Step

1. Display information about security trace filter entries by using the `vserver security trace filter show` command.

   Learn more about `vserver security trace filter show` in the ONTAP command reference.

Examples

The following command displays information about all security trace filters on SVM vs1:

```
cluster1::> vserver security trace filter show -vserver vs1
Vserver  Index   Client-IP            Path            Trace-Allow
Windows-Name
-------- -----  -----------  ----------------------   -----------
-------------
vs1        1    -            /dir1/dir2/file.txt          yes      -
vs1        2    -            /dir3/dir4/                  no
mydomain\joe
```

Display security trace results in ONTAP SVMs

You can display the security trace results generated for file operations that match security trace filters. You can use the results to validate your file access security configuration or to troubleshoot SMB and NFS file access issues.

Before you begin

An enabled security trace filter must exist and operations must have been performed from an SMB or NFS client that matches the security trace filter to generate security trace results.

About this task

You can display a summary of all security trace results, or you can customize what information is displayed in the output by specifying optional parameters. This can be helpful when the security trace results contain a large number of records.

If you do not specify any of the optional parameters, the following is displayed:

- storage virtual machine (SVM) name
- Node name
- Security trace index number
- Security style
- Path
- Reason
- User name

  The user name is displayed depending on how the trace filter is configured:

If the filter is configured…	Then…
With a UNIX user name	The security trace result displays the UNIX user name.
With a Windows user name	The security trace result displays the Windows user name.
Without a user name	The security trace result displays the Windows user name.

You can customize the output by using optional parameters. Some of the optional parameters that you can use to narrow the results returned in the command output include the following:

Optional parameter	Description
`-fields field_name, …`	Displays output on the fields you choose. You can use this parameter either alone or in combination with other optional parameters.
`-instance`	Displays detailed information about security trace events. Use this parameter with other optional parameters to display detailed information about specific filter results.
`-node node_name`	Displays information only about events on the specified node.
`-vserver vserver_name`	Displays information only about events on the specified SVM.
`-index integer`	Displays information about the events that occurred as a result of the filter corresponding to the specified index number.
`-client-ip IP_address`	Displays information about the events that occurred as a result of file access from the specified client IP address.
`-path path`	Displays information about the events that occurred as a result of file access to the specified path.
`-user-name user_name`	Displays information about the events that occurred as a result of file access by the specified Windows or UNIX user.
`-security-style security_style`	Displays information about the events that occurred on file systems with the specified security style.

Learn more about other optional parameters in the ONTAP command reference.

Step

1. Display security trace filter results by using the `vserver security trace trace-result show` command.

   ```
   vserver security trace trace-result show -user-name domain\user
   ```

```
Vserver: vs1

Node     Index   Filter Details         Reason
-------- ------- ---------------------  -----------------------------
node1    3       User:domain\user       Access denied by explicit ACE
                 Security Style:mixed
                 Path:/dir1/dir2/

node1    5       User:domain\user       Access denied by explicit ACE
                 Security Style:unix
                 Path:/dir1/
```

Modify security trace filters on ONTAP SVMs

If you want to change the optional filter parameters used to determine which access events are traced, you can modify existing security trace filters.

About this task

You must identify which security trace filter you want to modify by specifying the storage virtual machine (SVM) name on which the filter is applied and the index number of the filter. You can modify all the optional filter parameters.

Steps

1. Modify a security trace filter:

   ```
   vserver security trace filter modify -vserver vserver_name -index
   index_numberfilter_parameters
   ```

   - `vserver_name` is the name of the SVM on which you want to apply a security trace filter.
   - `index_number` is the index number that you want to apply to the filter. The allowed values for this parameter are 1 through 10.
   - `filter_parameters` is a list of optional filter parameters.

2. Verify the security trace filter entry:

   ```
   vserver security trace filter show -vserver vserver_name -index index_number
   ```

Example

The following command modifies the security trace filter with the index number 1. The filter traces events for any user accessing a file with a share path `\\server\share1\dir1\dir2\file.txt` from any IP address. The filter uses a complete path for the `-path` option. The filter traces allow and deny events:

```
cluster1::> vserver security trace filter modify -vserver vs1 -index 1
-path /dir1/dir2/file.txt -trace-allow yes

cluster1::> vserver security trace filter show -vserver vs1 -index 1
                                 Vserver: vs1
                            Filter Index: 1
              Client IP Address to Match: -
                                    Path: /dir1/dir2/file.txt
                       Windows User Name: -
                          UNIX User Name: -
                      Trace Allow Events: yes
                          Filter Enabled: enabled
               Minutes Filter is Enabled: 60
```

Delete security trace filters on ONTAP SVMs

When you no longer need a security trace filter entry, you can delete it. Because you can have a maximum of 10 security trace filters per storage virtual machine (SVM), deleting unneeded filters enables you to create new filters if you have reached the maximum.

About this task

To uniquely identify the security trace filter that you want to delete, you must specify the following:

- The name of the SVM to which the trace filter is applied
- The filter index number of the trace filter

Steps

1. Identify the filter index number of the security trace filter entry you want to delete:

   `vserver security trace filter show -vserver vserver_name`

   `vserver security trace filter show -vserver vs1`

   ```
   Vserver  Index   Client-IP            Path            Trace-Allow
   Windows-Name
   -------- -----  -----------  ----------------------   -----------
   -------------
   vs1        1    -            /dir1/dir2/file.txt          yes      -
   vs1        2    -            /dir3/dir4/                  no
   mydomain\joe
   ```

2. Using the filter index number information from the previous step, delete the filter entry:

   `vserver security trace filter delete -vserver vserver_name -index index_number`

   `vserver security trace filter delete -vserver vs1 -index 1`

3. Verify that the security trace filter entry is deleted:

   `vserver security trace filter show -vserver vserver_name`

   `vserver security trace filter show -vserver vs1`

```
Vserver  Index   Client-IP           Path            Trace-Allow
Windows-Name
-------- -----  -----------  ----------------------   -----------
-------------
vs1        2    -            /dir3/dir4/                  no
mydomain\joe
```

Delete security trace records on ONTAP SVMs

After you finish using a filter trace record to verify file access security or to troubleshoot SMB or NFS client access issues, you can delete the security trace record from the security trace log.

About this task

Before you can delete a security trace record, you must know the record's sequence number.

> Each storage virtual machine (SVM) can store a maximum of 128 trace records. If the maximum is reached on the SVM, the oldest trace records are automatically deleted as new ones are added. If you do not want to manually delete trace records on this SVM, you can let ONTAP automatically delete the oldest trace results after the maximum is reached to make room for new results.

Steps

1. Identify the sequence number of the record you want to delete:

   `vserver security trace trace-result show -vserver vserver_name -instance`

2. Delete the security trace record:

   `vserver security trace trace-result delete -node node_name -vserver vserver_name -seqnum integer`

   `vserver security trace trace-result delete -vserver vs1 -node node1 -seqnum 999`

   - `-node node_name` is the name of the cluster node on which the permission tracing event that you want to delete occurred.

     This is a required parameter.

   - `-vserver vserver_name` is the name of the SVM on which the permission tracing event that you want to delete occurred.

This is a required parameter.

- `-seqnum integer` is the sequence number of the log event that you want to delete.

  This is a required parameter.

Delete all security trace records on ONTAP SVMs

If you do not want to keep any of the existing security trace records, you can delete all of the records on a node with a single command.

Step

1. Delete all security trace records:

   `vserver security trace trace-result delete -node node_name -vserver vserver_name *`

   - `-node node_name` is the name of the cluster node on which the permission tracing event that you want to delete occurred.
   - `-vserver vserver_name` is the name of the storage virtual machine (SVM) on which the permission tracing event that you want to delete occurred.

Interpret ONTAP security trace results

Security trace results provide the reason that a request was allowed or denied. Output displays the result as a combination of the reason for allowing or denying access and the location within the access checking pathway where access is either allowed or denied. You can use the results to isolate and identify why actions are or are not allowed.

Finding information about the lists of result types and filter details

You can find the lists of result types and filter details that can be included in the security trace results in the `vserver security trace trace-result show` command.
Learn more about `vserver security trace trace-result show` in the ONTAP command reference.

Example of output from the `Reason` field in an `Allow` result type

The following is an example of the output from the `Reason` field that appears in the trace results log in an `Allow` result type:

```
Access is allowed because SMB implicit permission grants requested
access while opening existing file or directory.
```

```
Access is allowed because NFS implicit permission grants requested
access while opening existing file or directory.
```

Example of output from the `Reason` field in an `Allow` result type

The following is an example of the output from the `Reason` field that appears in the trace results log in a `Deny` result type:

```
Access is denied. The requested permissions are not granted by the
ACE while checking for child-delete access on the parent.
```

Example of output from the `Filter details` field

The following is an example of the output from the `Filter details` field in the trace results log, which list the effective security style of the file system containing files and folders that match the filter criteria:

```
Security Style: MIXED and ACL
```

Where to find additional information on ONTAP SVMs

After you have successfully tested SMB client access, you can perform advanced SMB configuration or add SAN access. After you have successfully tested NFS client access, you can perform advanced NFS configuration or add SAN access. When protocol access is complete, you should protect the root volume of SVM.

SMB configuration

You can further configure SMB access using the following:

- SMB management

  Describes how to configure and manage file access using the SMB protocol.

- NetApp Technical Report 4191: Best Practices Guide for Clustered Data ONTAP 8.2 Windows File Services

  Provides a brief overview of SMB implementation and other Windows File Services features with recommendations and basic troubleshooting information for ONTAP.

- NetApp Technical Report 3740: SMB 2 Next-Generation CIFS Protocol in Data ONTAP

  Describes SMB 2 features, configuration details, and its implementation in ONTAP.

NFS configuration

You can further configure NFS access using the following:

- NFS management

  Describes how to configure and manage file access using the NFS protocol.

- NetApp Technical Report 4067: NFS Best Practice and Implementation Guide

  Serves as an NFSv3 and NFSv4 operational guide and provides an overview of ONTAP operating system with a focus on NFSv4.

- NetApp Technical Report 4668: Name Services Best Practices Guide

  Provides a comprehensive list of best practices, limits, recommendations, and considerations when configuring LDAP, NIS, DNS, and local user and group files for authentication purposes.

- NetApp Technical Report 4616: NFS Kerberos in ONTAP with Microsoft Active Directory
- NetApp Technical Report 4835: How to Configure LDAP in ONTAP
- NetApp Technical Report 3580: NFSv4 Enhancements and Best Practices Guide Data ONTAP Implementation

  Describes the best practices that should be followed while implementing NFSv4 components on AIX, Linux, or Solaris clients attached to systems running ONTAP.

Root volume protection

After configuring protocols on the SVM, you should ensure that its root volume is protected:

- Data protection

  Describes how to create a load-sharing mirror to protect the SVM root volume, which is a NetApp best practice for NAS-enabled SVMs. Also describes how to quickly recover from volume failures or losses by promoting the SVM root volume from a load-sharing mirror.

Manage encryption with System Manager

Encrypt stored data in your ONTAP cluster using software-based encryption

Use volume encryption to ensure that volume data cannot be read if the underlying device is repurposed, returned, misplaced, or stolen. Volume encryption does not require special disks; it works with all HDDs and SSDs.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to enable software level encryption. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

Volume encryption requires a key manager. You can configure the Onboard Key Manager using System Manager. You can also use an external key manager, but you need to first set it up using the ONTAP CLI.

After the key manager is configured, new volumes are encrypted by default.

Steps

1. Click **Cluster > Settings**.
2. Under **Encryption**, click ⚙ to configure the Onboard Key Manager for the first time.
3. To encrypt existing volumes, click **Storage > Volumes**.
4. On the desired volume, click ⋮ and then click **Edit**.
5. Select **Enable encryption**.

Encrypt stored data in your ONTAP cluster using self-encrypting drives

Use disk encryption to ensure that all data in a local tier cannot be read if the underlying device is repurposed, returned, misplaced, or stolen. Disk encryption requires special self-encrypting HDDs or SSDs.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to enable hardware level encryption. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

Disk encryption requires a key manager. You can configure the onboard key manager using System Manager. You can also use an external key manager, but you need to first set it up using the ONTAP CLI.

If ONTAP detects self-encrypting disks, it prompts you to configure the onboard key manager when you create the local tier.

Steps

1. Under **Encryption**, click ⚙ to configure the onboard key manager.
2. If you see a message that disks need to be rekeyed, click ⋮, and then click **Rekey Disks**.

Manage encryption with the CLI

Learn about ONTAP data at rest encryption

NetApp offers both software- and hardware-based encryption technologies for ensuring that data at rest cannot be read if the storage medium is repurposed, returned, misplaced, or stolen.

- Software-based encryption using NetApp Volume Encryption (NVE) supports data encryption one volume at a time
- Hardware-based encryption using NetApp Storage Encryption (NSE) supports full-disk encryption (FDE) of data as it is written.

Configure NetApp volume and aggregate encryption

Learn about ONTAP NetApp volume and aggregate encryption

NetApp Volume Encryption (NVE) is a software-based technology for encrypting data at rest one volume at a time. An encryption key accessible only to the storage system ensures that volume data cannot be read if the underlying device is repurposed, returned, misplaced, or stolen.

Understanding NVE

With NVE, both metadata and data (including snapshots) are encrypted. Access to the data is given by a unique XTS-AES-256 key, one per volume. An external key management server or Onboard Key Manager (OKM) serves keys to nodes:

- The external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP). It is a best practice to configure external key management servers on a different storage system from your data.

* The Onboard Key Manager is a built-in tool that serves keys to nodes from the same storage system as your data.

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager. The VE license is included with ONTAP One. Whenever an external or onboard key manager is configured there is a change in how the encryption of data at rest is configured for brand new aggregates and brand new volumes. Brand new aggregates will have NetApp Aggregate Encryption (NAE) enabled by default. Brand new volumes that are not part of an NAE aggregate will have NetApp Volume Encryption (NVE) enabled by default. If a data storage virtual machine (SVM) is configured with its own key-manager using multi-tenant key management, then the volume created for that SVM is automatically configured with NVE.

You can enable encryption on a new or existing volume. NVE supports the full range of storage efficiency features, including deduplication and compression. Beginning with ONTAP 9.14.1, you can enable NVE on existing SVM root volumes.

> If you are using SnapLock, you can enable encryption only on new, empty SnapLock volumes. You cannot enable encryption on an existing SnapLock volume.

You can use NVE on any type of aggregate (HDD, SSD, hybrid, array LUN), with any RAID type, and in any supported ONTAP implementation, including ONTAP Select. You can also use NVE with hardware-based encryption to “double encrypt” data on self-encrypting drives.

When NVE is enabled, the core dump is also encrypted.

Aggregate-level encryption

Ordinarily, every encrypted volume is assigned a unique key. When the volume is deleted, the key is deleted with it.

Beginning with ONTAP 9.6, you can use *NetApp Aggregate Encryption (NAE)* to assign keys to the containing aggregate for the volumes to be encrypted. When an encrypted volume is deleted, the keys for the aggregate are preserved. The keys are deleted if the entire aggregate is deleted.

You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication. Aggregate-level deduplication is otherwise not supported by NVE.

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager.

NVE and NAE volumes can coexist on the same aggregate. Volumes encrypted under aggregate-level encryption are NAE volumes by default. You can override the default when you encrypt the volume.

You can use the `volume move` command to convert an NVE volume to an NAE volume, and vice versa. You can replicate an NAE volume to an NVE volume.

You cannot use `secure purge` commands on an NAE volume.

When to use external key management servers

Although it is less expensive and typically more convenient to use the onboard key manager, you should set up KMIP servers if any of the following are true:

* Your encryption key management solution must comply with Federal Information Processing Standards (FIPS) 140-2 or the OASIS KMIP standard.
* You need a multi-cluster solution, with centralized management of encryption keys.
* Your business requires the added security of storing authentication keys on a system or in a location different from the data.

Scope of external key management

The scope of external key management determines whether key management servers secure all the SVMs in the cluster or selected SVMs only:

* You can use a *cluster scope* to configure external key management for all the SVMs in the cluster. The cluster administrator has access to every key stored on the servers.
* Beginning with ONTAP 9.6, you can use an *SVM scope* to configure external key management for a named SVM in the cluster. That's best for multitenant environments in which each tenant uses a different SVM (or set of SVMs) to serve data. Only the SVM administrator for a given tenant has access to the keys for that tenant.
    * Beginning with ONTAP 9.17.1, you can use Barbican KMS to protect NVE keys only for data SVMs.
    * Beginning with ONTAP 9.10.1, you can use Azure Key Vault and Google Cloud KMS to protect NVE keys only for data SVMs. This is available for AWS's KMS beginning in 9.12.0.

You can use both scopes in the same cluster. If key management servers have been configured for an SVM, ONTAP uses only those servers to secure keys. Otherwise, ONTAP secures keys with the key management servers configured for the cluster.

A list of validated external key managers is available in the NetApp Interoperability Matrix Tool (IMT). You can find this list by entering the term "key managers" into the IMT's search feature.

> Cloud KMS providers such as Azure Key Vault and AWS KMS do not support KMIP. As a result, they are not listed on IMT.

Support details

The following table shows NVE support details:

Resource or feature	Support details
Platforms	AES-NI offload capability required. See the Hardware Universe (HWU) to verify that NVE and NAE are supported for your platform.

<table>
<tr><td>Encryption</td><td>Beginning with ONTAP 9.7, newly created aggregates and volumes are encrypted by default when you add a volume encryption (VE) license and have an onboard or external key manager configured. If you need to create an unencrypted aggregate, use the following command:

<code>storage aggregate create -encrypt-with-aggr-key false</code>

If you need to create a plain text volume, use the following command:

<code>volume create -encrypt false</code>

Encryption is not enabled by default when:
VE license is not installed.
Key manager is not configured.
Platform or software does not support encryption.
Hardware encryption is enabled.</td></tr>
<tr><td>ONTAP</td><td>All ONTAP implementations. Support for Cloud Volumes ONTAP is available in ONTAP 9.5 and later.</td></tr>
<tr><td>Devices</td><td>HDD, SSD, hybrid, array LUN.</td></tr>
<tr><td>RAID</td><td>RAID0, RAID4, RAID-DP, RAID-TEC.</td></tr>
<tr><td>Volumes</td><td>Data volumes and existing SVM root volumes. You cannot encrypt data on MetroCluster metadata volumes. In versions of ONTAP earlier than 9.14.1, you cannot encrypt data on the SVM root volume with NVE. Beginning with ONTAP 9.14.1, ONTAP supports NVE on SVM root volumes.</td></tr>
<tr><td>Aggregate-level encryption</td><td>Beginning with ONTAP 9.6, NVE supports aggregate-level encryption (NAE):
You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication.
You cannot rekey an aggregate-level encryption volume.
Secure-purge is not supported on aggregate-level encryption volumes.
In addition to data volumes, NAE supports encryption of SVM root volumes and the MetroCluster metadata volume. NAE does not support encryption of the root volume.</td></tr>
<tr><td>SVM scope</td><td>MetroCluster is supported beginning with ONTAP 9.8.

Beginning with ONTAP 9.6, NVE supports SVM scope for external key management only, not for Onboard Key Manager.</td></tr>
</table>

Storage efficiency	Deduplication, compression, compaction, FlexClone. Clones use the same key as the parent, even after splitting the clone from the parent. You should perform a `volume move` on a split clone, after which the split clone will have a different key.
Replication	• For volume replication, the source and destination volumes can have different encryption settings. Encryption can be configured for the source and unconfigured for the destination, and vice versa. Configured encryption on the source will not be replicated to the destination. Encryption must be configured manually on the source and destination. Refer to Configure NVE and Encrypt volume data with NVE. • For SVM replication, the destination volume is automatically encrypted, unless the destination does not contain a node that supports volume encryption, in which case replication succeeds, but the destination volume is not encrypted. • For MetroCluster configurations, each cluster pulls external key management keys from its configured key servers. OKM keys are replicated to the partner site by the configuration replication service.
Compliance	SnapLock is supported in both Compliance and Enterprise modes, for new volumes only. You cannot enable encryption on an existing SnapLock volume.
FlexGroup volumes	FlexGroup volumes are supported. Destination aggregates must be of the same type as source aggregates, either volume-level or aggregate-level. Beginning with ONTAP 9.5, in-place rekey of FlexGroup volumes is supported.
7-Mode transition	Beginning with 7-Mode Transition Tool 3.3, you can use the 7-Mode Transition Tool CLI to perform copy-based transition to NVE-enabled destination volumes on the clustered system.

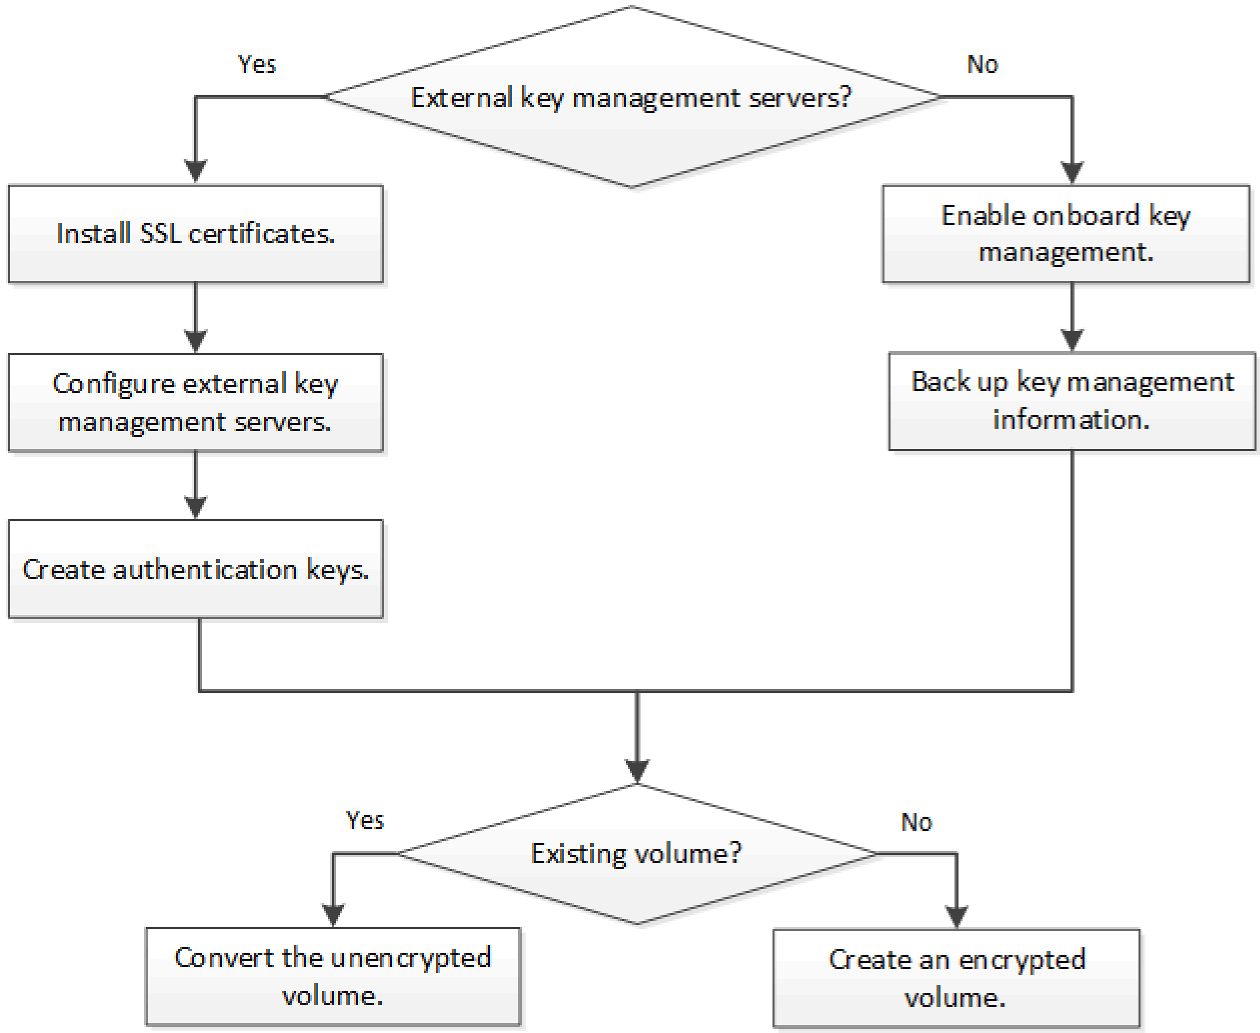
ONTAP NetApp Volume Encryption workflow

You must configure key management services before you can enable volume encryption. You can enable encryption on a new volume or on an existing volume.



You must install the VE license and configure key management services before you can encrypt data with NVE. Before installing the license, you should determine whether your ONTAP version supports NVE.

Configure NVE

Determine whether your ONTAP cluster version supports NVE

You should determine whether your cluster version supports NVE before you install the license. You can use the `version` command to determine the cluster version.

About this task

The cluster version is the lowest version of ONTAP running on any node in the cluster.

Steps

1. Determine whether your cluster version supports NVE:

   ```
   version -v
   ```

   NVE is not supported if the command output displays the text `1Ono-DARE` (for "no Data At Rest Encryption"), or if you are using a platform that is not listed in Support details.

Install the volume encryption license on an ONTAP cluster

A VE license entitles you to use the feature on all nodes in the cluster. This license is required before you can encrypt data with NVE. It is included with ONTAP One.

Prior to ONTAP One, the VE license was included with the Encryption bundle. The Encryption bundle is no longer offered, but is still valid. Although not currently required, existing customers can choose to upgrade to ONTAP One.

Before you begin

- You must be a cluster administrator to perform this task.
- You must have received the VE license key from your sales representative or have ONTAP One installed.

Steps

1. Verify that the VE license is installed.

   The VE license package name is `VE`.

2. If the license is not installed, use System Manager or the ONTAP CLI to install it.

Configure external key management

Learn about configuring external key management with ONTAP NetApp Volume Encryption

You can use one or more external key management servers to secure the keys that the cluster uses to access encrypted data. An external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP). In addition to the Onboard Key Manager, ONTAP supports several external key management servers.

```
Beginning with ONTAP 9.10.1, you can use xref:{relative_path}manage-keys-
azure-google-task.html[Azure Key Vault or Google Cloud Key Manager
Service] to protect your NVE keys for data SVMs. Beginning with ONTAP
9.11.1, you can configure multiple external key managers in a cluster. See
xref:{relative_path}configure-cluster-key-server-task.html[Configure
clustered key servers]. Beginning with ONTAP 9.12.0, you can use
link:https://docs.aws.amazon.com/kms/latest/developerguide/overview.html[A
WS' KMS^] to protect your NVE keys for data SVMs. Beginning with ONTAP
9.17.1, you can use OpenStack's xref:{relative_path}manage-keys-barbican-
task.html[Barbican KMS] to protect your NVE keys for data SVMs.
```

Manage external key managers with ONTAP System Manager

Beginning with ONTAP 9.7, you can store and manage authentication and encryption keys with the Onboard Key Manager. Beginning with ONTAP 9.13.1, you can also use external key managers to store and manage these keys.

The Onboard Key Manager stores and manages keys in a secure database that is internal to the cluster. Its scope is the cluster. An external key manager stores and manages keys outside the cluster. Its scope can be the cluster or the storage VM. One or more external key managers can be used. The following conditions apply:

- If the Onboard Key Manager is enabled, an external key manager cannot be enabled at the cluster level, but it can be enabled at the storage VM level.
- If an external key manager is enabled at the cluster level, the Onboard Key Manager cannot be enabled.

When using external key managers, you can register up to four primary key servers per storage VM and cluster. Each primary key server can be clustered with up to three secondary key servers.

Configure an external key manager

To add an external key manager for a storage VM, you should add an optional gateway when you configure the network interface for the storage VM. If the storage VM was created without the network route, you will have to create the route explicitly for the external key manager. See Create a LIF (network interface).

Steps

You can configure an external key manager starting from different locations in System Manager.

1. To configure an external key manager, perform one of the following starting steps.

Workflow	Navigation	Starting step
Configure Key Manager	**Cluster** > **Settings**	Scroll to the **Security** section. Under **Encryption**, select . Select **External Key Manager**.
Add local tier	**Storage** > **Tiers**	Select **+ Add Local Tier**. Check the check box labeled "Configure Key Manager". Select **External Key Manager**.
Prepare storage	**Dashboard**	In the **Capacity** section, select **Prepare Storage**. Then, select "Configure Key Manager". Select **External Key Manager**.
Configure encryption (key manager at storage VM scope only)	**Storage** > **Storage VMs**	Select the storage VM. Select the **Settings** tab. In the **Encryption** section under **Security**, select .

2. To add a primary key server, select + Add , and complete the **IP Address or Host Name** and **Port** fields.
3. Existing installed certificates are listed in the **KMIP Server CA Certificates** and **KMIP Client Certificate** fields. You can perform any of the following actions:
   - Select to select installed certificates that you want to map to the key manager. (Multiple service CA certificates can be selected, but only one client certificate can be selected.)
   - Select **Add New Certificate** to add a certificate that has not already been installed and map it to the external key manager.
   - Select next to the certificate name to delete installed certificates that you do not want to map to the external key manager.
4. To add a secondary key server, select **Add** in the **Secondary Key Servers** column, and provide its details.

5. Select **Save** to complete the configuration.

Edit an existing external key manager

If you have already configured an external key manager, you can modify its settings.

Steps

1. To edit the configuration of an external key manager, perform one of the following starting steps.

Scope	Navigation	Starting step
Cluster scope external key manager	**Cluster** > **Settings**	Scroll to the **Security** section. Under **Encryption**, select ⋮, then select **Edit External Key Manager**.
Storage VM scope external key manager	**Storage** > **Storage VMs**	Select the storage VM. Select the **Settings** tab. In the **Encryption** section under **Security**, select ⋮, then select **Edit External Key Manager**.

2. Existing key servers are listed in the **Key Servers** table. You can perform the following operations:
   - Add a new key server by selecting + Add.
   - Delete a key server by selecting ⋮ at the end of the table cell that contains the name of the key server. The secondary key servers associated with that primary key server are also removed from the configuration.

Delete an external key manager

An external key manager can be deleted if the volumes are unencrypted.

Steps

1. To delete an external key manager, perform one of the following steps.

Scope	Navigation	Starting step
Cluster scope external key manager	**Cluster** > **Settings**	Scroll to the **Security** section. Under **Encryption**, select select ⋮, then select **Delete External Key Manager**.
Storage VM scope external key manager	**Storage** > **Storage VMs**	Select the storage VM. Select the **Settings** tab. In the **Encryption** section under **Security**, select ⋮, then select **Delete External Key Manager**.

Migrate keys among key managers

When multiple key managers are enabled on a cluster, keys must be migrated from one key manager to another. This process is completed automatically with System Manager.

- If the Onboard Key Manager or an external key manager is enabled at a cluster level, and some volumes are encrypted, then when you configure an external key manager at the storage VM level, the keys must be migrated from the Onboard Key Manager or external key manager at the cluster level to the external key manager at the storage VM level. This process is completed automatically by System Manager.

* If volumes were created without encryption on a storage VM, then keys do not need to be migrated.

Install SSL certificates on the ONTAP cluster

The cluster and KMIP server use KMIP SSL certificates to verify each other's identity and establish an SSL connection. Before configuring the SSL connection with the KMIP server, you must install the KMIP client SSL certificates for the cluster, and the SSL public certificate for the root certificate authority (CA) of the KMIP server.

About this task

In an HA pair, both nodes must use the same public and private KMIP SSL certificates. If you connect multiple HA pairs to the same KMIP server, all nodes in the HA pairs must use the same public and private KMIP SSL certificates.

Before you begin

* The time must be synchronized on the server creating the certificates, the KMIP server, and the cluster.
* You must have obtained the public SSL KMIP client certificate for the cluster.
* You must have obtained the private key associated with the SSL KMIP client certificate for the cluster.
* The SSL KMIP client certificate must not be password-protected.
* You must have obtained the SSL public certificate for the root certificate authority (CA) of the KMIP server.
* In a MetroCluster environment, you must install the same KMIP SSL certificates on both clusters.

> You can install the client and server certificates on the KMIP server before or after installing the certificates on the cluster.

Steps

1. Install the SSL KMIP client certificates for the cluster:

   ```
   security certificate install -vserver admin_svm_name -type client
   ```

   You are prompted to enter the SSL KMIP public and private certificates.

   ```
   cluster1::> security certificate install -vserver cluster1 -type client
   ```

2. Install the SSL public certificate for the root certificate authority (CA) of the KMIP server:

   ```
   security certificate install -vserver admin_svm_name -type server-ca
   ```

   ```
   cluster1::> security certificate install -vserver cluster1 -type server-ca
   ```

Related information

* security certificate install

Enable external key management for NVE in ONTAP 9.6 and later

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. Beginning with ONTAP 9.6, you have the option to configure a separate external key manager to secure the keys that a data SVM uses to access encrypted data.

Beginning with ONTAP 9.11.1, you can add up to 3 secondary key servers per primary key server to create a clustered key server. For more information, see Configure clustered external key servers.

About this task

You can connect up to four KMIP servers to a cluster or SVM. A minimum of two servers is recommended for redundancy and disaster recovery.

The scope of external key management determines whether key management servers secure all the SVMs in the cluster or selected SVMs only:

- You can use a *cluster scope* to configure external key management for all the SVMs in the cluster. The cluster administrator has access to every key stored on the servers.
- Beginning with ONTAP 9.6, you can use an *SVM scope* to configure external key management for a data SVM in the cluster. That's best for multitenant environments in which each tenant uses a different SVM (or set of SVMs) to serve data. Only the SVM administrator for a given tenant has access to the keys for that tenant.
- For multitenant environments, install a license for *MT_EK_MGMT* by using the following command:

  ```
  system license add -license-code <MT_EK_MGMT license code>
  ```

  Learn more about `system license add` in the ONTAP command reference.

You can use both scopes in the same cluster. If key management servers have been configured for an SVM, ONTAP uses only those servers to secure keys. Otherwise, ONTAP secures keys with the key management servers configured for the cluster.

You can configure onboard key management at the cluster scope and external key management at the SVM scope. You can use the `security key-manager key migrate` command to migrate keys from onboard key management at the cluster scope to external key managers at the SVM scope.

Learn more about `security key-manager key migrate` in the ONTAP command reference.

Before you begin

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster or SVM administrator to perform this task.
- If you want to enable external key management for a MetroCluster environment, MetroCluster must be fully configured before enabling external key management.
- In a MetroCluster environment, you must install the same KMIP SSL certificate on both clusters.

Steps

1. Configure key manager connectivity for the cluster:

   ```
   security key-manager external enable -vserver admin_SVM -key-servers
   host_name|IP_address:port,… -client-cert client_certificate -server-ca-cert
   server_CA_certificates
   ```

- The `security key-manager external enable` command replaces the `security key-manager setup` command. If you run the command at the cluster login prompt, *`admin_SVM`* defaults to the admin SVM of the current cluster. You must be the cluster administrator to configure cluster scope. You can run the `security key-manager external modify` command to change the external key management configuration.
- In a MetroCluster environment, if you are configuring external key management for the admin SVM, you must repeat the `security key-manager external enable` command on the partner cluster.

The following command enables external key management for `cluster1` with three external key servers. The first key server is specified using its hostname and port, the second is specified using an IP address and the default port, and the third is specified using an IPv6 address and port:

```
cluster1::> security key-manager external enable -vserver cluster1 -key
-servers
ks1.local:15696,10.0.0.10,[fd20:8b1e:b255:814e:32bd:f35c:832c:5a09]:1234
-client-cert AdminVserverClientCert -server-ca-certs
AdminVserverServerCaCert
```

2. Configure a key manager an SVM:

`security key-manager external enable -vserver SVM -key-servers host_name|IP_address:port,… -client-cert client_certificate -server-ca-cert server_CA_certificates`

- If you run the command at the SVM login prompt, `SVM` defaults to the current SVM. You must be a cluster or SVM administrator to configure SVM scope. You can run the `security key-manager external modify` command to change the external key management configuration.
- In a MetroCluster environment, if you are configuring external key management for a data SVM, you do not have to repeat the `security key-manager external enable` command on the partner cluster.

The following command enables external key management for `svm1` with a single key server listening on the default port 5696:

```
svm11::> security key-manager external enable -vserver svm1 -key-servers
keyserver.svm1.com -client-cert SVM1ClientCert -server-ca-certs
SVM1ServerCaCert
```

3. Repeat the last step for any additional SVMs.

> You can also use the `security key-manager external add-servers` command to configure additional SVMs. The `security key-manager external add-servers` command replaces the `security key-manager add` command.
> Learn more about `security key-manager external add-servers` in the ONTAP command reference.

4. Verify that all configured KMIP servers are connected:

   `security key-manager external show-status -node node_name`

   > The `security key-manager external show-status` command replaces the `security key-manager show -status` command.
   > Learn more about `security key-manager external show-status` in the ONTAP command reference.

```
cluster1::> security key-manager external show-status

Node  Vserver  Key Server                                     Status
----  -------  ---------------------------------------

               fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234   available
               ks1.local:15696                                available

8 entries were displayed.
```

5. Optionally, convert plain text volumes to encrypted volumes.

   `volume encryption conversion start`

   An external key manager must be fully configured before you convert the volumes. In a MetroCluster environment, an external key manager must be configured on both sites.

Related information

- security key-manager setup

Enable external key management for NVE in ONTAP 9.5 and earlier

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

About this task

ONTAP configures KMIP server connectivity for all nodes in the cluster.

Before you begin

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.
- In a MetroCluster environment, you must install the same KMIP SSL certificate on both clusters.

Steps

1. Configure key manager connectivity for cluster nodes:

   `security key-manager setup`

   The key manager setup starts.

   > In a MetroCluster environment, you must run this command on both clusters. Learn more about `security key-manager setup` in the ONTAP command reference.

2. Enter the appropriate response at each prompt.
3. Add a KMIP server:

   `security key-manager add -address key_management_server_ipaddress`

   ```
   cluster1::> security key-manager add -address 20.1.1.1
   ```

   > In a MetroCluster environment, you must run this command on both clusters.

4. Add an additional KMIP server for redundancy:

   `security key-manager add -address key_management_server_ipaddress`

   ```
   cluster1::> security key-manager add -address 20.1.1.2
   ```

   > In a MetroCluster environment, you must run this command on both clusters.

5. Verify that all configured KMIP servers are connected:

   `security key-manager show -status`

Learn more about the commands described in this procedure in the ONTAP command reference.

```
cluster1::> security key-manager show -status

Node              Port      Registered Key Manager  Status
--------------    ----      ----------------------  ---------------
cluster1-01       5696      20.1.1.1                available
cluster1-01       5696      20.1.1.2                available
cluster1-02       5696      20.1.1.1                available
cluster1-02       5696      20.1.1.2                available
```

6. Optionally, convert plain text volumes to encrypted volumes.

   `volume encryption conversion start`

   An external key manager must be fully configured before you convert the volumes. In a MetroCluster environment, an external key manager must be configured on both sites.

Manage NVE keys for ONTAP data SVMs with a cloud provider

Beginning with ONTAP 9.10.1, you can use Azure Key Vault (AKV) and Google Cloud Platform's Key Management Service (Cloud KMS) to protect your ONTAP encryption keys in a cloud-hosted application. Beginning with ONTAP 9.12.0, you can also protect NVE keys with AWS' KMS.

AWS KMS, AKV and Cloud KMS can be used to protect NetApp Volume Encryption (NVE) keys only for data SVMs.

About this task

Key management with a cloud provider can be enabled with the CLI or the ONTAP REST API.

When using a cloud provider to protect your keys, be aware that by default a data SVM LIF is used to communicate with the cloud key management endpoint. A node management network is used to communicate with the cloud provider's authentication services (login.microsoftonline.com for Azure; oauth2.googleapis.com for Cloud KMS). If the cluster network is not configured correctly, the cluster will not properly use the key management service.

When utilizing a cloud provider key management service, you should be aware of the following limitations:

- Cloud-provider key management is not available for NetApp Storage Encryption (NSE) and NetApp Aggregate Encryption (NAE). External KMIPs can be used instead.
- Cloud-provider key management is not available for MetroCluster configurations.
- Cloud-provider key management can only be configured on a data SVM.

Before you begin

- You must have configured the KMS on the appropriate cloud provider.
- The ONTAP cluster's nodes must support NVE.
- You must have installed the Volume Encryption (VE) and multi-tenant Encryption Key Management

(MTEKM) licenses. These licenses are included with ONTAP One.

- You must be a cluster or SVM administrator.
- The data SVM must not include any encrypted volumes or employ a key manager. If the data SVM includes encrypted volumes, you must migrate them before configuring the KMS.

Enable external key management

Enabling external key management depends on the specific key manager you use. Choose the tab of the appropriate key manager and environment.

AWS

Before you begin

- You must create a grant for the AWS KMS key that will be used by the IAM role managing encryption. The IAM role must include a policy that allows the following operations:
  - `DescribeKey`
  - `Encrypt`
  - `Decrypt`
    +
    For more information, see AWS documentation for grants.

Enable AWS KMV on an ONTAP SVM

1. Before you begin, obtain both the access key ID and secret key from your AWS KMS.
2. Set the privilege level to advanced:
   `set -priv advanced`
3. Enable AWS KMS:
   `security key-manager external aws enable -vserver` *`svm_name`* `-region` *`AWS_region`* `-key-id` *`key_ID`* `-encryption-context` *`encryption_context`*
4. When prompted, enter the secret key.
5. Confirm the AWS KMS was configured correctly:
   `security key-manager external aws show -vserver` *`svm_name`*

   Learn more about `security key-manager external aws` in the ONTAP command reference.

Azure

Enable Azure Key Vault on an ONTAP SVM

1. Before you begin, you need to obtain the appropriate authentication credentials from your Azure account, either a client secret or certificate.
   You must also ensure all nodes in the cluster are healthy. You can check this with the command `cluster show`. Learn more about `cluster show` in the ONTAP command reference.
2. Set privileged level to advanced
   `set -priv advanced`
3. Enable AKV on the SVM
   `security key-manager external azure enable -client-id` *`client_id`* `-tenant-id` *`tenant_id`* `-name -key-id` *`key_id`* `-authentication-method {certificate|client-secret}`
   When prompted, enter either the client certificate or client secret from your Azure account.
4. Verify AKV is enabled correctly:
   `security key-manager external azure show vserver` *`svm_name`*
   If the service reachability is not OK, establish the connectivity to the AKV key management service via the data SVM LIF.

   Learn more about `security key-manager external azure` in the ONTAP command reference.

Google Cloud

Enable Cloud KMS on an ONTAP SVM

1. Before you begin, obtain the private key for the Google Cloud KMS account key file in a JSON format. This can be found in your GCP account.
   You must also ensure all nodes in the cluster are healthy. You can check this with the command `cluster show`. Learn more about `cluster show` in the ONTAP command reference.
2. Set privileged level to advanced:
   `set -priv advanced`
3. Enable Cloud KMS on the SVM
   `security key-manager external gcp enable -vserver` *`svm_name`* `-project-id` *`project_id`*`-key-ring-name` *`key_ring_name`* `-key-ring-location` *`key_ring_location`* `-key-name` *`key_name`*
   When prompted, enter the contents of the JSON file with the Service Account Private Key
4. Verify that Cloud KMS is configured with the correct parameters:
   `security key-manager external gcp show vserver` *`svm_name`*
   The status of `kms_wrapped_key_status` will be "`UNKNOWN`" if no encrypted volumes have been created.
   If the service reachability is not OK, establish the connectivity to the GCP key management service via data SVM LIF.

   Learn more about `security key-manager external gcp` in the ONTAP command reference.

If one or more encrypted volumes is already configured for a data SVM and the corresponding NVE keys are managed by the admin SVM onboard key manager, those keys should be migrated to the external key management service. To do this with the CLI, run the command:
`security key-manager key migrate -from-Vserver` *`admin_SVM`* `-to-Vserver` *`data_SVM`*
New encrypted volumes cannot be created for the tenant's data SVM until all NVE keys of the data SVM are successfully migrated.

Manage ONTAP keys with Barbican KMS

Beginning with ONTAP 9.17.1, you can use OpenStack's Barbican KMS to protect ONTAP encryption keys. Barbican KMS is a service for securely storing and accessing keys. Barbican KMS can be used to protect NetApp Volume Encryption (NVE) keys for data SVMs. Barbican relies on OpenStack Keystone, OpenStack's identity service, for authentication.

About this task

You can configure key management with Barbican KMS with the CLI or the ONTAP REST API. With the 9.17.1 release, Barbican KMS support has the following limitations:

- Barbican KMS is not supported for NetApp Storage Encryption (NSE) and NetApp Aggregate Encryption (NAE). Alternatively, you can use external KMIPs or the Onboard Key Manager (OKM) for NSE and NVE keys.
- Barbican KMS is not supported for MetroCluster configurations.
- Barbican KMS can only be configured for a data SVM. It is not available for the admin SVM.

Unless otherwise noted, administrators at the `admin` privilege level can perform the following procedures.

Before you begin

- Barbican KMS and OpenStack Keystone must be configured. The SVM you are using with Barbican must have network access to the Barbican and OpenStack Keystone servers.
- If you are using a custom Certificate Authority (CA) for the Barbican and OpenStack Keystone servers, you must install the CA certificate with `security certificate install -type server-ca -vserver <admin_svm>`.

Create and activate a Barbican KMS configuration

You can create a new Barbican KMS configuration for an SVM and activate it. An SVM can have multiple inactive Barbican KMS configurations, but only one can be active at a time.

Steps

1. Create a new inactive Barbican KMS configuration for an SVM:

```
security key-manager external barbican create-config -vserver <svm_name>
-config-name <unique_config_name> -key-id <key_id> -keystone-url
<keystone_url> -application-cred-id
<keystone_applications_credentials_id>
```

   - `-key-id` is the key identifier of the Barbican key encryption key (KEK). Enter a full URL, including `https://`.

     Some URLs include the question mark (?) character. The question mark activates the ONTAP command line active help. In order to enter a URL with a question mark, you need to first disable active help with the command `set -active-help false`. Active help can later be re-enabled with the command `set -active-help true`. Learn more in the ONTAP command reference.

   - `-keystone-url` is the URL of the OpenStack Keystone authorization host. Enter a full URL, including `https://`.
   - `-application-cred-id` is the application credentials ID.

   After entering this command, you will be prompted for the application credentials secret key. This command creates an inactive Barbican KMS configuration.

   The following example creates a new inactive Barbican KMS configuration named `config1` for the SVM `svm1`:

```
cluster1::> security key-manager external barbican create-config
-vserver svm1 -config-name config1 -keystone-url
https://172.21.76.152:5000/v3 -application-cred-id app123 -key-id
https://172.21.76.153:9311/v1/secrets/<id_value>

Enter the Application Credentials Secret for authentication with
Keystone: <key_value>
```

2. Activate the new Barbican KMS configuration:

```
security key-manager keystore enable -vserver <svm_name> -config-name
<unique_config_name> -keystore barbican
```

You can use this command to switch between Barbican KMS configurations. If there is already an active Barbican KMS configuration on the SVM, it will be made inactive and the new configuration will be activated.

3. Verify that the new Barbican KMS configuration is active:

```
security key-manager external barbican check -vserver <svm_name> -node
<node_name>
```

This command will provide the status of the active Barbican KMS configuration on the SVM or node. For example, if the SVM `svm1` on node `node1` has an active Barbican KMS configuration, the following command will return the status of that configuration:

```
cluster1::> security key-manager external barbican check -node node1

Vserver: svm1
Node: node1

Category: service_reachability
              Status: OK

Category: kms_wrapped_key_status
              Status: OK
```

Update the credentials and settings of a Barbican KMS configuration

You can view and update the current settings of an active or inactive Barbican KMS configuration.

Steps

1. View the current Barbican KMS configurations for an SVM:

```
security key-manager external barbican show -vserver <svm_name>
```

The key ID, OpenStack Keystone URL, and application credentials ID are displayed for each Barbican KMS configuration on the SVM.

2. Update the settings of a Barbican KMS configuration:

```
security key-manager external barbican update-config -vserver <svm_name>
-config-name <unique_config_name> -timeout <timeout> -verify
<true|false> -verify-host <true|false>
```

This command updates the timeout and verification settings of the specified Barbican KMS configuration. `timeout` determines the time in seconds ONTAP will wait for Barbican to respond before the connection fails. The default `timeout` is ten seconds. `verify` and `verify-host` determine if the identity and hostname respectively of Barbican host should be verified before connecting. By default, these parameters are set to `true`. The `vserver` and `config-name` parameters are required. The other parameters are optional.

3. If needed, update the credentials of an active or inactive Barbican KMS configuration:

```
security key-manager external barbican update-credentials -vserver
<svm_name> -config-name <unique_config_name> -application-cred-id
<keystone_applications_credentials_id>
```

After entering this command, you will be prompted for the new application credentials secret key.

4. If needed, restore a missing SVM key encryption key (KEK) for an active Barbican KMS configuration:

   a. Restore a missing SVM KEK with `security key-manager external barbican restore`:

   ```
   security key-manager external barbican restore -vserver <svm_name>
   ```

   This command will restore the SVM KEK for the active Barbican KMS configuration by communicating with the Barbican server.

5. If needed, rekey the SVM KEK for a Barbican KMS configuration:

   a. Set the privilege level to advanced:

   ```
   set -privilege advanced
   ```

   b. Rekey the SVM KEK with `security key-manager external barbican rekey-internal`:

```
security key-manager external barbican rekey-internal -vserver
<svm_name>
```

This command generates a new SVM KEK for the specified SVM and re-wraps the volume encryption keys with the new SVM KEK. The new SVM KEK will be protected by the active Barbican KMS configuration.

Migrate keys between Barbican KMS and the Onboard Key Manager

You can migrate keys from Barbican KMS to the Onboard Key Manager (OKM), and vice-versa. To learn more about the OKM, refer to Enable onboard key management in ONTAP 9.6 and later.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. If needed, migrate keys from Barbican KMS to the OKM:

```
security key-manager key migrate -from-vserver <svm_name> -to-vserver
<admin_svm_name>
```

`svm_name` is the name of the SVM with the Barbican KMS configuration.

3. If needed, migrate keys from the OKM to Barbican KMS:

```
security key-manager key migrate -from-vserver <admin_svm_name> -to
-vserver <svm_name>
```

Disable and delete a Barbican KMS configuration

You can disable an active Barbican KMS configuration with no encrypted volumes, and you can delete an inactive Barbican KMS configuration.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Disable an active Barbican KMS configuration:

```
security key-manager keystore disable -vserver <svm_name>
```

If NVE encrypted volumes exist on the SVM, you must decrypt them or migrate the keys before disabling the Barbican KMS configuration. Activating a new Barbican KMS configuration does not require decrypting NVE volumes or migrating keys, and will disable the current active Barbican KMS configuration.

3. Delete an inactive Barbican KMS configuration:

```
security key-manager keystore delete -vserver <svm_name> -config-name
<unique_config_name> -type barbican
```

Enable onboard key management for NVE in ONTAP 9.6 and later

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable the Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

About this task

You must run the `security key-manager onboard sync` command each time you add a node to the cluster.

If you have a MetroCluster configuration, you must run the `security key-manager onboard enable` command on the local cluster first, then run the `security key-manager onboard sync` command on the remote cluster, using the same passphrase on each. When you run the `security key-manager onboard enable` command from the local cluster and then synchronize on the remote cluster, you do not need to run the `enable` command again from the remote cluster.

Learn more about `security key-manager onboard enable` and `security key-manager onboard sync` in the ONTAP command reference.

By default, you are not required to enter the key manager passphrase when a node is rebooted. You can use the `cc-mode-enabled=yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `cc-mode-enabled=yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

When configuring ONTAP data at rest encryption, to meet the requirements for Commercial Solutions for Classified (CSfC) you must use NSE with NVE and ensure the Onboard Key Manager is enabled in Common Criteria mode. Refer to the CSfC Solution Brief for more information on CSfC.

When the Onboard Key Manager is enabled in Common Criteria mode (`cc-mode-enabled=yes`), system behavior is changed in the following ways:

- The system monitors for consecutive failed cluster passphrase attempts when operating in Common Criteria mode.

  If you fail to enter the correct cluster passphrase at boot, encrypted volumes are not mounted. To correct this, you must reboot the node and enter the correct cluster passphrase. Once booted, the system allows up to 5 consecutive attempts to correctly enter the cluster passphrase in a 24-hour period for any command that requires the cluster passphrase as a parameter. If the limit is reached (for example, you have failed to correctly enter the cluster passphrase 5 times in a row) then you must either wait for the 24-hour timeout period to elapse, or you must reboot the node, in order to reset the limit.

- System image updates use the NetApp RSA-3072 code signing certificate together with SHA-384 code signed digests to check the image integrity instead of the usual NetApp RSA-2048 code signing certificate and SHA-256 code signed digests.

  The upgrade command verifies that the image contents have not been altered or corrupted by checking various digital signatures. The image update process proceeds to the next step if validation succeeds; otherwise, the image update fails. Learn more about `cluster image` in the ONTAP command reference.

The Onboard Key Manager stores keys in volatile memory. Volatile memory contents are cleared when the system is rebooted or halted. Under normal operating conditions, volatile memory contents will be cleared within 30s when a system is halted.

Before you begin

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure the Onboard Key Manager.

Steps

1. Start the key manager setup:

   ```
   security key-manager onboard enable -cc-mode-enabled yes|no
   ```

   Set `cc-mode-enabled=yes` to require that users enter the key manager passphrase after a reboot. For NVE, if you set `cc-mode-enabled=yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. The `- cc-mode-enabled` option is not supported in MetroCluster configurations. The `security key-manager onboard enable` command replaces the `security key-manager setup` command.

   The following example starts the key manager setup command on cluster1 without requiring that the passphrase be entered after every reboot:

```
cluster1::> security key-manager onboard enable

Enter the cluster-wide passphrase for onboard key management in Vserver
"cluster1"::    <32..256 ASCII characters long text>
Reenter the cluster-wide passphrase:    <32..256 ASCII characters long
text>
```

2. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

   > If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

3. At the passphrase confirmation prompt, reenter the passphrase.
4. Verify that the authentication keys have been created:

   `security key-manager key query -key-type NSE-AK`

   > The `security key-manager key query` command replaces the `security key-manager query key` command.

   The following example verifies that authentication keys have been created for `cluster1`:

```
cluster1::> security key-manager key query -key-type NSE-AK
               Node: node1
            Vserver: cluster1
        Key Manager: onboard
   Key Manager Type: OKM
 Key Manager Policy: -

 Key Tag                              Key Type Encryption   Restored

------------------------------------ -------- ------------ --------

node1                                NSE-AK   AES-256      true

    Key ID: <id_value>

node1                                NSE-AK   AES-256      true

    Key ID: <id_value>

2 entries were displayed.
```

Learn more about `security key-manager key query` in the ONTAP command reference.

5. Optionally, convert plain text volumes to encrypted volumes.

   ```
   volume encryption conversion start
   ```

   The Onboard Key Manager must be fully configured before you convert the volumes. In a MetroCluster environment, the Onboard Key Manager must be configured on both sites.

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

Whenever you configure the Onboard Key Manager passphrase, you should also back up the information manually to a secure location outside the storage system for use in case of a disaster. See Back up onboard key management information manually.

Related information

- security key-manager setup

Enable onboard key management for NVE in ONTAP 9.5 and earlier

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

About this task

You must run the `security key-manager setup` command each time you add a node to the cluster.

If you have a MetroCluster configuration, review these guidelines:

- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

> After a failed passphrase attempt, you must reboot the node again.

Before you begin

- If you are using NSE or NVE with an external key management (KMIP) server, you must have deleted the external key manager database.

  Transitioning to onboard key management from external key management

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure the Onboard Key Manager.

Steps

1. Start the key manager setup:

   `security key-manager setup -enable-cc-mode yes|no`

   > Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the key manager passphrase after a reboot. For NVE, if you set `-enable-cc -mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted.

   The following example starts setting up the key manager on cluster1 without requiring that the passphrase be entered after every reboot:

   ```
   cluster1::> security key-manager setup
   Welcome to the key manager setup wizard, which will lead you through
   the steps to add boot information.

   ...

   Would you like to use onboard key-management? {yes, no} [yes]:
   Enter the cluster-wide passphrase:    <32..256 ASCII characters long
   text>
   Reenter the cluster-wide passphrase:    <32..256 ASCII characters long
   text>
   ```

2. Enter `yes` at the prompt to configure onboard key management.
3. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

   > If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

4. At the passphrase confirmation prompt, reenter the passphrase.
5. Verify that keys are configured for all nodes:

   `security key-manager key show`

```
cluster1::> security key-manager key show

Node: node1
Key Store: onboard
Key ID                                                             Used By
-----------------------------------------------------------------
--------
<id_value> NSE-AK
<id_value> NSE-AK

Node: node2
Key Store: onboard
Key ID                                                             Used By
-----------------------------------------------------------------
--------
<id_value> NSE-AK
<id_value> NSE-AK
```

Learn more about `security key-manager key show` in the ONTAP command reference.

6. Optionally, convert plain text volumes to encrypted volumes.

   `volume encryption conversion start`

   The Onboard Key Manager must be fully configured before you convert the volumes. In a MetroCluster environment, the Onboard Key Manager must be configured on both sites.

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

Whenever you configure the Onboard Key Manager passphrase, you should also back up the information manually to a secure location outside the storage system for use in case of a disaster. See Back up onboard key management information manually.

- security key-manager setup

Enable onboard key management in newly added ONTAP nodes

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

> For ONTAP 9.5 and earlier, you must run the `security key-manager setup` command each time you add a node to the cluster.
>
> For ONTAP 9.6 and later, you must run the `security key-manager sync` command each time you add a node to the cluster.
>
> If you add a node to a cluster that has onboard key management configured, you will run this command to refresh the missing keys.

If you have a MetroCluster configuration, review these guidelines:

- Beginning with ONTAP 9.6, you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.

  Learn more about `security key-manager onboard enable` and `security key-manager onboard sync` in the ONTAP command reference.

- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

> After a failed passphrase attempt, you must reboot the node again.

- security key-manager setup

Encrypt volume data with NVE or NAE

Learn about encrypting ONTAP volume data with NVE

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default when you have the VE license and onboard or external key management. For ONTAP 9.6 and earlier, you can enable encryption on a new volume or on an existing volume. You must have installed the VE license and enabled key management before you can enable volume encryption. NVE is FIPS-140-2 level 1 compliant.

Enable aggregate-level encryption with VE license in ONTAP

Beginning with ONTAP 9.7, newly created aggregates and volumes are encrypted by default when you have the VE license and onboard or external key management. Beginning with ONTAP 9.6, you can use aggregate-level encryption to assign keys to the containing aggregate for the volumes to be encrypted.

About this task

You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication. Aggregate-level deduplication is otherwise not supported by NVE.

An aggregate enabled for aggregate-level encryption is called an *NAE aggregate* (for NetApp Aggregate Encryption). All volumes in an NAE aggregate must be encrypted with NAE or NVE encryption. With aggregate-level encryption, volumes you create in the aggregate are encrypted with NAE encryption by default. You can override the default to use NVE encryption instead.

Plain text volumes are not supported in NAE aggregates.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Enable or disable aggregate-level encryption:

To…	Use this command…
Create an NAE aggregate with ONTAP 9.7 or later	`storage aggregate create -aggregate` *`aggregate_name`* `-node` *`node_name`*
Create an NAE aggregate with ONTAP 9.6	`storage aggregate create -aggregate` *`aggregate_name`* `-node` *`node_name`* `-encrypt-with -aggr-key true`
Convert a non-NAE aggregate to an NAE aggregate	`storage aggregate modify -aggregate` *`aggregate_name`* `-node` *`node_name`* `-encrypt-with -aggr-key true`
Convert an NAE aggregate to a non-NAE aggregate	`storage aggregate modify -aggregate` *`aggregate_name`* `-node` *`node_name`* `-encrypt-with -aggr-key false`

Learn more about `storage aggregate modify` in the ONTAP command reference.

The following command enables aggregate-level encryption on `aggr1`:

- ONTAP 9.7 or later:

```
cluster1::> storage aggregate create -aggregate aggr1
```

- ONTAP 9.6 or earlier:

```
cluster1::> storage aggregate create -aggregate aggr1 -encrypt-with
-aggr-key true
```

Learn more about `storage aggregate create` in the ONTAP command reference.

2. Verify that the aggregate is enabled for encryption:

   `storage aggregate show -fields encrypt-with-aggr-key`

   The following command verifies that `aggr1` is enabled for encryption:

```
cluster1::> storage aggregate show -fields encrypt-with-aggr-key
aggregate            encrypt-aggr-key
-------------------- ----------------
aggr0_vsim4          false
aggr1                true
2 entries were displayed.
```

   Learn more about `storage aggregate show` in the ONTAP command reference.

After you finish

Run the `volume create` command to create the encrypted volumes.

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

Enable encryption on a new volume in ONTAP

You can use the `volume create` command to enable encryption on a new volume.

About this task

You can encrypt volumes using NetApp Volume Encryption (NVE) and, beginning with ONTAP 9.6, NetApp Aggregate Encryption (NAE). To learn more about NAE and NVE, refer to the volume encryption overview.

Learn more about the commands described in this procedure in the ONTAP command reference.

The procedure to enable encryption on a new volume in ONTAP varies based on the version of ONTAP you are using and your specific configuration:

- Beginning with ONTAP 9.4, if you enable `cc-mode` when you set up the Onboard Key Manager, volumes you create with the `volume create` command are automatically encrypted, whether or not you specify `-encrypt true`.
- In ONTAP 9.6 and earlier releases, you must use `-encrypt true` with `volume create` commands to enable encryption (provided you did not enable `cc-mode`).
- If you want to create an NAE volume in ONTAP 9.6, you must enable NAE at the aggregate level. Refer to Enable aggregate-level encryption with the VE license for more details on this task.

- Beginning with ONTAP 9.7, newly created volumes are encrypted by default when you have the VE license and onboard or external key management. By default, new volumes created in an NAE aggregate will be of type NAE rather than NVE.
  - In ONTAP 9.7 and later releases, if you add `-encrypt true` to the `volume create` command to create a volume in an NAE aggregate, the volume will have NVE encryption instead of NAE. All volumes in an NAE aggregate must be encrypted with either NVE or NAE.

> ⓘ Plaintext volumes are not supported in NAE aggregates.

Steps

1. Create a new volume and specify whether encryption is enabled on the volume. If the new volume is in an NAE aggregate, by default the volume will be an NAE volume:

To create…	Use this command…
An NAE volume	`volume create -vserver` *SVM_name* `-volume` *volume_name* `-aggregate` *aggregate_name*
An NVE volume	`volume create -vserver` *SVM_name* `-volume` *volume_name* `-aggregate` *aggregate_name* `-encrypt true` + ⓘ In ONTAP 9.6 and earlier where NAE is not supported, `-encrypt true` specifies that the volume should be encrypted with NVE. In ONTAP 9.7 and later where volumes are created in NAE aggregates, `-encrypt true` overrides the default encryption type of NAE to create an NVE volume instead.
A plain text volume	`volume create -vserver` *SVM_name* `-volume` *volume_name* `-aggregate` *aggregate_name* `-encrypt false`

   Learn more about `volume create` in the ONTAP command reference.

2. Verify that volumes are enabled for encryption:

   ```
   volume show -is-encrypted true
   ```

   Learn more about `volume show` in the ONTAP command reference.

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically "pushes" an encryption key to the server when you encrypt a volume.

Enable NAE or NVE on an existing ONTAP volume

You can use either the `volume move start` or the `volume encryption conversion start` command to enable encryption on an existing volume.

About this task

You can use the `volume encryption conversion start` command to enable encryption of an existing volume "in place," without having to move the volume to a different location. Alternatively, you can use the `volume move start` command.

Enable encryption on an existing volume with the volume encryption conversion start command

You can use the `volume encryption conversion start` command to enable encryption of an existing volume "in place," without having to move the volume to a different location.

After you start a conversion operation, it must be completed. If you encounter a performance issue during the operation, you can run the `volume encryption conversion pause` command to pause the operation, and the `volume encryption conversion resume` command to resume the operation.

> You cannot use `volume encryption conversion start` to convert a SnapLock volume.

Steps

1. Enable encryption on an existing volume:

   `volume encryption conversion start -vserver SVM_name -volume volume_name`

   Learn more about `volume encryption conversion start` in the ONTAP command reference.

   The following command enables encryption on existing volume `vol1`:

   ```
   cluster1::> volume encryption conversion start -vserver vs1 -volume vol1
   ```

   The system creates an encryption key for the volume. The data on the volume is encrypted.

2. Verify the status of the conversion operation:

   `volume encryption conversion show`

   Learn more about `volume encryption conversion show` in the ONTAP command reference.

   The following command displays the status of the conversion operation:

   ```
   cluster1::> volume encryption conversion show

   Vserver   Volume   Start Time           Status
   -------   ------   ------------------   ---------------------------
   vs1       vol1     9/18/2017 17:51:41   Phase 2 of 2 is in progress.
   ```

3. When the conversion operation is completed, verify that the volume is enabled for encryption:

   `volume show -is-encrypted true`

   Learn more about `volume show` in the ONTAP command reference.

   The following command displays the encrypted volumes on `cluster1`:

```
cluster1::> volume show -is-encrypted true

Vserver  Volume  Aggregate  State  Type  Size  Available  Used
-------  ------  ---------  -----  ----  -----  ---------  ----
vs1      vol1    aggr2     online    RW  200GB    160.0GB  20%
```

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically "pushes" an encryption key to the server when you encrypt a volume.

Enable encryption on an existing volume with the volume move start command

You can use the `volume move start` command to enable encryption by moving an existing volume. You can use the same aggregate or a different aggregate.

About this task

- Beginning with ONTAP 9.8, you can use `volume move start` to enable encryption on a SnapLock or FlexGroup volume.
- Beginning with ONTAP 9.4, if you enable "cc-mode" when you set up the Onboard Key Manager, volumes you create with the `volume move start` command are automatically encrypted. You need not specify `-encrypt-destination true`.
- Beginning with ONTAP 9.6, you can use aggregate-level encryption to assign keys to the containing aggregate for the volumes to be moved. A volume encrypted with a unique key is called an *NVE volume* (meaning it uses NetApp Volume Encryption). A volume encrypted with an aggregate-level key is called an *NAE volume* (for NetApp Aggregate Encryption). Plaintext volumes are not supported in NAE aggregates.
- Beginning with ONTAP 9.14.1, you can encrypt an SVM root volume with NVE. For more information, see Configure NetApp Volume Encryption on an SVM root volume.

Before you begin

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

Delegating authority to run the volume move command

Steps

1. Move an existing volume and specify whether encryption is enabled on the volume:

To convert…	Use this command…
A plaintext volume to an NVE volume	`volume move start -vserver` *`SVM_name`* `-volume` *`volume_name`* `-destination-aggregate` *`aggregate_name`* `-encrypt-destination true`
An NVE or plaintext volume to an NAE volume (assuming aggregate-level encryption is enabled on the destination)	`volume move start -vserver` *`SVM_name`* `-volume` *`volume_name`* `-destination-aggregate` *`aggregate_name`* `-encrypt-with-aggr-key true`

An NAE volume to an NVE volume	`volume move start -vserver` *`SVM_name`* `-volume` *`volume_name`* `-destination-aggregate` *`aggregate_name`* `-encrypt-with-aggr-key false`
An NAE volume to a plaintext volume	`volume move start -vserver` *`SVM_name`* `-volume` *`volume_name`* `-destination-aggregate` *`aggregate_name`* `-encrypt-destination false -encrypt-with-aggr-key false`
An NVE volume to a plaintext volume	`volume move start -vserver` *`SVM_name`* `-volume` *`volume_name`* `-destination-aggregate` *`aggregate_name`* `-encrypt-destination false`

Learn more about `volume move start` in the ONTAP command reference.

The following command converts a plaintext volume named `vol1` to an NVE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination
-aggregate aggr2 -encrypt-destination true
```

Assuming aggregate-level encryption is enabled on the destination, the following command converts an NVE or plaintext volume named `vol1` to an NAE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination
-aggregate aggr2 -encrypt-with-aggr-key true
```

The following command converts an NAE volume named `vol2` to an NVE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination
-aggregate aggr2 -encrypt-with-aggr-key false
```

The following command converts an NAE volume named `vol2` to a plaintext volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination
-aggregate aggr2 -encrypt-destination false -encrypt-with-aggr-key false
```

The following command converts an NVE volume named `vol2` to a plaintext volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination
-aggregate aggr2 -encrypt-destination false
```

2. View the encryption type of cluster volumes:

   `volume show -fields encryption-type none|volume|aggregate`

   The `encryption-type` field is available in ONTAP 9.6 and later.

   Learn more about `volume show` in the ONTAP command reference.

   The following command displays the encryption type of volumes in `cluster2`:

```
cluster2::> volume show -fields encryption-type

vserver  volume  encryption-type
-------  ------  ---------------
vs1      vol1    none
vs2      vol2    volume
vs3      vol3    aggregate
```

3. Verify that volumes are enabled for encryption:

   `volume show -is-encrypted true`

   Learn more about `volume show` in the ONTAP command reference.

   The following command displays the encrypted volumes on `cluster2`:

```
cluster2::> volume show -is-encrypted true

Vserver  Volume  Aggregate  State  Type  Size  Available  Used
-------  ------  ---------  -----  ----  -----  ---------  ----
vs1      vol1    aggr2     online    RW  200GB    160.0GB  20%
```

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically pushes an encryption key to the server when you encrypt a volume.

Configure NVE on an ONTAP SVM root volume

Beginning with ONTAP 9.14.1, you can enable NetApp Volume Encryption (NVE) on a storage VM (SVM) root volume. With NVE, the root volume is encrypted with a unique key, enabling greater security on the SVM.

About this task

NVE on an SVM root volume can only be enabled after the SVM has been created.

Before you begin

- The SVM root volume must not be on an aggregate encrypted with NetApp Aggregate Encryption (NAE).

- You must have enabled encryption with the Onboard Key Manager or an external key manager.
- You must be running ONTAP 9.14.1 or later.
- To migrate an SVM containing a root volume encrypted with NVE, you must convert the SVM root volume to a plain text volume after the migration completes then re-encrypt the SVM root volume.
  - If the destination aggregate of the SVM migration uses NAE, the root volume inherits NAE by default.
- If the SVM is in an SVM disaster recovery relationship:
  - Encryption settings on a mirrored SVM are not copied to the destination. If you enable NVE on the source or destination, you must separately enable NVE on the mirrored SVM root volume.
  - If all aggregates in the destination cluster use NAE, the SVM root volume will use NAE.

Steps

You can enable NVE on an SVM root volume with the ONTAP CLI or System Manager.

CLI

You can enable NVE on the SVM root volume in-place or by moving the volume between aggregates.

Encrypt the root volume in place

1. Convert the root volume to an encrypted volume:

   ```
   volume encryption conversion start -vserver svm_name -volume volume
   ```

2. Confirm the encryption succeeded. The `volume show -encryption-type volume` displays a list of all volumes using NVE.

Encrypt the SVM root volume by moving it

1. Initiate a volume move:

   ```
   volume move start -vserver svm_name -volume volume -destination-aggregate
   aggregate -encrypt-with-aggr-key false -encrypt-destination true
   ```

   Learn more about `volume move` in the ONTAP command reference.

2. Confirm the `volume move` operation succeeded with the `volume move show` command. The `volume show -encryption-type volume` displays a list of all volumes using NVE.

System Manager

1. Navigate to **Storage** > **Volumes**.
2. Next to the name of the SVM root volume you want to encrypt, select ⋮ then **Edit**.
3. Under the **Storage and Optimization** heading, select **Enable encryption**.
4. Select **Save**.

Configure NVE on an ONTAP node root volume

Beginning with ONTAP 9.8, you can use NetApp Volume Encryption to protect the root volume of your node.

About this task

This procedure applies to the node root volume. It does not apply to SVM root volumes. SVM root volumes can be protected through aggregate-level encryption and, beginning with ONTAP 9.14.1, NVE.

Once root volume encryption begins, it must complete. You cannot pause the operation. Once encryption is complete, you cannot assign a new key to the root volume and you cannot perform a secure-purge operation.

Before you begin

- Your system must be using an HA configuration.
- Your node root volume must already be created.
- Your system must have an onboard key manager or an external key management server using the Key Management Interoperability Protocol (KMIP).

Steps

1. Encrypt the root volume:

   `volume encryption conversion start -vserver` *`SVM_name`* `-volume` *`root_vol_name`*

2. Verify the status of the conversion operation:

   `volume encryption conversion show`

3. When the conversion operation is complete, verify that the volume is encrypted:

   `volume show -fields`

   The following shows example output for an encrypted volume.

```
::> volume show -vserver xyz  -volume vol0 -fields is-encrypted
vserver    volume is-encrypted
---------- ------ ------------
xyz        vol0   true
```

Configure NetApp hardware-based encryption

Learn about ONTAP hardware-based encryption

NetApp hardware-based encryption supports full-disk encryption (FDE) of data as it is written. The data cannot be read without an encryption key stored on the firmware. The encryption key, in turn, is accessible only to an authenticated node.

Understanding NetApp hardware-based encryption

A node authenticates itself to a self-encrypting drive using an authentication key retrieved from an external key management server or Onboard Key Manager:

- The external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP). It is a best practice to configure external key management servers on a different storage system from your data.

- The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data.

You can use NetApp Volume Encryption with hardware-based encryption to “double encrypt” data on self-encrypting drives.

When self-encrypting drives are enabled, the core dump is also encrypted.

> If an HA pair is using encrypting SAS or NVMe drives (SED, NSE, FIPS), you must follow the instructions in the topic Returning a FIPS drive or SED to unprotected mode for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

Supported self-encrypting drive types

Two types of self-encrypting drives are supported:

- Self-encrypting FIPS-certified SAS or NVMe drives are supported on all FAS and AFF systems. These drives, called *FIPS drives,* conform to the requirements of Federal Information Processing Standard Publication 140-2, level 2. The certified capabilities enable protections in addition to encryption, such as preventing denial-of-service attacks on the drive. FIPS drives cannot be mixed with other types of drives on the same node or HA pair.
- Beginning with ONTAP 9.6, self-encrypting NVMe drives that have not undergone FIPS testing are supported on AFF A800, A320, and later systems. These drives, called *SEDs*, offer the same encryption capabilities as FIPS drives, but can be mixed with non-encrypting drives on the same node or HA pair.
- All FIPS validated drives use a firmware cryptographic module that has been through FIPS validation. The FIPS drive cryptographic module does not use any keys that are generated outside of the drive (the authentication passphrase that is input to the drive is used by the drive’s firmware cryptographic module to obtain a key encryption key).

> Non-encrypting drives are drives that are not SEDs or FIPS drives.

> If you are using NSE on a system with a Flash Cache module, you should also enable NVE or NAE. NSE does not encrypt data that resides on the Flash Cache module.

When to use external key management

Although it is less expensive and typically more convenient to use the onboard key manager, you should use external key management if any of the following are true:

- Your organization’s policy requires a key management solution that uses a FIPS 140-2 Level 2 (or higher) cryptographic module.
- You need a multi-cluster solution, with centralized management of encryption keys.
- Your business requires the added security of storing authentication keys on a system or in a location different from the data.

Support details

The following table shows important hardware encryption support details. See the Interoperability Matrix for the latest information about supported KMIP servers, storage systems, and disk shelves.

Resource or feature	Support details
Non-homogeneous disk sets	• FIPS drives cannot be mixed with other types of drives on the same node or HA pair. Conforming HA pairs can coexist with non-conforming HA pairs in the same cluster. • SEDs can be mixed with non-encrypting drives on the same node or HA pair.
Drive type	• FIPS drives can be SAS or NVMe drives. • SEDs must be NVMe drives.
10 Gb network interfaces	Beginning with ONTAP 9.3, KMIP key management configurations support 10 Gb network interfaces for communications with external key management servers.
Ports for communication with the key management server	Beginning with ONTAP 9.3, you can use any storage controller port for communication with the key management server. Otherwise, you should use port e0M for communication with key management servers. Depending on the storage controller model, certain network interfaces might not be available during the boot process for communication with key management servers.
MetroCluster (MCC)	• NVMe drives support MCC. • SAS drives do not support MCC.

Hardware-based encryption workflow

You must configure key management services before the cluster can authenticate itself to the self-encrypting drive. You can use an external key management server or an onboard key manager.

- NetApp Hardware Universe
- NetApp Volume Encryption and NetApp Aggregate Encryption

Configure external key management

Learn about configuring ONTAP external key management

You can use one or more external key management servers to secure the keys that the cluster uses to access encrypted data. An external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP).

NetApp Volume Encryption (NVE) can be implemented with Onboard Key Manager. In ONTAP 9.3 and later, NVE can be implemented with external key management (KMIP) and Onboard Key Manager. Beginning with ONTAP 9.11.1, you can configure multiple external key managers in a cluster. See Configure clustered key servers.

Install SSL certificates on the ONTAP cluster

The cluster and KMIP server use KMIP SSL certificates to verify each other's identity and establish an SSL connection. Before configuring the SSL connection with the KMIP server, you must install the KMIP client SSL certificates for the cluster, and the SSL public certificate for the root certificate authority (CA) of the KMIP server.

About this task

In an HA pair, both nodes must use the same public and private KMIP SSL certificates. If you connect multiple HA pairs to the same KMIP server, all nodes in the HA pairs must use the same public and private KMIP SSL certificates.

Before you begin

- The time must be synchronized on the server creating the certificates, the KMIP server, and the cluster.
- You must have obtained the public SSL KMIP client certificate for the cluster.
- You must have obtained the private key associated with the SSL KMIP client certificate for the cluster.
- The SSL KMIP client certificate must not be password-protected.
- You must have obtained the SSL public certificate for the root certificate authority (CA) of the KMIP server.
- In a MetroCluster environment, you must install the same KMIP SSL certificates on both clusters.

> ⓘ You can install the client and server certificates on the KMIP server before or after installing the certificates on the cluster.

Steps

1. Install the SSL KMIP client certificates for the cluster:

   ```
   security certificate install -vserver admin_svm_name -type client
   ```

   You are prompted to enter the SSL KMIP public and private certificates.

   ```
   cluster1::> security certificate install -vserver cluster1 -type client
   ```

2. Install the SSL public certificate for the root certificate authority (CA) of the KMIP server:

   ```
   security certificate install -vserver admin_svm_name -type server-ca
   ```

   ```
   cluster1::> security certificate install -vserver cluster1 -type server-ca
   ```

Related information

- security certificate install

Enable external key management for hardware-based encryption in ONTAP 9.6 and later

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

Beginning with ONTAP 9.11.1, you can add up to 3 secondary key servers per primary key server to create a clustered key server. For more information, see Configure clustered external key servers.

Before you begin

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.
- In a MetroCluster environment, you must install the same KMIP SSL certificate on both clusters.

Steps

1. Configure key manager connectivity for the cluster:

   `security key-manager external enable -vserver admin_SVM -key-servers host_name|IP_address:port,... -client-cert client_certificate -server-ca-cert server_CA_certificates`

   > - The `security key-manager external enable` command replaces the `security key-manager setup` command. You can run the `security key-manager external modify` command to change the external key management configuration. Learn more about `security key-manager external enable` in the ONTAP command reference.
   > - In a MetroCluster environment, if you are configuring external key management for the admin SVM, you must repeat the `security key-manager external enable` command on the partner cluster.

   The following command enables external key management for `cluster1` with three external key servers. The first key server is specified using its hostname and port, the second is specified using an IP address and the default port, and the third is specified using an IPv6 address and port:

   ```
   clusterl::> security key-manager external enable -key-servers
   ks1.local:15696,10.0.0.10,[fd20:8b1e:b255:814e:32bd:f35c:832c:5a09]:1234
   -client-cert AdminVserverClientCert -server-ca-certs
   AdminVserverServerCaCert
   ```

2. Verify that all configured KMIP servers are connected:

   `security key-manager external show-status -node node_name -vserver SVM -key -server host_name|IP_address:port -key-server-status available|not-responding|unknown`

   > The `security key-manager external show-status` command replaces the `security key-manager show -status` command.
   > Learn more about `security key-manager external show-status` in the ONTAP command reference.

```
cluster1::> security key-manager external show-status

Node  Vserver  Key Server                                     Status
----  -------  ---------------------------------------
-------------
node1
      cluster1
               10.0.0.10:5696                                 available
               fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234   available
               ks1.local:15696                                available
node2
      cluster1
               10.0.0.10:5696                                 available
               fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234   available
               ks1.local:15696                                available

Related information

- security key-manager setup
- security key-manager external

Enable external key management for hardware-based encryption in ONTAP 9.5 and earlier

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

About this task

ONTAP configures KMIP server connectivity for all nodes in the cluster.

Before you begin

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.
- In a MetroCluster environment, you must install the same KMIP SSL certificate on both clusters.

Steps

1. Configure key manager connectivity for cluster nodes:

   ```
   security key-manager setup
   ```

   The key manager setup starts.

In a MetroCluster environment, you must run this command on both clusters. Learn more about `security key-manager setup` in the ONTAP command reference.

2. Enter the appropriate response at each prompt.
3. Add a KMIP server:

   `security key-manager add -address key_management_server_ipaddress`

```
clusterl::> security key-manager add -address 20.1.1.1
```

   In a MetroCluster environment, you must run this command on both clusters.

4. Add an additional KMIP server for redundancy:

   `security key-manager add -address key_management_server_ipaddress`

```
clusterl::> security key-manager add -address 20.1.1.2
```

   In a MetroCluster environment, you must run this command on both clusters.

5. Verify that all configured KMIP servers are connected:

   `security key-manager show -status`

   Learn more about the commands described in this procedure in the ONTAP command reference.

```
cluster1::> security key-manager show -status

Node              Port      Registered Key Manager  Status
--------------    ----      ----------------------  ---------------
cluster1-01       5696      20.1.1.1                available
cluster1-01       5696      20.1.1.2                available
cluster1-02       5696      20.1.1.1                available
cluster1-02       5696      20.1.1.2                available
```

6. Optionally, convert plain text volumes to encrypted volumes.

   `volume encryption conversion start`

   An external key manager must be fully configured before you convert the volumes. In a MetroCluster environment, an external key manager must be configured on both sites.

Configure clustered external key servers in ONTAP

Beginning with ONTAP 9.11.1, you can configure connectivity to clustered external key management servers on an SVM. With clustered key servers, you can designate primary and secondary key servers on a SVM. When registering keys, ONTAP will first attempt to access a primary key server before sequentially attempting to access secondary servers until the operation completes successfully, preventing duplication of keys.

External key servers can be used for NSE, NVE, NAE, and SED keys. An SVM can support up to four primary external KMIP servers. Each primary server can support up to three secondary key servers.

Before you begin

- KMIP key management must be enabled for the SVM.
- This process only supports key servers that use KMIP. For a list of supported key servers, check the NetApp Interoperability Matrix Tool.
- All nodes in the cluster must be running ONTAP 9.11.1 or later.
- The order of servers list arguments in the `-secondary-key-servers` parameter reflects the access order of the external key management (KMIP) servers.
- Learn more about the commands described in this procedure in the ONTAP command reference.

Create a clustered key server

The configuration procedure depends on whether or not you have configured a primary key server.

Add primary and secondary key servers to an SVM

1. Confirm that no key management has been enabled for the cluster:
   `security key-manager external show -vserver` *`svm_name`*
   If the SVM already has the maximum of four primary key servers enabled, you must remove one of the existing primary key servers before adding a new one.
2. Enable the primary key manager:
   `security key-manager external enable -vserver` *`svm_name`* `-key-servers` *`server_ip`* `-client-cert` *`client_cert_name`* `-server-ca-certs` *`server_ca_cert_names`*
3. Modify the primary key server to add secondary key servers. The `-secondary-key-servers` parameter accepts a comma-separated list of up to three key servers.
   `security key-manager external modify-server -vserver` *`svm_name`* `-key-servers` *`primary_key_server`* `-secondary-key-servers` *`list_of_key_servers`*

Add secondary key servers to an existing primary key server

1. Modify the primary key server to add secondary key servers. The `-secondary-key-servers` parameter accepts a comma-separated list of up to three key servers.
   `security key-manager external modify-server -vserver` *`svm_name`* `-key-servers` *`primary_key_server`* `-secondary-key-servers` *`list_of_key_servers`*
   For more information about secondary key servers, see Modify secondary key servers.

Modify clustered key servers

You can modify external key servers clusters by changing the status (primary or secondary) of particular key servers, add and removing secondary key servers, or by changing the access order of secondary key servers.

Convert primary and secondary key servers

To convert a primary key server into a secondary key server, you must first remove it from the SVM with the `security key-manager external remove-servers` command.

To convert a secondary key server into a primary key server, you must first remove the secondary key server from its existing primary key server. See Modify secondary key servers. If you convert a secondary key server to a primary server while removing an existing key, attempting to add a new server before completing the removal and conversion can result in the the duplication of keys.

Modify secondary key servers

Secondary key servers are managed with the `-secondary-key-servers` parameter of the `security key-manager external modify-server` command. The `-secondary-key-servers` parameter accepts a comma-separated list. The specified order of the secondary key servers in the list determines the access sequence for the secondary key servers. The access order can be modified by running the command `security key-manager external modify-server` with the secondary key servers entered in a different sequence.

To remove a secondary key server, the `-secondary-key-servers` arguments should include the key servers you want to keep while omitting the one to be removed. To remove all secondary key servers, use the argument `-`, signifying none.

* security key-manager external

Create authentication keys in ONTAP 9.6 and later

You can use the `security key-manager key create` command to create the authentication keys for a node and store them on the configured KMIP servers.

About this task

If your security setup requires you to use different keys for data authentication and FIPS 140-2 authentication, you should create a separate key for each. If that’s not the case, you can use the same authentication key for FIPS compliance that you use for data access.

ONTAP creates authentication keys for all nodes in the cluster.

* This command is not supported when Onboard Key Manager is enabled. However, two authentication keys are created automatically when Onboard Key Manager is enabled. The keys can be viewed with the following command:

```
security key-manager key query -key-type NSE-AK
```

* You receive a warning if the configured key management servers are already storing more than 128 authentication keys.
* You can use the `security key-manager key delete` command to delete any unused keys. The `security key-manager key delete` command fails if the given key is currently in use by ONTAP. (You must have privileges greater than `admin` to use this command.)

In a MetroCluster environment, before you delete a key, you must make sure that the key is not in use on the partner cluster. You can use the following commands on the partner cluster to check that the key is not in use:

- `storage encryption disk show -data-key-id <key-id>`
- `storage encryption disk show -fips-key-id <key-id>`

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Create the authentication keys for cluster nodes:

```
security key-manager key create -key-tag <passphrase_label> -prompt-for
-key true|false
```

> Setting `prompt-for-key=true` causes the system to prompt the cluster administrator for the passphrase to use when authenticating encrypted drives. Otherwise, the system automatically generates a 32-byte passphrase. The `security key-manager key create` command replaces the `security key-manager create-key` command. Learn more about `security key-manager key create` in the [ONTAP command reference](#).

The following example creates the authentication keys for `cluster1`, automatically generating a 32-byte passphrase:

```
cluster1::> security key-manager key create
Key ID: <id_value>
```

2. Verify that the authentication keys have been created:

```
security key-manager key query -node node
```

> The `security key-manager key query` command replaces the `security key-manager query key` command.
>
> The key ID displayed in the output is an identifier used to refer to the authentication key. It is not the actual authentication key or the data encryption key.

The following example verifies that authentication keys have been created for `cluster1`:

```
cluster1::> security key-manager key query
       Vserver: cluster1
   Key Manager: external
          Node: node1

Key Tag                               Key Type  Restored
------------------------------------  --------  --------
node1                                 NSE-AK    yes
    Key ID: <id_value>
node1                                 NSE-AK    yes
    Key ID: <id_value>

       Vserver: cluster1
   Key Manager: external
          Node: node2

Key Tag                               Key Type  Restored
------------------------------------  --------  --------
node2                                 NSE-AK    yes
    Key ID: <id_value>
node2                                 NSE-AK    yes
    Key ID: <id_value>
```

Learn more about `security key-manager key query` in the ONTAP command reference.

Create authentication keys in ONTAP 9.5 and earlier

You can use the `security key-manager create-key` command to create the authentication keys for a node and store them on the configured KMIP servers.

About this task

If your security setup requires you to use different keys for data authentication and FIPS 140-2 authentication, you should create a separate key for each. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

ONTAP creates authentication keys for all nodes in the cluster.

- This command is not supported when onboard key management is enabled.
- You receive a warning if the configured key management servers are already storing more than 128 authentication keys.

  You can use the key management server software to delete any unused keys, then run the command again.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Create the authentication keys for cluster nodes:

   `security key-manager create-key`

   Learn more about `security key-manager create-key` in the ONTAP command reference.

   > The key ID displayed in the output is an identifier used to refer to the authentication key. It is not the actual authentication key or the data encryption key.

   The following example creates the authentication keys for `cluster1`:

```
cluster1::> security key-manager create-key
   (security key-manager create-key)
Verifying requirements...

Node: cluster1-01
Creating authentication key...
Authentication key creation successful.
Key ID: <id_value>

Node: cluster1-01
Key manager restore operation initialized.
Successfully restored key information.

Node: cluster1-02
Key manager restore operation initialized.
Successfully restored key information.
```

2. Verify that the authentication keys have been created:

   `security key-manager query`

   Learn more about `security key-manager query` in the ONTAP command reference.

   The following example verifies that authentication keys have been created for `cluster1`:

```
cluster1::> security key-manager query

  (security key-manager query)

          Node: cluster1-01
   Key Manager: 20.1.1.1
 Server Status: available

Key Tag        Key Type  Restored
-------------  --------  --------
cluster1-01    NSE-AK    yes
       Key ID: <id_value>

          Node: cluster1-02
   Key Manager: 20.1.1.1
 Server Status: available

Key Tag        Key Type  Restored
-------------  --------  --------
cluster1-02    NSE-AK    yes
       Key ID: <id_value>
```

Assign a data authentication key to a FIPS drive or SED with ONTAP external key management

You can use the `storage encryption disk modify` command to assign a data authentication key to a FIPS drive or SED. Cluster nodes use this key to lock or unlock encrypted data on the drive.

About this task

A self-encrypting drive is protected from unauthorized access only if its authentication key ID is set to a non-default value. The manufacturer secure ID (MSID), which has key ID 0x0, is the standard default value for SAS drives. For NVMe drives, the standard default value is a null key, represented as a blank key ID. When you assign the key ID to a self-encrypting drive, the system changes its authentication key ID to a non-default value.

This procedure is not disruptive.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Assign a data authentication key to a FIPS drive or SED:

   `storage encryption disk modify -disk *disk_ID* -data-key-id *key_ID*`

   Learn more about `storage encryption disk modify` in the ONTAP command reference.

You can use the `security key-manager query -key-type NSE-AK` command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 0.10.* -data-key-id
<id_value>

Info: Starting modify on 14 disks.
      View the status of the operation by using the
      storage encryption disk show-status command.
```

2. Verify that the authentication keys have been assigned:

   `storage encryption disk show`

   Learn more about `storage encryption disk show` in the ONTAP command reference.

```
cluster1::> storage encryption disk show
Disk    Mode Data Key ID
-----   ----
----------------------------------------------------------------
0.0.0   data <id_value>
0.0.1   data <id_value>
[...]
```

Configure onboard key management

Enable onboard key management in ONTAP 9.6 and later

You can use the Onboard Key Manager to authenticate cluster nodes to a FIPS drive or SED. The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data. The Onboard Key Manager is FIPS-140-2 level 1 compliant.

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

About this task

You must run the `security key-manager onboard enable` command each time you add a node to the cluster. In MetroCluster configurations, you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.

Learn more about `security key-manager onboard enable` and `security key-manager onboard sync` in the ONTAP command reference.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Except in MetroCluster, you can use the `cc-mode-enabled=yes` option to require that users enter the passphrase after a reboot.

> When the Onboard Key Manager is enabled in Common Criteria mode (`cc-mode-enabled=yes`), system behavior is changed in the following ways:
>
> - The system monitors for consecutive failed cluster passphrase attempts when operating in Common Criteria mode.
>
>   If NetApp Storage Encryption (NSE) is enabled and you fail to enter the correct cluster passphrase at boot, the system cannot authenticate to its drives and automatically reboots. To correct this, you must enter the correct cluster passphrase at the boot prompt. Once booted, the system allows up to 5 consecutive attempts to correctly enter the cluster passphrase in a 24-hour period for any command that requires the cluster passphrase as a parameter. If the limit is reached (for example, you have failed to correctly enter the cluster passphrase 5 times in a row) then you must either wait for the 24-hour timeout period to elapse, or you must reboot the node, in order to reset the limit.
>
> - System image updates use the NetApp RSA-3072 code signing certificate together with SHA-384 code signed digests to check the image integrity instead of the usual NetApp RSA-2048 code signing certificate and SHA-256 code signed digests.
>
>   The upgrade command verifies that the image contents have not been altered or corrupted by checking various digital signatures. The image update process proceeds to the next step if validation succeeds; otherwise, the image update fails. Learn more about `cluster image` in the ONTAP command reference.

> The Onboard Key Manager stores keys in volatile memory. Volatile memory contents are cleared when the system is rebooted or halted. Under normal operating conditions, volatile memory contents will be cleared within 30s when a system is halted.

Before you begin

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

  Transitioning to onboard key management from external key management

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before the Onboard Key Manager is configured.

Steps

1. Start the key manager setup command:

   ```
   security key-manager onboard enable -cc-mode-enabled yes|no
   ```

   > Set `cc-mode-enabled=yes` to require that users enter the key manager passphrase after a reboot. The `- cc-mode-enabled` option is not supported in MetroCluster configurations. The `security key-manager onboard enable` command replaces the `security key-manager setup` command.

The following example starts the key manager setup command on cluster1 without requiring that the passphrase be entered after every reboot:

```
cluster1::> security key-manager onboard enable

Enter the cluster-wide passphrase for onboard key management in Vserver
"cluster1"::    <32..256 ASCII characters long text>
Reenter the cluster-wide passphrase:    <32..256 ASCII characters long
text>
```

2. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

   If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

3. At the passphrase confirmation prompt, reenter the passphrase.
4. Verify that the authentication keys have been created:

   `security key-manager key query -node node`

   The `security key-manager key query` command replaces the `security key-manager query key` command.

   The following example verifies that authentication keys have been created for `cluster1`:

```
cluster1::> security key-manager key query
       Vserver: cluster1
   Key Manager: onboard
          Node: node1

Key Tag                               Key Type  Restored
------------------------------------  --------  --------
node1                                 NSE-AK    yes
    Key ID: <id_value>
node1                                 NSE-AK    yes
    Key ID: <id_value>

       Vserver: cluster1
   Key Manager: onboard
          Node: node2

Key Tag                               Key Type  Restored
------------------------------------  --------  --------
node1                                 NSE-AK    yes
    Key ID: <id_value>
node2                                 NSE-AK    yes
    Key ID: <id_value>
```

Learn more about `security key-manager key query` in the ONTAP command reference.

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up the information manually for use in case of a disaster.

Related information

- security key-manager setup

Enable onboard key management in ONTAP 9.5 and earlier

You can use the Onboard Key Manager to authenticate cluster nodes to a FIPS drive or SED. The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data. The Onboard Key Manager is FIPS-140-2 level 1 compliant.

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

About this task

You must run the `security key-manager setup` command each time you add a node to the cluster.

If you have a MetroCluster configuration, review these guidelines:

- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

> After a failed passphrase attempt, you must reboot the node again.

Before you begin

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

  Transitioning to onboard key management from external key management

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before the Onboard Key Manager is configured.

Steps

1. Start the key manager setup:

   ```
   security key-manager setup -enable-cc-mode yes|no
   ```

   > Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the key manager passphrase after a reboot. For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted.

   The following example starts setting up the key manager on cluster1 without requiring that the passphrase be entered after every reboot:

```
cluster1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.

...

Would you like to use onboard key-management? {yes, no} [yes]:
Enter the cluster-wide passphrase:    <32..256 ASCII characters long
text>
Reenter the cluster-wide passphrase:    <32..256 ASCII characters long
text>
```

2. Enter `yes` at the prompt to configure onboard key management.
3. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

   > If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

4. At the passphrase confirmation prompt, reenter the passphrase.
5. Verify that keys are configured for all nodes:

   `security key-manager key show`

   Learn more about `security key-manager key show` in the ONTAP command reference.

```
cluster1::> security key-manager key show

Node: node1
Key Store: onboard
Key ID                                                                  Used By
----------------------------------------------------------------
--------
<id_value> NSE-AK
<id_value> NSE-AK

Node: node2
Key Store: onboard
Key ID                                                                  Used By
----------------------------------------------------------------
--------
<id_value> NSE-AK
<id_value> NSE-AK
```

After you finish

All key management information is automatically backed up to the replicated database (RDB) for the cluster.

Whenever you configure the Onboard Key Manager passphrase, you should also back up the information manually to a secure location outside the storage system for use in case of a disaster. See Back up onboard key management information manually.

- security key-manager setup

Assign a data authentication key to a FIPS drive or SED with ONTAP onboard key management

You can use the `storage encryption disk modify` command to assign a data authentication key to a FIPS drive or SED. Cluster nodes use this key to access data on the drive.

About this task

A self-encrypting drive is protected from unauthorized access only if its authentication key ID is set to a non-default value. The manufacturer secure ID (MSID), which has key ID 0x0, is the standard default value for SAS drives. For NVMe drives, the standard default value is a null key, represented as a blank key ID. When you assign the key ID to a self-encrypting drive, the system changes its authentication key ID to a non-default value.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Assign a data authentication key to a FIPS drive or SED:

   `storage encryption disk modify -disk` *`disk_ID`* `-data-key-id` *`key_ID`*

   Learn more about `storage encryption disk modify` in the ONTAP command reference.

   > You can use the `security key-manager key query -key-type NSE-AK` command to view key IDs.

   ```
   cluster1::> storage encryption disk modify -disk 0.10.* -data-key-id
   <id_value>

   Info: Starting modify on 14 disks.
         View the status of the operation by using the
         storage encryption disk show-status command.
   ```

   Learn more about `security key-manager key query` in the ONTAP command reference.

2. Verify that the authentication keys have been assigned:

   `storage encryption disk show`

Learn more about `storage encryption disk show` in the ONTAP command reference.

```
cluster1::> storage encryption disk show
Disk    Mode Data Key ID
-----   ----
----------------------------------------------------------------
0.0.0   data <id_value>
0.0.1   data <id_value>
[...]
```

Assign a FIPS 140-2 authentication key to an ONTAP FIPS drive

You can use the `storage encryption disk modify` command with the `-fips-key-id` option to assign a FIPS 140-2 authentication key to a FIPS drive. Cluster nodes use this key for drive operations other than data access, such as preventing denial-of-service attacks on the drive.

About this task

Your security setup may require you to use different keys for data authentication and FIPS 140-2 authentication. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

This procedure is not disruptive.

Before you begin

The drive firmware must support FIPS 140-2 compliance. The NetApp Interoperability Matrix Tool contains information about supported drive firmware versions.

Steps

1. You must first ensure you have assigned a data authentication key. This can be done with using an external key manager or an onboard key manager. Verify the key is assigned with the command `storage encryption disk show`.
2. Assign a FIPS 140-2 authentication key to SEDs:

   `storage encryption disk modify -disk` *`disk_id`* `-fips-key-id` *`fips_authentication_key_id`*

   You can use the `security key-manager query` command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 2.10.* -fips-key-id
<id_value>

Info: Starting modify on 14 disks.
      View the status of the operation by using the
      storage encryption disk show-status command.
```

3. Verify that the authentication key has been assigned:

   `storage encryption disk show -fips`

   Learn more about `storage encryption disk show` in the ONTAP command reference.

```
cluster1::> storage encryption disk show -fips
Disk     Mode FIPS-Compliance Key ID
------  ----
----------------------------------------------------------------
2.10.0   full <id_value>
2.10.1   full <id_value>
[...]
```

Enable cluster-wide FIPS-compliant mode for KMIP server connections in ONTAP

You can use the `security config modify` command with the `-is-fips-enabled` option to enable cluster-wide FIPS-compliant mode for data in flight. Doing so forces the cluster to use OpenSSL in FIPS mode when connecting to KMIP servers.

About this task

When you enable cluster-wide FIPS-compliant mode, the cluster will automatically use only TLS1.2 and FIPS-validated cipher suites. Cluster-wide FIPS-compliant mode is disabled by default.

You must reboot cluster nodes manually after modifying the cluster-wide security configuration.

Before you begin

- The storage controller must be configured in FIPS-compliant mode.
- All KMIP servers must support TLSv1.2. The system requires TLSv1.2 to complete the connection to the KMIP server when cluster-wide FIPS-compliant mode is enabled.

Steps

1. Set the privilege level to advanced:

   `set -privilege advanced`

2. Verify that TLSv1.2 is supported:

   `security config show -supported-protocols`

   Learn more about `security config show` in the ONTAP command reference.

```
cluster1::> security config show
          Cluster                                              Cluster
Security
Interface FIPS Mode  Supported Protocols     Supported Ciphers Config
Ready
--------- ---------- ----------------------- -----------------
----------------
SSL       false      TLSv1.2, TLSv1.1, TLSv1 ALL:!LOW:         yes
                                             !aNULL:!EXP:
                                             !eNULL
```

3. Enable cluster-wide FIPS-compliant mode:

   `security config modify -is-fips-enabled true -interface SSL`

   Learn more about `security config modify` in the ONTAP command reference.

4. Reboot cluster nodes manually.
5. Verify that cluster-wide FIPS-compliant mode is enabled:

   `security config show`

```
cluster1::> security config show
          Cluster                                              Cluster
Security
Interface FIPS Mode  Supported Protocols     Supported Ciphers Config
Ready
--------- ---------- ----------------------- -----------------
----------------
SSL       true       TLSv1.2, TLSv1.1        ALL:!LOW:         yes
                                             !aNULL:!EXP:
                                             !eNULL:!RC4
```

Manage NetApp encryption

Unencrypt volume data in ONTAP

You can use the `volume move start` command to move and unencrypt volume data.

Before you begin

You must be a cluster administrator to perform this task. Alternately, you can be an SVM administrator to whom the cluster administrator has delegated authority. For more information, see Delegate authority to run the volume move command.

Steps

1. Move an existing encrypted volume and unencrypt the data on the volume:

   `volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-destination false`

   Learn more about `volume move start` in the ONTAP command reference.

   The following command moves an existing volume named `vol1` to the destination aggregate `aggr3` and unencrypts the data on the volume:

   ```
   cluster1::> volume move start -vserver vs1 -volume vol1 -destination
   -aggregate aggr3 -encrypt-destination false
   ```

   The system deletes the encryption key for the volume. The data on the volume is unencrypted.

2. Verify that the volume is disabled for encryption:

   `volume show -encryption`

   Learn more about `volume show` in the ONTAP command reference.

   The following command displays whether volumes on `cluster1` are encrypted:

   ```
   cluster1::> volume show -encryption

   Vserver  Volume  Aggregate  State   Encryption State
   -------- ------  ---------  -----   ----------------
   vs1      vol1    aggr1      online  none
   ```

Move an encrypted volume in ONTAP

You can use the `volume move start` command to move an encrypted volume. The moved volume can reside on the same aggregate or a different aggregate.

About this task

The move will fail if the destination node or destination volume does not support volume encryption.

The `-encrypt-destination` option for `volume move start` defaults to true for encrypted volumes. The requirement to specify you do not want the destination volume encrypted ensures that you do not inadvertently unencrypt the data on the volume.

Before you begin

You must be a cluster administrator to perform this task. Alternately, you can be an SVM administrator to whom the cluster administrator has delegated authority. For more information, see delegate authority to run the volume move command.

Steps

1. Move an existing encrypted volume and leave the data on the volume encrypted:

`volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name`

Learn more about `volume move start` in the ONTAP command reference.

The following command moves an existing volume named `vol1` to the destination aggregate `aggr3` and leaves the data on the volume encrypted:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination
-aggregate aggr3
```

2. Verify that the volume is enabled for encryption:

   `volume show -is-encrypted true`

   Learn more about `volume show` in the ONTAP command reference.

   The following command displays the encrypted volumes on `cluster1`:

```
cluster1::> volume show -is-encrypted true

Vserver  Volume  Aggregate  State  Type  Size  Available  Used
-------  ------  ---------  -----  ----  -----  ---------  ----
vs1      vol1    aggr3     online    RW  200GB    160.0GB  20%
```

Delegate authority to run the volume move command in ONTAP

You can use the `volume move` command to encrypt an existing volume, move an encrypted volume, or unencrypt a volume. Cluster administrators can run `volume move` command themselves, or they can delegate the authority to run the command to SVM administrators.

About this task

By default, SVM administrators are assigned the `vsadmin` role, which does not include the authority to move volumes. You must assign the `vsadmin-volume` role to SVM administrators to enable them to run the `volume move` command.

Step

1. Delegate authority to run the `volume move` command:

   `security login modify -vserver SVM_name -user-or-group-name user_or_group_name -application application -authmethod authentication_method -role vsadmin-volume`

   The following command grants the SVM administrator authority to run the `volume move` command.

```
cluster1::>security login modify -vserver engData -user-or-group-name
SVM-admin -application ssh -authmethod domain -role vsadmin-volume
```

Learn more about `security login modify` in the ONTAP command reference.

Change the encryption key for a volume with the volume encryption rekey start command in ONTAP

It is a security best practice to change the encryption key for a volume periodically. Beginning with ONTAP 9.3, you can use the `volume encryption rekey start` command to change the encryption key.

About this task

Once you start a rekey operation, it must complete. There is no returning to the old key. If you encounter a performance issue during the operation, you can run the `volume encryption rekey pause` command to pause the operation, and the `volume encryption rekey resume` command to resume the operation.

Until the rekey operation finishes, the volume will have two keys. New writes and their corresponding reads will use the new key. Otherwise, reads will use the old key.

> You cannot use `volume encryption rekey start` to rekey a SnapLock volume.

Steps

1. Change an encryption key:

   `volume encryption rekey start -vserver SVM_name -volume volume_name`

   The following command changes the encryption key for `vol1` on SVM`vs1`:

   ```
   cluster1::> volume encryption rekey start -vserver vs1 -volume vol1
   ```

2. Verify the status of the rekey operation:

   `volume encryption rekey show`

   Learn more about `volume encryption rekey show` in the ONTAP command reference.

   The following command displays the status of the rekey operation:

   ```
   cluster1::> volume encryption rekey show

   Vserver   Volume   Start Time           Status
   -------   ------   ------------------   ---------------------------
   vs1       vol1     9/18/2017 17:51:41   Phase 2 of 2 is in progress.
   ```

3. When the rekey operation is complete, verify that the volume is enabled for encryption:

`volume show -is-encrypted true`

Learn more about `volume show` in the ONTAP command reference.

The following command displays the encrypted volumes on `cluster1`:

```
cluster1::> volume show -is-encrypted true

Vserver  Volume  Aggregate  State  Type  Size  Available  Used
-------  ------  ---------  -----  ----  -----  --------- ----
vs1      vol1    aggr2     online    RW  200GB    160.0GB  20%
```

Change the encryption key for a volume with the ONTAP volume move start command

It is a security best practice to change the encryption key for a volume periodically. You can use the `volume move start` command to change the encryption key. The moved volume can reside on the same aggregate or a different aggregate.

About this task

You cannot use `volume move start` to rekey a SnapLock or FlexGroup volume.

Before you begin

You must be a cluster administrator to perform this task. Alternately, you can be an SVM administrator to whom the cluster administrator has delegated authority. For more information, see delegate authority to run the volume move command.

Steps

1. Move an existing volume and change the encryption key:

   `volume move start -vserver` *`SVM_name`* `-volume` *`volume_name`* `-destination-aggregate` *`aggregate_name`* `-generate-destination-key true`

   Learn more about `volume move start` in the ONTAP command reference.

   The following command moves an existing volume named **`vol1`** to the destination aggregate **`aggr2`** and changes the encryption key:

   ```
   cluster1::> volume move start -vserver vs1 -volume vol1 -destination
   -aggregate aggr2 -generate-destination-key true
   ```

   A new encryption key is created for the volume. The data on the volume remains encrypted.

2. Verify that the volume is enabled for encryption:

   `volume show -is-encrypted true`

   Learn more about `volume show` in the ONTAP command reference.

The following command displays the encrypted volumes on `cluster1`:

```
cluster1::> volume show -is-encrypted true

Vserver  Volume  Aggregate  State  Type  Size  Available  Used
-------- ------  ---------  -----  ----  -----  ---------- ----
vs1      vol1    aggr2     online    RW  200GB    160.0GB  20%
```

Rotate authentication keys for ONTAP NetApp Storage Encryption

You can rotate authentication keys when using NetApp Storage Encryption (NSE).

About this task

Rotating authentication keys in an NSE environment is supported if you are using External Key Manager (KMIP).

> Rotating authentication keys in an NSE environment is not supported for Onboard Key Manager (OKM).

Steps

1. Use the `security key-manager create-key` command to generate new authentication keys.

   You need to generate new authentication keys before you can change the authentication keys.

2. Use the `storage encryption disk modify -disk * -data-key-id` command to change the authentication keys.

Delete an encrypted volume in ONTAP

You can use the `volume delete` command to delete an encrypted volume.

Before you begin

- You must be a cluster administrator to perform this task. Alternately, you can be an SVM administrator to whom the cluster administrator has delegated authority. For more information, see delegate authority to run the volume move command.
- The volume must be offline.

Step

1. Delete an encrypted volume:

   `volume delete -vserver SVM_name -volume volume_name`

   Learn more about `volume delete` in the ONTAP command reference.

   The following command deletes an encrypted volume named `vol1`:

```
cluster1::> volume delete -vserver vs1 -volume vol1
```

Enter `yes` when you are prompted to confirm deletion.

The system deletes the encryption key for the volume after 24 hours.

Use `volume delete` with the `-force true` option to delete a volume and destroy the corresponding encryption key immediately. This command requires advanced privileges.
Learn more about `volume delete` in the ONTAP command reference.

After you finish

You can use the `volume recovery-queue` command to recover a deleted volume during the retention period after issuing the `volume delete` command:

```
volume recovery-queue SVM_name -volume volume_name
```

How to use the Volume Recovery feature

Securely purge data on an encrypted volume

Learn about securely purging data from an encrypted ONTAP volume

Beginning with ONTAP 9.4, you can use secure purge to non-disruptively scrub data on NVE-enabled volumes. Scrubbing data on an encrypted volume ensures that it cannot be recovered from the physical media, for example, in cases of “spillage,” where data traces may have been left behind when blocks were overwritten, or for securely deleting a vacating tenant’s data.

Secure purge works only for previously deleted files on NVE-enabled volumes. You cannot scrub an unencrypted volume. You must use KMIP servers to serve keys, not the onboard key manager.

Considerations for using secure purge

- Volumes created in an aggregate enabled for NetApp Aggregate Encryption (NAE) do not support secure purge.
- Secure purge works only for previously deleted files on NVE-enabled volumes.
- You cannot scrub an unencrypted volume.
- You must use KMIP servers to serve keys, not the onboard key manager.

Secure purge functions differently depending upon your version of ONTAP.

ONTAP 9.8 and later

- Secure purge is supported by MetroCluster and FlexGroup.
- If the volume being purged is the source of a SnapMirror relationship, you do not have to break the SnapMirror relationship to perform a secure purge.
- The re-encryption method is different for volumes using SnapMirror data protection versus volumes not using SnapMirror data protection (DP) or those using SnapMirror extended data protection..
    - By default, volumes using SnapMirror data protection (DP) mode re-encrypt data using the volume move re-encryption method.
    - By default, volumes not using SnapMirror data protection or volumes using SnapMirror extended data protection (XDP) mode use the in-place re-encryption method.
    - These defaults can be changed using the `secure purge re-encryption-method [volume-move|in-place-rekey]` command.
- By default, all snapshots in FlexVol volumes are automatically deleted during the secure purge operation. By default, Snapshots in FlexGroup volumes and volumes using SnapMirror data protection are not automatically deleted during the secure purge operation. These defaults can be changed using the `secure purge delete-all-snapshots [true|false]` command.

ONTAP 9.7 and earlier:

- Secure purge does not support the following:
    - FlexClone
    - SnapVault
    - FabricPool
- If the volume being purged is the source of a SnapMirror relationship, you must break the SnapMirror relationship before you can purge the volume.

  If there are busy snapshots in the volume, you must release the snapshots before you can purge the volume. For example, you may need to split a FlexClone volume from its parent.
- Successfully invoking the secure-purge feature triggers a volume move that re-encrypts the remaining, unpurged data with a new key.

  The moved volume remains on the current aggregate. The old key is automatically destroyed, ensuring that purged data cannot be recovered from the storage media.

Scrub data from an encrypted ONTAP volume without a SnapMirror relationship

Beginning with ONTAP 9.4, you can use secure-purge to non-disruptively “scrub” data on NVE-enabled volumes.

About this task

Secure-purge may take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

> In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Before you begin

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

Steps

1. Delete the files or the LUN you want to securely purge.
   - On a NAS client, delete the files you want to securely purge.
   - On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.
2. On the storage system, change to advanced privilege level:

   `set -privilege advanced`

3. If the files you want to securely purge are in snapshots, delete the snapshots:

   `snapshot delete -vserver *SVM_name* -volume *volume_name* -snapshot`

4. Securely purge the deleted files:

   `volume encryption secure-purge start -vserver *SVM_name* -volume *volume_name*`

   The following command securely purges the deleted files on `vol1` on SVM`vs1`:

   ```
   cluster1::> volume encryption secure-purge start -vserver vs1 -volume
   vol1
   ```

5. Verify the status of the secure-purge operation:

   `volume encryption secure-purge show`

Scrub data from an encrypted ONTAP volume with an SnapMirror asynchronous relationship

Beginning with ONTAP 9.8, you can use a secure purge to non-disruptively “scrub” data on NVE-enabled volumes with an SnapMirror asynchronous relationship.

Before you begin

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

Secure-purge may take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

> In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Steps

1. On the storage system, switch to the advanced privilege level:

   `set -privilege advanced`

2. Delete the files or the LUN you want to securely purge.
   - On a NAS client, delete the files you want to securely purge.
   - On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.
3. Prepare the destination volume in the Asynchronous relationship to be securely purged:

   `volume encryption secure-purge start -vserver SVM_name -volume volume_name -prepare true`

   Repeat this step on each volume in your SnapMirror asynchronous relationship.

4. If the files you want to securely purge are in snapshots, delete the snapshots:

   `snapshot delete -vserver SVM_name -volume volume_name -snapshot`

5. If the files you want to securely purge are in the base snapshots, do the following:
   a. Create a snapshot on the destination volume in the SnapMirror asynchronous relationship:

      `volume snapshot create -snapshot snapshot_name -vserver SVM_name -volume volume_name`

   b. Update SnapMirror to move the base snapshot forward:

      `snapmirror update -source-snapshot snapshot_name -destination-path destination_path`

      Repeat this step for each volume in the SnapMirror asynchronous relationship.

   c. Repeat steps (a) and (b) equal to the number of base snapshots plus one.

      For example, if you have two base snapshots, you should repeat steps (a) and (b) three times.

   d. Verify that the base snapshot is present:

      `snapshot show -vserver SVM_name -volume volume_name`

   e. Delete the base snapshot:

      `snapshot delete -vserver svm_name -volume volume_name -snapshot snapshot`

6. Securely purge the deleted files:

   `volume encryption secure-purge start -vserver svm_name -volume volume_name`

   Repeat this step on each volume in the SnapMirror asynchronous relationship.

   The following command securely purges the deleted files on "vol1" on SVM "vs1":

   ```
   cluster1::> volume encryption secure-purge start -vserver vs1 -volume
   vol1
   ```

7. Verify the status of the secure purge operation:

   `volume encryption secure-purge show`

* snapmirror update

Scrub data from an encrypted ONTAP volume with a SnapMirror synchronous relationship

Beginning with ONTAP 9.8, you can use a secure purge to non-disruptively "scrub" data on NVE-enabled volumes with a SnapMirror synchronous relationship.

About this task

A secure purge might take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

> In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Before you begin

* You must be a cluster administrator to perform this task.
* Advanced privileges are required for this task.

Steps

1. On the storage system, change to advanced privilege level:

   `set -privilege advanced`

2. Delete the files or the LUN you want to securely purge.
   * On a NAS client, delete the files you want to securely purge.
   * On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.
3. Prepare the destination volume in the Asynchronous relationship to be securely purged:

```
volume encryption secure-purge start -vserver <SVM_name> -volume <volume_name>
-prepare true
```

Repeat this step for the other volume in your SnapMirror synchronous relationship.

4. If the files you want to securely purge are in snapshots, delete the snapshots:

```
snapshot delete -vserver <SVM_name> -volume <volume_name> -snapshot <snapshot>
```

5. If the secure purge file is in the base or common snapshots, update the SnapMirror to move the common snapshot forward:

```
snapmirror update -source-snapshot <snapshot_name> -destination-path
<destination_path>
```

There are two common snapshots, so this command must be issued twice.

6. If the secure purge file is in the application-consistent snapshot, delete the snapshot on both volumes in the SnapMirror synchronous relationship:

```
snapshot delete -vserver <SVM_name> -volume <volume_name> -snapshot <snapshot>
```

Perform this step on both volumes.

7. Securely purge the deleted files:

```
volume encryption secure-purge start -vserver <SVM_name> -volume <volume_name>
```

Repeat this step on each volume in the SnapMirror synchronous relationship.

The following command securely purges the deleted files on “vol1” on SVM “vs1”.

```
cluster1::> volume encryption secure-purge start -vserver vs1 -volume
vol1
```

8. Verify the status of the secure purge operation:

```
volume encryption secure-purge show
```

- snapmirror update

Change the ONTAP onboard key management passphrase

It is a security best practice to change the onboard key management passphrase periodically. You should copy the new onboard key management passphrase to a secure location outside the storage system for future use.

Before you begin

- You must be a cluster or SVM administrator to perform this task.

* Advanced privileges are required for this task.

Steps

1. Change to advanced privilege level:

   `set -privilege advanced`

2. Change the onboard key management passphrase:

For this ONTAP version…	Use this command…
ONTAP 9.6 and later	`security key-manager onboard update-passphrase`
ONTAP 9.5 and earlier	`security key-manager update-passphrase`

   The following ONTAP 9.6 command lets you change the onboard key management passphrase for `cluster1`:

   ```
   cluster1::> security key-manager onboard update-passphrase
   Warning: This command will reconfigure the cluster passphrase for
   onboard key management for Vserver "cluster1".
   Do you want to continue? {y|n}: y
   Enter current passphrase:
   Enter new passphrase:
   ```

3. Enter `y` at the prompt to change the onboard key management passphrase.
4. Enter the current passphrase at the current passphrase prompt.
5. At the new passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

   If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

6. At the passphrase confirmation prompt, reenter the passphrase.

After you finish

In a MetroCluster environment, you must update the passphrase on the partner cluster:

* In ONTAP 9.5 and earlier, you must run `security key-manager update-passphrase` with the same passphrase on the partner cluster.
* In ONTAP 9.6 and later, you are prompted to run `security key-manager onboard sync` with the same passphrase on the partner cluster.

You should copy the onboard key management passphrase to a secure location outside the storage system for future use.

You should back up key management information manually whenever you change the onboard key management passphrase.

Related information

- Backing up onboard key management information manually
- security key-manager onboard update-passphrase
- security key-manager update-passphrase

Back up ONTAP onboard key management information manually

You should copy onboard key management information to a secure location outside the storage system whenever you configure the Onboard Key Manager passphrase.

Before you begin

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up key management information manually for use in case of a disaster.

Steps

1. Change to advanced privilege level:

   ```
   set -privilege advanced
   ```

2. Display the key management backup information for the cluster:

For this ONTAP version…	Use this command…
ONTAP 9.6 and later	`security key-manager onboard show-backup`
ONTAP 9.5 and earlier	`security key-manager backup show`

   The following 9.6 command displays the key management backup information for `cluster1`:

```
cluster1::> security key-manager onboard show-backup

Restore onboard key management encryption keys in ONTAP

The procedure you follow to restore your onboard key management encryption keys varies based on your version of ONTAP.

Before you begin

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database. For more information, see Transition from external key management to ONTAP onboard key management.
- You must be a cluster administrator to perform this task.

> If you are using NSE on a system with a Flash Cache module, you should also enable NVE or NAE. NSE does not encrypt data that resides on the Flash Cache module.

ONTAP 9.6 and later

> If you are running ONTAP 9.8 or later and your root volume is encrypted, follow the procedure for ONTAP 9.8 or later with encrypted root volume.

1. Verify that the key needs to be restored:
   `security key-manager key query -node` *`node`*

   Learn more about `security key-manager key query` in the ONTAP command reference.

2. Restore the key:
   `security key-manager onboard sync`

   The following ONTAP 9.6 command synchronize the keys in the onboard key hierarchy:

   ```
   cluster1::> security key-manager onboard sync

   Enter the cluster-wide passphrase for onboard key management in Vserver
   "cluster1"::    <32..256 ASCII characters long text>
   ```

   Learn more about `security key-manager onboard sync` in the ONTAP command reference.

3. At the passphrase prompt, enter the onboard key management passphrase for the cluster.

ONTAP 9.8 or later with encrypted root volume

If you are running ONTAP 9.8 and later, and your root volume is encrypted, you must set an onboard key management recovery passphrase with the boot menu. This process is also necessary if you do a boot media replacement.

1. Boot the node to the boot menu and select option `(10) Set onboard key management recovery secrets`.
2. Enter `y` to use this option.
3. At the prompt, enter the onboard key management passphrase for the cluster.
4. At the prompt, enter the backup key data.

   The node returns to the boot menu.

5. From the boot menu, select option `(1) Normal Boot`.

ONTAP 9.5 and earlier

1. Verify that the key needs to be restored:
   `security key-manager key show`
2. If you are running ONTAP 9.8 and later, and your root volume is encrypted, complete these steps:

   If you are running ONTAP 9.6 or 9.7, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

3. Restore the key:
   `security key-manager setup -node` *`node`*

   Learn more about `security key-manager setup` in the ONTAP command reference.

4. At the passphrase prompt, enter the onboard key management passphrase for the cluster.

Restore ONTAP external key management encryption keys

You can manually restore external key management encryption keys and push them to a different node. You might want to do this if you are restarting a node that was down temporarily when you created the keys for the cluster.

About this task

In ONTAP 9.6 and later, you can use the `security key-manager key query -node node_name` command to verify if your key needs to be restored.

In ONTAP 9.5 and earlier, you can use the `security key-manager key show` command to verify if your key needs to be restored.

> If you are using NSE on a system with a Flash Cache module, you should also enable NVE or NAE. NSE does not encrypt data that resides on the Flash Cache module.

Learn more about `security key-manager key query` in the ONTAP command reference.

Before you begin

You must be a cluster or SVM administrator to perform this task.

Steps

1. If you are running ONTAP 9.8 or later and your root volume is encrypted, do the following:

   If you are running ONTAP 9.7 or earlier, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

   a. Set the bootargs:

      ```
      setenv kmip.init.ipaddr <ip-address>
      ```

      ```
      setenv kmip.init.netmask <netmask>
      ```

      ```
      setenv kmip.init.gateway <gateway>
      ```

      ```
      setenv kmip.init.interface e0M
      ```

`boot_ontap`

b. Boot the node to the boot menu and select option `(11) Configure node for external key management`.

c. Follow prompts to enter management certificate.

   After all management certificate information is entered, the system returns to the boot menu.

d. From the boot menu, select option `(1) Normal Boot`.

2. Restore the key:

For this ONTAP version…	Use this command…
ONTAP 9.6 and later	`security key-manager external restore -vserver SVM -node node -key-server host_name|IP_address:port -key-id key_id -key-tag key_tag`
ONTAP 9.5 and earlier	`security key-manager restore -node node -address IP_address -key-id key_id -key-tag key_tag`

> `node` defaults to all nodes.
>
> This command is not supported when onboard key management is enabled.

The following ONTAP 9.6 command restores external key management authentication keys to all nodes in `cluster1`:

```
cluster1::> security key-manager external restore
```

Replace KMIP SSL certificates on the ONTAP cluster

All SSL certificates have an expiration date. You must update your certificates before they expire to prevent loss of access to authentication keys.

Before you begin

- You must have obtained the replacement public certificate and private key for the cluster (KMIP client certificate).
- You must have obtained the replacement public certificate for the KMIP server (KMIP server-ca certificate).
- You must be a cluster or SVM administrator to perform this task.
- If you are replacing the KMIP SSL certificates in a MetroCluster environment, you must install the same replacement KMIP SSL certificate on both clusters.

You can install the replacement client and server certificates on the KMIP server before or after installing the certificates on the cluster.

Steps

1. Install the new KMIP server-ca certificate:

   ```
   security certificate install -type server-ca -vserver <>
   ```

2. Install the new KMIP client certificate:

   ```
   security certificate install -type client -vserver <>
   ```

3. Update the key manager configuration to use the newly installed certificates:

   ```
   security key-manager external modify -vserver <> -client-cert <> -server-ca
   -certs <>
   ```

   If you are running ONTAP 9.6 or later in a MetroCluster environment, and you want to modify the key manager configuration on the admin SVM, you must run the command on both clusters in the configuration.

   Updating the key manager configuration to use the newly installed certificates will return an error if the public/private keys of the new client certificate are different from the keys previously installed. See the Knowledge Base article The new client certificate public or private keys are different from the existing client certificate for instructions on how to override this error.

- security certificate install
- security key-manager external modify

Replace a FIPS drive or SED in ONTAP

You can replace a FIPS drive or SED the same way you replace an ordinary disk. Make sure to assign new data authentication keys to the replacement drive. For a FIPS drive, you may also want to assign a new FIPS 140-2 authentication key.

If an HA pair is using encrypting SAS or NVMe drives (SED, NSE, FIPS), you must follow the instructions in the topic Returning a FIPS drive or SED to unprotected mode for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

Before you begin

- You must know the key ID for the authentication key used by the drive.
- You must be a cluster administrator to perform this task.

Steps

1. Ensure that the disk has been marked as failed:

   ```
   storage disk show -broken
   ```

Learn more about `storage disk show` in the ONTAP command reference.

```
cluster1::> storage disk show -broken
Original Owner: cluster1-01
  Checksum Compatibility: block
                                                                    Usable
Physical
    Disk    Outage Reason HA Shelf Bay Chan   Pool  Type    RPM     Size
Size
    ------ ---- ------------ ---- --- ---- ------ -----  -----  -------
-------
    0.0.0  admin  failed  0b    1   0    A  Pool0  FCAL  10000  132.8GB
133.9GB
    0.0.7  admin  removed 0b    2   6    A  Pool1  FCAL  10000  132.8GB
134.2GB
[...]
```

2. Remove the failed disk and replace it with a new FIPS drive or SED, following the instructions in the hardware guide for your disk shelf model.
3. Assign ownership of the newly replaced disk:

   `storage disk assign -disk disk_name -owner node`

   Learn more about `storage disk assign` in the ONTAP command reference.

```
cluster1::> storage disk assign -disk 2.1.1 -owner cluster1-01
```

4. Confirm that the new disk has been assigned:

   `storage encryption disk show`

   Learn more about `storage encryption disk show` in the ONTAP command reference.

```
cluster1::> storage encryption disk show
Disk    Mode Data Key ID
-----   ----
----------------------------------------------------------------
0.0.0   data <id_value>
0.0.1   data <id_value>
1.10.0  data <id_value>
1.10.1  data <id_value>
2.1.1   open 0x0
[...]
```

5. Assign the data authentication keys to the FIPS drive or SED.

   [Assigning a data authentication key to a FIPS drive or SED (external key management)]

6. If necessary, assign a FIPS 140-2 authentication key to the FIPS drive.

   [Assigning a FIPS 140-2 authentication key to a FIPS drive]

Make data on a FIPS drive or SED inaccessible

Learn about making ONTAP data on a FIPS drive or SED inaccessible

If you want to make data on a FIPS drive or SED permanently inaccessible, but keep the drive's unused space available for new data, you can sanitize the disk. If you want to make data permanently inaccessible and you do not need to reuse the drive, you can destroy it.

- Disk sanitization

  When you sanitize a self-encrypting drive, the system changes the disk encryption key to a new random value, resets the power-on lock state to false, and sets the key ID to a default value, either the manufacturer secure ID 0x0 (SAS drives) or a null key (NVMe drives). Doing so renders the data on the disk inaccessible and impossible to retrieve. You can reuse sanitized disks as non-zeroed spare disks.

- Disk destroy

  When you destroy a FIPS drive or SED, the system sets the disk encryption key to an unknown random value and locks the disk irreversibly. Doing so renders the disk permanently unusable and the data on it permanently inaccessible.

You can sanitize or destroy individual self-encrypting drives, or all the self-encrypting drives for a node.

Sanitize a FIPS drive or SED in ONTAP

If you want to make data on a FIPS drive or SED permanently inaccessible, and use the drive for new data, you can use the `storage encryption disk sanitize` command to sanitize the drive.

About this task

When you sanitize a self-encrypting drive, the system changes the disk encryption key to a new random value, resets the power-on lock state to false, and sets the key ID to a default value, either the manufacturer secure ID 0x0 (SAS drives) or a null key (NVMe drives). Doing so renders the data on the disk inaccessible and impossible to retrieve. You can reuse sanitized disks as non-zeroed spare disks.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Migrate any data that needs to be preserved to an aggregate on another disk.
2. Delete the aggregate on the FIPS drive or SED to be sanitized:

storage aggregate delete -aggregate *aggregate_name*

```
cluster1::> storage aggregate delete -aggregate aggr1
```

Learn more about `storage aggregate delete` in the ONTAP command reference.

3. Identify the disk ID for the FIPS drive or SED to be sanitized:

   `storage encryption disk show -fields data-key-id,fips-key-id,owner`

   Learn more about `storage encryption disk show` in the ONTAP command reference.

```
cluster1::> storage encryption disk show
Disk     Mode Data Key ID
-----    ----
----------------------------------------------------------------
0.0.0    data <id_value>
0.0.1    data <id_value>
1.10.2   data <id_value>
[...]
```

4. If a FIPS drive is running in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID 0x0:

   storage encryption disk modify -disk *disk_id* -fips-key-id 0x0

   You can use the `security key-manager query` command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 1.10.2 -fips-key-id 0x0

Info: Starting modify on 1 disk.
      View the status of the operation by using the
      storage encryption disk show-status command.
```

5. Sanitize the drive:

   storage encryption disk sanitize -disk *disk_id*

   You can use this command to sanitize hot spare or broken disks only. To sanitize all disks regardless of type, use the `-force-all-state` option.
   Learn more about `storage encryption disk sanitize` in the ONTAP command reference.

   ONTAP will prompt you to enter a confirmation phrase before continuing. Enter the phrase exactly as shown on the screen.

```
cluster1::> storage encryption disk sanitize -disk 1.10.2

Warning: This operation will cryptographically sanitize 1 spare or
broken self-encrypting disk on 1 node.
         To continue, enter sanitize disk: sanitize disk

Info: Starting sanitize on 1 disk.
      View the status of the operation using the
      storage encryption disk show-status command.
```

6. Unfail the sanitized disk:
   `storage disk unfail -spare true -disk disk_id`
7. Check whether the disk has an owner:
   `storage disk show -disk disk_id`

   If the disk does not have an owner, assign one.
   `storage disk assign -owner node -disk disk_id`
8. Enter the nodeshell for the node that owns the disks you want to sanitize:

   `system node run -node node_name`

   Run the `disk sanitize release` command.
9. Exit the nodeshell. Unfail the disk again:
   `storage disk unfail -spare true -disk disk_id`
10. Verify that the disk is now a spare and ready to be reused in an aggregate:
   `storage disk show -disk disk_id`

Destroy a FIPS drive or SED in ONTAP

If you want to make data on a FIPS drive or SED permanently inaccessible and you do not need to reuse the drive, you can use the `storage encryption disk destroy` command to destroy the disk.

About this task

When you destroy a FIPS drive or SED, the system sets the disk encryption key to an unknown random value and locks the drive irreversibly. Doing so renders the disk virtually unusable and the data on it permanently inaccessible. However, you can reset the disk to its factory-configured settings using the physical secure ID (PSID) printed on the disk's label. For more information, see Returning a FIPS drive or SED to service when authentication keys are lost.

> You should not destroy a FIPS drive or SED unless you have the Non-Returnable Disk Plus service (NRD Plus). Destroying a disk voids its warranty.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Migrate any data that needs to be preserved to an aggregate on another different disk.
2. Delete the aggregate on the FIPS drive or SED to be destroyed:

   `storage aggregate delete -aggregate aggregate_name`

   ```
   cluster1::> storage aggregate delete -aggregate aggr1
   ```

   Learn more about `storage aggregate delete` in the ONTAP command reference.

3. Identify the disk ID for the FIPS drive or SED to be destroyed:

   `storage encryption disk show`

   Learn more about `storage encryption disk show` in the ONTAP command reference.

   ```
   cluster1::> storage encryption disk show
   Disk     Mode Data Key ID
   -----    ----
   ----------------------------------------------------------------
   0.0.0    data <id_value>
   0.0.1    data <id_value>
   1.10.2   data <id_value>
   [...]
   ```

4. Destroy the disk:

   `storage encryption disk destroy -disk disk_id`

   Learn more about `storage encryption disk destroy` in the ONTAP command reference.

   > You are prompted to enter a confirmation phrase before continuing. Enter the phrase exactly as shown on the screen.

```
cluster1::> storage encryption disk destroy -disk 1.10.2

Warning: This operation will cryptographically destroy 1 spare or broken
         self-encrypting disks on 1 node.
         You cannot reuse destroyed disks unless you revert
         them to their original state using the PSID value.
         To continue, enter
          destroy disk
         :destroy disk

Info: Starting destroy on 1 disk.
      View the status of the operation by using the
      "storage encryption disk show-status" command.
```

Emergency shred data on a FIPS drive or SED in ONTAP

In case of a security emergency, you can instantly prevent access to a FIPS drive or SED, even if power is not available to the storage system or the KMIP server.

Before you begin

- If you are using a KMIP server that has no available power, the KMIP server must be configured with an easily destroyed authentication item (for example, a smart card or USB drive).
- You must be a cluster administrator to perform this task.

Step

1. Perform emergency shredding of data on a FIPS drive or SED:

If…	Then…

<table>
<tr>
<td>Power is available to the storage system and you have time to take the storage system offline gracefully</td>
<td>
a. If the storage system is configured as an HA pair, disable takeover.
b. Take all aggregates offline and delete them.
c. Set the privilege level to advanced:
<code>set -privilege advanced</code>
d. If the drive is in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID:
<code>storage encryption disk modify -disk * -fips-key -id 0x0</code>
e. Halt the storage system.
f. Boot into maintenance mode.
g. Sanitize or destroy the disks:
◦ If you want to make the data on the disks inaccessible and still be able to reuse the disks, sanitize the disks:
<code>disk encrypt sanitize -all</code>
◦ If you want to make the data on the disks inaccessible and you do not need to save the disks, destroy the disks:
<code>disk encrypt destroy disk_id1 disk_id2 …</code>
The <code>disk encrypt sanitize</code> and <code>disk encrypt destroy</code> commands are reserved for maintenance mode only. These commands must be run on each HA node, and are not available for broken disks.
h. Repeat these steps for the partner node.
This leaves the storage system in a permanently disabled state with all data erased. To use the system again, you must reconfigure it.
</td>
</tr>
</table>

<table>
<tr>
<td rowspan="2">Power is available to the storage system and you must shred the data immediately</td>
<td>a. If you want to make the data on the disks inaccessible and still be able to reuse the disks, sanitize the disks:
b. If the storage system is configured as an HA pair, disable takeover.
c. Set the privilege level to advanced:
<code>set -privilege advanced</code>
d. If the drive is in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID:
<code>storage encryption disk modify -disk * -fips-key-id 0x0</code>
e. Sanitize the disk:
<code>storage encryption disk sanitize -disk * -force-all-states true</code></td>
<td>a. If you want to make the data on the disks inaccessible and you do not need to save the disks, destroy the disks:
b. If the storage system is configured as an HA pair, disable takeover.
c. Set the privilege level to advanced:
<code>set -privilege advanced</code>
d. Destroy the disks:
<code>storage encryption disk destroy -disk * -force-all-states true</code></td>
</tr>
<tr>
<td colspan="2">The storage system panics, leaving the system in a permanently disabled state with all data erased. To use the system again, you must reconfigure it.</td>
</tr>
<tr>
<td>Power is available to the KMIP server but not to the storage system</td>
<td colspan="2">a. Log in to the KMIP server.
b. Destroy all keys associated with the FIPS drives or SEDs that contain the data you want to prevent access to.
This prevents access to disk encryption keys by the storage system.</td>
</tr>
<tr>
<td>Power is not available to the KMIP server or the storage system</td>
<td colspan="2">Destroy the authentication item for the KMIP server (for example, the smart card). This prevents access to disk encryption keys by the storage system.</td>
</tr>
</table>

Learn more about the commands described in this procedure in the ONTAP command reference.

Return a FIPS drive or SED to service when authentication keys are lost in ONTAP

The system treats a FIPS drive or SED as broken if you lose the authentication keys for it permanently and cannot retrieve them from the KMIP server. Although you cannot access or recover the data on the disk, you can take steps to make the SED's unused space available again for data.

Before you begin

You must be a cluster administrator to perform this task.

About this task

You should use this process only if you are certain that the authentication keys for the FIPS drive or SED are permanently lost and that you cannot recover them.

If the disks are partitioned, they must first be unpartitioned before you can start this process.

> The command to unpartition a disk is only available at the diag level and should be performed only under NetApp Support supervision. **It is highly recommended that you contact NetApp Support before you proceed.** You can also refer to the Knowledge Base article How to unpartition a spare drive in ONTAP.

Steps

1. Return a FIPS drive or SED to service:

If the SEDS are…	Use these steps…

<table>
<tr>
<td>Not in FIPS-compliance mode, or in FIPS-compliance mode and the FIPS key is available</td>
<td>
a. Set the privilege level to advanced:
<code>set -privilege advanced</code>

b. Reset the FIPS key to the default manufacture secure ID 0x0:
<code>storage encryption disk modify -fips-key-id 0x0 -disk disk_id</code>

c. Verify the operation succeeded:
<code>storage encryption disk show-status</code>
If the operation failed, use the PSID process in this topic.

d. Sanitize the broken disk:
<code>storage encryption disk sanitize -disk disk_id</code>
Verify the operation succeeded with the command <code>storage encryption disk show-status</code> before proceeding to the next step.

e. Unfail the sanitized disk:
<code>storage disk unfail -spare true -disk disk_id</code>

f. Check whether the disk has an owner:
<code>storage disk show -disk disk_id</code>

If the disk does not have an owner, assign one.
<code>storage disk assign -owner node -disk disk_id</code>

1. Enter the nodeshell for the node that owns the disks you want to sanitize:

<code>system node run -node node_name</code>

Run the <code>disk sanitize release</code> command.

g. Exit the nodeshell. Unfail the disk again:
<code>storage disk unfail -spare true -disk disk_id</code>

h. Verify that the disk is now a spare and ready to be reused in an aggregate:
<code>storage disk show -disk disk_id</code>
</td>
</tr>
</table>

In FIPS-compliance mode, the FIPS key is not available, and the SEDs have a PSID printed on the label	a. Obtain the PSID of the disk from the disk label. b. Set the privilege level to advanced: `set -privilege advanced` c. Reset the disk to its factory-configured settings: `storage encryption disk revert-to-original-state -disk` *`disk_id`* `-psid` *`disk_physical_secure_id`* Verify the operation succeeded with the command `storage encryption disk show-status` before proceeding to the next step. d. If you are running ONTAP 9.8P5 or earlier, skip to the next step. If you are running ONTAP 9.8P6 or later, unfail the sanitized disk. `storage disk unfail -disk` *`disk_id`* e. Check whether the disk has an owner: `storage disk show -disk` *`disk_id`* If the disk does not have an owner, assign one. `storage disk assign -owner node -disk` *`disk_id`* 1. Enter the nodeshell for the node that owns the disks you want to sanitize: `system node run -node` *`node_name`* Run the `disk sanitize release` command. f. Exit the nodeshell.. Unfail the disk again: `storage disk unfail -spare true -disk` *`disk_id`* g. Verify that the disk is now a spare and ready to be reused in an aggregate: `storage disk show -disk` *`disk_id`*

Learn more about the commands described in this procedure in the ONTAP command reference.

Return a FIPS drive or SED to unprotected mode in ONTAP

A FIPS drive or SED is protected from unauthorized access only if the authentication key ID for the node is set to a value other than the default. You can return a FIPS drive or SED to unprotected mode by using the `storage encryption disk modify` command to set the key ID to the default. A FIPS drive or SED in unprotected mode uses the default encryption keys, while a FIPS drive or SED in protected mode uses supplied, secret encryption keys. If there is encrypted data on the drive and the drive is reset to unprotected mode, the data is still encrypted and is not exposed.

> ⓘ Follow this procedure to ensure that any encrypted data becomes inaccessible after the FIPS drive or SED is returned to unprotected mode. Once the FIPS and data key IDs are reset, any existing data can not be decrypted and becomes inaccessible.

If an HA pair is using encrypting SAS or NVMe drives (SED, NSE, FIPS), you must follow this process for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Set the privilege level to advanced:

   `set -privilege advanced`

2. If a FIPS drive is running in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID 0x0:

   `storage encryption disk modify -disk disk_id -fips-key-id 0x0`

   You can use the `security key-manager query` command to view key IDs.

   ```
   cluster1::> storage encryption disk modify -disk 2.10.11 -fips-key-id
   0x0

   Info: Starting modify on 14 disks.
         View the status of the operation by using the
         storage encryption disk show-status command.
   ```

   Confirm the operation succeeded with the command:

   `storage encryption disk show-status`

   Repeat the show-status command until the numbers in “Disks Begun” and “Disks Done” are the same.

   ```
   cluster1:: storage encryption disk show-status

               FIPS    Latest   Start               Execution   Disks
   Disks Disks
   Node        Support Request  Timestamp           Time (sec)  Begun
   Done  Successful
   -------     ------- -------- ------------------  ---------- ------
   ------  ----------
   cluster1    true    modify   1/18/2022 15:29:38    3           14     5
   5
   1 entry was displayed.
   ```

3. Set the data authentication key ID for the node back to the default MSID 0x0:

   `storage encryption disk modify -disk disk_id -data-key-id 0x0`

   The value of `-data-key-id` should be set to 0x0 whether you are returning a SAS or NVMe drive to unprotected mode.

You can use the `security key-manager query` command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 2.10.11 -data-key-id
0x0

Info: Starting modify on 14 disks.
      View the status of the operation by using the
      storage encryption disk show-status command.
```

Confirm the operation succeeded with the command:

`storage encryption disk show-status`

Repeat the show-status command until the numbers are the same. The operation is complete when the numbers in “disks begun” and “disks done” are the same.

Maintenance mode

Beginning with ONTAP 9.7, you can rekey a FIPS drive from maintenance mode. You should only use maintenance mode if you cannot use the ONTAP CLI instructions in the earlier section.

Steps

1. Set the FIPS authentication key ID for the node back to the default MSID 0x0:

   `disk encrypt rekey_fips 0x0` *`disklist`*

2. Set the data authentication key ID for the node back to the default MSID 0x0:

   `disk encrypt rekey 0x0` *`disklist`*

3. Confirm the FIPS authentication key was successfully rekeyed:

   `disk encrypt show_fips`

4. Confirm data authentication key was successfully rekeyed with:

   `disk encrypt show`

   Your output will likely display either the default MSID 0x0 key ID or the 64-character value held by the key server. The `Locked?` field refers to data-locking.

```
Disk       FIPS Key ID                 Locked?
---------- --------------------------- -------
0a.01.0    0x0                          Yes
```

Remove an external key manager connection in ONTAP

You can disconnect a KMIP server from a node when you no longer need the server. For example, you might disconnect a KMIP server when you are transitioning to volume encryption.

About this task

When you disconnect a KMIP server from one node in an HA pair, the system automatically disconnects the server from all cluster nodes.

> If you plan to continue using external key management after disconnecting a KMIP server, make sure another KMIP server is available to serve authentication keys.

Before you begin

You must be a cluster or SVM administrator to perform this task.

Step

1. Disconnect a KMIP server from the current node:

For this ONTAP version…	Use this command…
ONTAP 9.6 and later	`security key-manager external remove-servers -vserver SVM -key-servers host_name|IP_address:port,…`
ONTAP 9.5 and earlier	`security key-manager delete -address key_management_server_ipaddress`

In a MetroCluster environment, you must repeat these commands on both clusters for the admin SVM.

The following ONTAP 9.6 command disables the connections to two external key management servers for `cluster1`, the first named `ks1`, listening on the default port 5696, the second with the IP address 10.0.0.20, listening on port 24482:

```
cluster1::> security key-manager external remove-servers -vserver
cluster-1 -key-servers ks1,10.0.0.20:24482
```

Learn more about `security key-manager external remove-servers` and `security key-manager delete` in the ONTAP command reference.

Modify ONTAP external key management server properties

Beginning with ONTAP 9.6, you can use the `security key-manager external modify-server` command to change the I/O timeout and user name of an external key management server.

Before you begin

- You must be a cluster or SVM administrator to perform this task.
- Advanced privileges are required for this task.
- In a MetroCluster environment, you must repeat these steps on both clusters for the admin SVM.

Steps

1. On the storage system, change to advanced privilege level:

   `set -privilege advanced`

2. Modify external key manager server properties for the cluster:

   `security key-manager external modify-server -vserver admin_SVM -key-server host_name|IP_address:port,… -timeout 1…60 -username user_name`

   > The timeout value is expressed in seconds. If you modify the user name, you are prompted to enter a new password. If you run the command at the cluster login prompt, *`admin_SVM`* defaults to the admin SVM of the current cluster. You must be the cluster administrator to modify external key manager server properties.

   The following command changes the timeout value to 45 seconds for the `cluster1` external key management server listening on the default port 5696:

   ```
   clusterl::> security key-manager external modify-server -vserver
   cluster1 -key-server ks1.local -timeout 45
   ```

3. Modify external key manager server properties for an SVM (NVE only):

   `security key-manager external modify-server -vserver SVM -key-server host_name|IP_address:port,… -timeout 1…60 -username user_name`

   > The timeout value is expressed in seconds. If you modify the user name, you are prompted to enter a new password. If you run the command at the SVM login prompt, *`SVM`* defaults to the current SVM. You must be the cluster or SVM administrator to modify external key manager server properties.

   The following command changes the username and password of the `svm1` external key management server listening on the default port 5696:

   ```
   svml::> security key-manager external modify-server -vserver svm11 -key
   -server ks1.local -username svm1user
   Enter the password:
   Reenter the password:
   ```

4. Repeat the last step for any additional SVMs.

- security key-manager external modify-server

Transition to external key management from onboard key management in ONTAP

If you want to switch to external key management from onboard key management, you must delete the onboard key management configuration before you can enable external key management.

Before you begin

- For hardware-based encryption, you must reset the data keys of all FIPS drives or SEDs to the default value.

  Returning a FIPS drive or SED to unprotected mode

- For software-based encryption, you must unencrypt all volumes.

  Unencrypting volume data

- You must be a cluster administrator to perform this task.

Step

1. Delete the onboard key management configuration for a cluster:

For this ONTAP version…	Use this command…
ONTAP 9.6 and later	`security key-manager onboard disable -vserver SVM`
ONTAP 9.5 and earlier	`security key-manager delete-key-database`

   Learn more about `security key-manager onboard disable` and `security key-manager delete-key-database` in the ONTAP command reference.

Transition from external key management to ONTAP onboard key management

If you want to switch to onboard key management from external key management, you must delete the external key management configuration before you can enable onboard key management.

Before you begin

- For hardware-based encryption, you must reset the data keys of all FIPS drives or SEDs to the default value.

  Returning a FIPS drive or SED to unprotected mode

- You must have deleted all external key manager connections.

  Deleting an external key manager connection

- You must be a cluster administrator to perform this task.

Steps

The steps to transition your key management depend on the version of ONTAP you are using.

ONTAP 9.6 and later

1. Change to the advanced privilege level:

   `set -privilege advanced`

2. Use the command:

   `security key-manager external disable -vserver admin_SVM`

   In a MetroCluster environment, you must repeat the command on both clusters for the admin SVM.

ONTAP 9.5 and earlier

Use the command:
`security key-manager delete-kmip-config`

Learn more about `security key-manager delete-kmip-config` in the ONTAP command reference.

What happens when key management servers are not reachable during the ONTAP boot process

ONTAP takes certain precautions to avoid undesired behavior in the event that a storage system configured for NSE cannot reach any of the specified key management servers during the boot process.

If the storage system is configured for NSE, the SEDs are rekeyed and locked, and the SEDs are powered on, the storage system must retrieve the required authentication keys from the key management servers to authenticate itself to the SEDs before it can access the data.

The storage system attempts to contact the specified key management servers for up to three hours. If the storage system cannot reach any of them after that time, the boot process stops and the storage system halts.

If the storage system successfully contacts any specified key management server, it then attempts to establish an SSL connection for up to 15 minutes. If the storage system cannot establish an SSL connection with any specified key management server, the boot process stops and the storage system halts.

While the storage system attempts to contact and connect to key management servers, it displays detailed information about the failed contact attempts at the CLI. You can interrupt the contact attempts at any time by pressing Ctrl-C.

As a security measure, SEDs allow only a limited number of unauthorized access attempts, after which they disable access to the existing data. If the storage system cannot contact any specified key management servers to obtain the proper authentication keys, it can only attempt to authenticate with the default key which leads to a failed attempt and a panic. If the storage system is configured to automatically reboot in case of a panic, it enters a boot loop which results in continuous failed authentication attempts on the SEDs.

Halting the storage system in these scenarios is by design to prevent the storage system from entering a boot loop and possible unintended data loss as a result of the SEDs locked permanently due to exceeding the safety limit of a certain number of consecutive failed authentication attempts. The limit and the type of lockout protection depends on the manufacturing specifications and type of SED:

SED type	Number of consecutive failed authentication attempts resulting in lockout	Lockout protection type when safety limit is reached
HDD	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
X440_PHM2800MCTO 800GB NSE SSDs with firmware revisions NA00 or NA01	5	Temporary. Lockout is only in effect until disk is power-cycled.
X577_PHM2800MCTO 800GB NSE SSDs with firmware revisions NA00 or NA01	5	Temporary. Lockout is only in effect until disk is power-cycled.
X440_PHM2800MCTO 800GB NSE SSDs with higher firmware revisions	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
X577_PHM2800MCTO 800GB NSE SSDs with higher firmware revisions	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
All other SSD models	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.

For all SED types, a successful authentication resets the try count to zero.

If you encounter this scenario where the storage system is halted due to failure to reach any specified key management servers, you must first identify and correct the cause for the communication failure before you attempt to continue booting the storage system.

Disable ONTAP encryption by default

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager. If necessary, you can disable encryption by default for the entire cluster.

Before you begin

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

Step

1. To disable encryption by default for the entire cluster in ONTAP 9.7 or later, run the following command:

```
options -option-name encryption.data_at_rest_encryption.disable_by_default
-option-value on
```

Data protection and disaster recovery

Cluster and SVM peering

Learn about ONTAP cluster and SVM peering

You can create peer relationships between source and destination clusters and between source and destination storage virtual machines (SVMs). You must create peer relationships between these entities before you can replicate snapshots using SnapMirror.

ONTAP 9.3 offers enhancements that simplify the way you configure peer relationships between clusters and SVMs. The cluster and SVMs peering procedures are available for all ONTAP 9 versions. You should use the appropriate procedure for your version of ONTAP.

You perform the procedures using the command-line interface (CLI), not System Manager or an automated scripting tool.

Prepare for cluster and SVM peering

ONTAP peering basics

You must create *peer relationships* between source and destination clusters and between source and destination SVMs before you can replicate snapshots using SnapMirror. A peer relationship defines network connections that enable clusters and SVMs to exchange data securely.

Clusters and SVMs in peer relationships communicate over the intercluster network using *intercluster logical interfaces (LIFs).* An intercluster LIF is a LIF that supports the "intercluster-core" network interface service and is typically created using the "default-intercluster" network interface service policy. You must create intercluster LIFs on every node in the clusters being peered.

Intercluster LIFs use routes that belong to the system SVM to which they are assigned. ONTAP automatically creates a system SVM for cluster-level communications within an IPspace.

Fan-out and cascade topologies are both supported. In a cascade topology, you need only create intercluster networks between the primary and secondary clusters and between the secondary and tertiary clusters. You need not create an intercluster network between the primary and the tertiary cluster.

> It is possible (but not advisable) for an administrator to remove the intercluster-core service from the default-intercluster service policy. If this occurs, LIFs created using "default-intercluster" will not actually be intercluster LIFs. To confirm that the default-intercluster service policy contains the intercluster-core service, use the following command:
>
> ```
> network interface service-policy show -policy default-intercluster
> ```
>
> Learn more about `network interface service-policy show` in the ONTAP command reference.

ONTAP peering prerequisites

Before you set up cluster peering, you should confirm that the connectivity, port, IP address, subnet, firewall, and cluster-naming requirements are met.

> Beginning with ONTAP 9.6, Cluster Peering provides TLS 1.2 AES-256 GCM encryption support for data replication by default. The default security ciphers ("PSK-AES256-GCM-SHA384") are required for Cluster Peering to work even if encryption is disabled.
>
> Beginning with ONTAP 9.11.1, DHE-PSK security ciphers are available by default.
>
> Beginning with ONTAP 9.15.1, Cluster Peering provides TLS 1.3 encryption support for data replication by default.

Connectivity requirements

Every intercluster LIF on the local cluster must be able to communicate with every intercluster LIF on the remote cluster.

Although it is not required, it is typically simpler to configure the IP addresses used for intercluster LIFs in the same subnet. The IP addresses can reside in the same subnet as data LIFs, or in a different subnet. The subnet used in each cluster must meet the following requirements:

- The subnet must belong to the broadcast domain that contains the ports that are used for intercluster communication.
- The subnet must have enough IP addresses available to allocate to one intercluster LIF per node.

  For example, in a four-node cluster, the subnet used for intercluster communication must have four available IP addresses.

Each node must have an intercluster LIF with an IP address on the intercluster network.

Intercluster LIFs can have an IPv4 address or an IPv6 address.

> ONTAP enables you to migrate your peering networks from IPv4 to IPv6 by optionally allowing both protocols to be present simultaneously on the intercluster LIFs. In earlier releases, all intercluster relationships for an entire cluster were either IPv4 or IPv6. This meant that changing protocols was a potentially disruptive event.

Port requirements

You can use dedicated ports for intercluster communication, or share ports used by the data network. Ports must meet the following requirements:

- All ports that are used to communicate with a given remote cluster must be in the same IPspace.

  You can use multiple IPspaces to peer with multiple clusters. Pair-wise full-mesh connectivity is required only within an IPspace.

- The broadcast domain that is used for intercluster communication must include at least two ports per node so that intercluster communication can fail over from one port to another port.

  Ports added to a broadcast domain can be physical network ports, VLANs, or interface groups (ifgrps).

* All ports must be cabled.
* All ports must be in a healthy state.
* The MTU settings of the ports must be consistent.

Firewall requirements

> Beginning with ONTAP 9.10.1, firewall policies are deprecated and wholly replaced with LIF service policies. For more information, see Configure firewall policies for LIFs.

Firewalls and the intercluster firewall policy must allow the following protocols:

* Bidirectional ICMP traffic
* Bidirectional initiated TCP traffic to the IP addresses of all the intercluster LIFs over ports 11104 and 11105
* Bidirectional HTTPS between the intercluster LIFs

  Although HTTPS is not required when you set up cluster peering using the CLI, HTTPS is required later if you use System Manager to configure data protection.

The default `intercluster` firewall policy allows access through the HTTPS protocol and from all IP addresses (0.0.0.0/0). You can modify or replace the policy if necessary.

Cluster requirement

Clusters must meet the following requirement:

* A cluster cannot be in a peer relationship with more than 255 clusters.

Use shared or dedicated ONTAP ports

You can use dedicated ports for intercluster communication, or share ports used by the data network. In deciding whether to share ports, you need to consider network bandwidth, the replication interval, and port availability.

> You can share ports on one peered cluster while using dedicated ports on the other.

Network bandwidth

If you have a high-speed network, such as 10 GbE, you might have enough local LAN bandwidth to perform replication using the same 10 GbE ports used for data access.

Even then, you should compare your available WAN bandwidth to your LAN bandwidth. If the available WAN bandwidth is significantly less than 10 GbE, you might need to use dedicated ports.

> The one exception to this rule might be when all or many nodes in the cluster replicate data, in which case bandwidth utilization is typically spread across nodes.

If you are not using dedicated ports, the maximum transmission unit (MTU) size of the replication network should typically be the same as the MTU size of the data network.

Replication interval

If replication takes place in off-peak hours, you should be able to use data ports for replication even without a 10-GbE LAN connection.

If replication takes place during normal business hours, you need to consider the amount of data that will be replicated and whether it requires so much bandwidth that it could cause contention with data protocols. If network utilization by data protocols (SMB, NFS, iSCSI) is above 50%, you should use dedicated ports for intercluster communication, to allow for non-degraded performance if node failover occurs.

Port availability

If you determine that replication traffic is interfering with data traffic, you can migrate intercluster LIFs to any other intercluster-capable shared port on the same node.

You can also dedicate VLAN ports for replication. The bandwidth of the port is shared between all VLANs and the base port.

Use custom ONTAP IPspaces to isolate replication traffic

You can use custom IPspaces to separate the interactions that a cluster has with its peers. Called *designated intercluster connectivity*, this configuration allows service providers to isolate replication traffic in multitenant environments.

Suppose, for example, that you want replication traffic between Cluster A and Cluster B to be separated from replication traffic between Cluster A and Cluster C. To accomplish this, you can create two IPspaces on Cluster A.

One IPspace contains the intercluster LIFs that you use to communicate with Cluster B. The other contains the intercluster LIFs that you use to communicate with Cluster C, as shown in the following illustration.

Configure intercluster LIFs

Configure ONTAP intercluster LIFs on shared data ports

You can configure intercluster LIFs on ports shared with the data network. Doing so reduces the number of ports you need for intercluster networking.

Steps

1. List the ports in the cluster:

   `network port show`

   Learn more about `network port show` in the ONTAP command reference.

   The following example shows the network ports in `cluster01`:

```
cluster01::> network port show
                                                             Speed
(Mbps)
Node   Port      IPspace      Broadcast Domain Link   MTU    Admin/Oper
------ --------- ------------ ---------------- ----- -------
------------
cluster01-01
       e0a       Cluster      Cluster          up     1500   auto/1000
       e0b       Cluster      Cluster          up     1500   auto/1000
       e0c       Default      Default          up     1500   auto/1000
       e0d       Default      Default          up     1500   auto/1000
cluster01-02
       e0a       Cluster      Cluster          up     1500   auto/1000
       e0b       Cluster      Cluster          up     1500   auto/1000
       e0c       Default      Default          up     1500   auto/1000
       e0d       Default      Default          up     1500   auto/1000
```

2. Create intercluster LIFs on either an admin SVM (Default IPspace) or a system SVM (custom IPspace):

Option	Description
In ONTAP 9.6 and later:	`network interface create -vserver` *`system_SVM`* `-lif` *`LIF_name`* `-service -policy default-intercluster -home -node` *`node`* `-home-port port -address` *`port_IP`* `-netmask` *`netmask`*

Option	Description
In ONTAP 9.5 and earlier:	`network interface create -vserver` *`system_SVM`* `-lif` *`LIF_name`* `-role intercluster -home-node` *`node`* `-home -port` *`port`* `-address` *`port_IP`* `-netmask` *`netmask`*

Learn more about `network interface create` in the ONTAP command reference.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02`:

```
cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0c
-address 192.168.1.201
-netmask 255.255.255.0

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0c
-address 192.168.1.202
-netmask 255.255.255.0
```

3. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	`network interface show -service-policy default-intercluster`
In ONTAP 9.5 and earlier:	`network interface show -role intercluster`

Learn more about `network interface show` in the ONTAP command reference.

```
cluster01::> network interface show -service-policy default-intercluster
            Logical    Status     Network            Current
Current Is
Vserver     Interface  Admin/Oper Address/Mask       Node          Port
Home
----------- ---------- ---------- ------------------ -------------
------- ----
cluster01
            cluster01_icl01
                       up/up      192.168.1.201/24   cluster01-01  e0c
true
            cluster01_icl02
                       up/up      192.168.1.202/24   cluster01-02  e0c
true
```

4. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	`network interface show –service-policy default-intercluster -failover`
In ONTAP 9.5 and earlier:	`network interface show -role intercluster -failover`

Learn more about `network interface show` in the ONTAP command reference.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the `e0c` port will fail over to the `e0d` port.

```
cluster01::> network interface show -service-policy default-intercluster
–failover
         Logical         Home                  Failover        Failover
Vserver  Interface       Node:Port             Policy          Group
-------- --------------- --------------------- --------------- --------
cluster01
         cluster01_icl01 cluster01-01:e0c   local-only
192.168.1.201/24
                            Failover Targets: cluster01-01:e0c,
                                              cluster01-01:e0d
         cluster01_icl02 cluster01-02:e0c   local-only
192.168.1.201/24
                            Failover Targets: cluster01-02:e0c,
                                              cluster01-02:e0d
```

Configure ONTAP intercluster LIFs on dedicated ports

You can configure intercluster LIFs on dedicated ports. Doing so typically increases the available bandwidth for replication traffic.

Steps

1. List the ports in the cluster:

   `network port show`

   Learn more about `network port show` in the ONTAP command reference.

   The following example shows the network ports in `cluster01`:

```
cluster01::> network port show
                                                             Speed
(Mbps)
Node   Port      IPspace      Broadcast Domain Link   MTU    Admin/Oper
------ --------- ------------ ---------------- ----- -------
------------
cluster01-01
       e0a       Cluster      Cluster          up     1500   auto/1000
       e0b       Cluster      Cluster          up     1500   auto/1000
       e0c       Default      Default          up     1500   auto/1000
       e0d       Default      Default          up     1500   auto/1000
       e0e       Default      Default          up     1500   auto/1000
       e0f       Default      Default          up     1500   auto/1000
cluster01-02
       e0a       Cluster      Cluster          up     1500   auto/1000
       e0b       Cluster      Cluster          up     1500   auto/1000
       e0c       Default      Default          up     1500   auto/1000
       e0d       Default      Default          up     1500   auto/1000
       e0e       Default      Default          up     1500   auto/1000
       e0f       Default      Default          up     1500   auto/1000
```

2. Determine which ports are available to dedicate to intercluster communication:

   `network interface show -fields home-port,curr-port`

   Learn more about `network interface show` in the ONTAP command reference.

   The following example shows that ports `e0e` and `e0f` have not been assigned LIFs:

```
cluster01::> network interface show -fields home-port,curr-port
vserver lif                  home-port curr-port
------- -------------------- --------- ---------
Cluster cluster01-01_clus1   e0a       e0a
Cluster cluster01-01_clus2   e0b       e0b
Cluster cluster01-02_clus1   e0a       e0a
Cluster cluster01-02_clus2   e0b       e0b
cluster01
        cluster_mgmt         e0c       e0c
cluster01
        cluster01-01_mgmt1   e0c       e0c
cluster01
        cluster01-02_mgmt1   e0c       e0c
```

3. Create a failover group for the dedicated ports:

   `network interface failover-groups create -vserver` *`system_SVM`* `-failover-group` *`failover_group`* `-targets` *`physical _or_logical_ports`*

   The following example assigns ports `e0e` and `e0f` to the failover group `intercluster01` on the system SVM `cluster01`:

```
cluster01::> network interface failover-groups create -vserver cluster01
-failover-group
intercluster01 -targets
cluster01-01:e0e,cluster01-01:e0f,cluster01-02:e0e,cluster01-02:e0f
```

4. Verify that the failover group was created:

   `network interface failover-groups show`

   Learn more about `network interface failover-groups show` in the ONTAP command reference.

```
cluster01::> network interface failover-groups show
                                  Failover
Vserver          Group            Targets
---------------- ----------------
--------------------------------------------
Cluster
                 Cluster
                                  cluster01-01:e0a, cluster01-01:e0b,
                                  cluster01-02:e0a, cluster01-02:e0b
cluster01
                 Default
                                  cluster01-01:e0c, cluster01-01:e0d,
                                  cluster01-02:e0c, cluster01-02:e0d,
                                  cluster01-01:e0e, cluster01-01:e0f
                                  cluster01-02:e0e, cluster01-02:e0f
                 intercluster01
                                  cluster01-01:e0e, cluster01-01:e0f
                                  cluster01-02:e0e, cluster01-02:e0f
```

5. Create intercluster LIFs on the system SVM and assign them to the failover group.

Option	Description
In ONTAP 9.6 and later:	`network interface create -vserver` *`system_SVM`* `-lif` *`LIF_name`* `-service -policy default-intercluster -home -node` *`node`* `-home- port` *`port`* `-address` *`port_IP`* `-netmask` *`netmask`* `-failover -group` *`failover_group`*
In ONTAP 9.5 and earlier:	`network interface create -vserver` *`system_SVM`* `-lif` *`LIF_name`* `-role intercluster -home-node` *`node`* `-home -port` *`port`* `-address` *`port_IP`* `-netmask` *`netmask`* `-failover-group` *`failover_group`*

Learn more about `network interface create` in the ONTAP command reference.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02` in the failover group `intercluster01`:

```
cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0e
-address 192.168.1.201
-netmask 255.255.255.0 -failover-group intercluster01

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0e
-address 192.168.1.202
-netmask 255.255.255.0 -failover-group intercluster01
```

6. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	`network interface show -service-policy default-intercluster`
In ONTAP 9.5 and earlier:	`network interface show -role intercluster`

Learn more about `network interface show` in the ONTAP command reference.

```
cluster01::> network interface show -service-policy default-intercluster
            Logical    Status     Network            Current
Current Is
Vserver     Interface  Admin/Oper Address/Mask       Node          Port
Home
----------- ---------- ---------- ------------------ -------------
------- ----
cluster01
            cluster01_icl01
                       up/up      192.168.1.201/24   cluster01-01  e0e
true
            cluster01_icl02
                       up/up      192.168.1.202/24   cluster01-02  e0f
true
```

7. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	`network interface show -service-policy default-intercluster -failover`
In ONTAP 9.5 and earlier:	`network interface show -role intercluster -failover`

Learn more about `network interface show` in the ONTAP command reference.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the SVM`e0e` port will fail over to the `e0f` port.

```
cluster01::> network interface show -service-policy default-intercluster
-failover
         Logical         Home                  Failover        Failover
Vserver  Interface       Node:Port             Policy          Group

```

Configure ONTAP intercluster LIFs in custom IPspaces

You can configure intercluster LIFs in custom IPspaces. Doing so allows you to isolate replication traffic in multitenant environments.

When you create a custom IPspace, the system creates a system storage virtual machine (SVM) to serve as a container for the system objects in that IPspace. You can use the new SVM as the container for any intercluster LIFs in the new IPspace. The new SVM has the same name as the custom IPspace.

Steps

1. List the ports in the cluster:

   `network port show`

   Learn more about `network port show` in the ONTAP command reference.

   The following example shows the network ports in `cluster01`:

```
cluster01::> network port show
                                                                    Speed
(Mbps)
Node   Port      IPspace      Broadcast Domain Link   MTU    Admin/Oper
------ --------- ------------ ---------------- ----- -------
------------
cluster01-01
       e0a       Cluster      Cluster          up     1500   auto/1000
       e0b       Cluster      Cluster          up     1500   auto/1000
       e0c       Default      Default          up     1500   auto/1000
       e0d       Default      Default          up     1500   auto/1000
       e0e       Default      Default          up     1500   auto/1000
       e0f       Default      Default          up     1500   auto/1000
cluster01-02
       e0a       Cluster      Cluster          up     1500   auto/1000
       e0b       Cluster      Cluster          up     1500   auto/1000
       e0c       Default      Default          up     1500   auto/1000
       e0d       Default      Default          up     1500   auto/1000
       e0e       Default      Default          up     1500   auto/1000
       e0f       Default      Default          up     1500   auto/1000
```

2. Create custom IPspaces on the cluster:

   `network ipspace create -ipspace` *`ipspace`*

   The following example creates the custom IPspace `ipspace-IC1`:

```
cluster01::> network ipspace create -ipspace ipspace-IC1
```

   Learn more about `network ipspace create` in the ONTAP command reference.

3. Determine which ports are available to dedicate to intercluster communication:

   `network interface show -fields home-port,curr-port`

   Learn more about `network interface show` in the ONTAP command reference.

   The following example shows that ports `e0e` and `e0f` have not been assigned LIFs:

```
cluster01::> network interface show -fields home-port,curr-port
vserver lif                  home-port curr-port
------- -------------------- --------- ---------
Cluster cluster01_clus1   e0a       e0a
Cluster cluster01_clus2   e0b       e0b
Cluster cluster02_clus1   e0a       e0a
Cluster cluster02_clus2   e0b       e0b
cluster01
        cluster_mgmt         e0c       e0c
cluster01
        cluster01-01_mgmt1   e0c       e0c
cluster01
        cluster01-02_mgmt1   e0c       e0c
```

4. Remove the available ports from the default broadcast domain:

   `network port broadcast-domain remove-ports -broadcast-domain Default -ports ports`

   A port cannot be in more than one broadcast domain at a time.
   Learn more about `network port broadcast-domain remove-ports` in the ONTAP command reference.

   The following example removes ports `e0e` and `e0f` from the default broadcast domain:

```
cluster01::> network port broadcast-domain remove-ports -broadcast
-domain Default -ports
cluster01-01:e0e,cluster01-01:e0f,cluster01-02:e0e,cluster01-02:e0f
```

5. Verify that the ports have been removed from the default broadcast domain:

   `network port show`

   Learn more about `network port show` in the ONTAP command reference.

   The following example shows that ports `e0e` and `e0f` have been removed from the default broadcast domain:

```
cluster01::> network port show
                                                       Speed (Mbps)
Node   Port    IPspace   Broadcast Domain Link   MTU    Admin/Oper
------ ------- --------- ---------------- ----- ------- ------------
cluster01-01
       e0a     Cluster    Cluster          up    9000   auto/1000
       e0b     Cluster    Cluster          up    9000   auto/1000
       e0c     Default    Default          up    1500   auto/1000
       e0d     Default    Default          up    1500   auto/1000
       e0e     Default    -                up    1500   auto/1000
       e0f     Default    -                up    1500   auto/1000
       e0g     Default    Default          up    1500   auto/1000
cluster01-02
       e0a     Cluster    Cluster          up    9000   auto/1000
       e0b     Cluster    Cluster          up    9000   auto/1000
       e0c     Default    Default          up    1500   auto/1000
       e0d     Default    Default          up    1500   auto/1000
       e0e     Default    -                up    1500   auto/1000
       e0f     Default    -                up    1500   auto/1000
       e0g     Default    Default          up    1500   auto/1000
```

6. Create a broadcast domain in the custom IPspace:

   `network port broadcast-domain create -ipspace` *`ipspace`* `-broadcast-domain` *`broadcast_domain`* `-mtu` *`MTU`* `-ports` *`ports`*

   The following example creates the broadcast domain `ipspace-IC1-bd` in the IPspace `ipspace-IC1`:

```
cluster01::> network port broadcast-domain create -ipspace ipspace-IC1
-broadcast-domain
ipspace-IC1-bd -mtu 1500 -ports cluster01-01:e0e,cluster01-01:e0f,
cluster01-02:e0e,cluster01-02:e0f
```

7. Verify that the broadcast domain was created:

   `network port broadcast-domain show`

   Learn more about `network port broadcast-domain show` in the ONTAP command reference.

```
cluster01::> network port broadcast-domain show
IPspace Broadcast                                         Update
Name    Domain Name    MTU  Port List                     Status Details
------- ----------- ------  ----------------------------- --------------
Cluster Cluster       9000
                            cluster01-01:e0a              complete
                            cluster01-01:e0b              complete
                            cluster01-02:e0a              complete
                            cluster01-02:e0b              complete
Default Default       1500
                            cluster01-01:e0c              complete
                            cluster01-01:e0d              complete
                            cluster01-01:e0f              complete
                            cluster01-01:e0g              complete
                            cluster01-02:e0c              complete
                            cluster01-02:e0d              complete
                            cluster01-02:e0f              complete
                            cluster01-02:e0g              complete
ipspace-IC1
        ipspace-IC1-bd
                      1500
                            cluster01-01:e0e              complete
                            cluster01-01:e0f              complete
                            cluster01-02:e0e              complete
                            cluster01-02:e0f              complete
```

8. Create intercluster LIFs on the system SVM and assign them to the broadcast domain:

Option	Description
In ONTAP 9.6 and later:	`network interface create -vserver` *`system_SVM`* `-lif` *`LIF_name`* `-service -policy default-intercluster -home -node` *`node`* `-home-port` *`port`* `-address` *`port_IP`* `-netmask` *`netmask`*
In ONTAP 9.5 and earlier:	`network interface create -vserver` *`system_SVM`* `-lif` *`LIF_name`* `-role intercluster -home-node` *`node`* `-home -port` *`port`* `-address` *`port_IP`* `-netmask` *`netmask`*

The LIF is created in the broadcast domain that the home port is assigned to. The broadcast domain has a default failover group with the same name as the broadcast domain.
Learn more about `network interface create` in the ONTAP command reference.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02` in the broadcast domain `ipspace-IC1-bd`:

```
cluster01::> network interface create -vserver ipspace-IC1 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0e
-address 192.168.1.201
-netmask 255.255.255.0

cluster01::> network interface create -vserver ipspace-IC1 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0e
-address 192.168.1.202
-netmask 255.255.255.0
```

9. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	`network interface show -service-policy default-intercluster`
In ONTAP 9.5 and earlier:	`network interface show -role intercluster`

Learn more about `network interface show` in the ONTAP command reference.

```
cluster01::> network interface show -service-policy default-intercluster
            Logical    Status     Network            Current
Current Is
Vserver     Interface  Admin/Oper Address/Mask       Node          Port
Home
----------- ---------- ---------- ------------------ -------------
------- ----
ipspace-IC1
            cluster01_icl01
                       up/up      192.168.1.201/24   cluster01-01  e0e
true
            cluster01_icl02
                       up/up      192.168.1.202/24   cluster01-02  e0f
true
```

10. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	`network interface show -service-policy default-intercluster -failover`
In ONTAP 9.5 and earlier:	`network interface show -role intercluster -failover`

Learn more about `network interface show` in the ONTAP command reference.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the SVM `e0e` port fail over to the`e0f`port:

```
cluster01::> network interface show -service-policy default-intercluster
-failover
         Logical         Home                  Failover        Failover
Vserver  Interface       Node:Port             Policy          Group
-------- --------------- --------------------- --------------- --------
ipspace-IC1
         cluster01_icl01 cluster01-01:e0e   local-only
intercluster01
                            Failover Targets:  cluster01-01:e0e,
                                               cluster01-01:e0f
         cluster01_icl02 cluster01-02:e0e   local-only
intercluster01
                            Failover Targets:  cluster01-02:e0e,
                                               cluster01-02:e0f
```

Configure peer relationships

Create ONTAP cluster peer relationships

Before you can protect your data by replicating it to a remote cluster for data backup and disaster recovery purposes, you should create a cluster peer relationship between the local and remote cluster.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to create set up snapshot replication. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

Several default protection policies are available. You must have created your protection policies if you want to use custom policies.

Before you begin

If you are using the ONTAP CLI, you must have created intercluster LIFs on every node in the clusters being peered using one of the following methods:

- Configure intercluster LIFs on shared data ports
- Configure intercluster LIFs on dedicated data ports
- Configure intercluster LIFs in custom IPspaces

Steps

Perform this task using ONTAP System Manager or the ONTAP CLI.

System Manager

1. In the local cluster, click **Cluster > Settings**.
2. In the **Intercluster Settings** section, click **Add Network Interfaces** and enter the IP address and subnet mask to add intercluster network interfaces for the cluster.

   Repeat this step on the remote cluster.

3. In the remote cluster, click **Cluster > Settings**.
4. Click ⋮ in the **Cluster Peers** section and select **Generate Passphrase**.
5. Select the remote ONTAP cluster version.
6. Copy the generated passphrase.
7. In the local cluster, under **Cluster peers**, click ⋮ and select **Peer cluster**.
8. In the **Peer cluster** window, paste the passphrase and click **Initiate cluster peering**.

CLI

1. On the destination cluster, create a peer relationship with the source cluster:

   ```
   cluster peer create -generate-passphrase -offer-expiration
   <MM/DD/YYYY HH:MM:SS|1...7days|1...168hours> -peer-addrs
   <peer_LIF_IPs> -initial-allowed-vserver-peers <svm_name|*> -ipspace
   <ipspace>
   ```

   If you specify both `-generate-passphrase` and `-peer-addrs`, only the cluster whose intercluster LIFs are specified in `-peer-addrs` can use the generated password.

   You can ignore the `-ipspace` option if you are not using a custom IPspace.
   Learn more about `cluster peer create` in the ONTAP command reference.

   If you are creating the peering relationship in ONTAP 9.6 or later and you do not want cross-cluster peering communications to be encrypted, you must use the `-encryption-protocol-proposed none` option to disable encryption.

   The following example creates a cluster peer relationship with an unspecified remote cluster, and pre-authorizes peer relationships with SVMs `vs1` and `vs2` on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -offer
-expiration 2days -initial-allowed-vserver-peers vs1,vs2

                     Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
                Expiration Time: 6/7/2017 08:16:10 EST
  Initial Allowed Vserver Peers: vs1,vs2
            Intercluster LIF IP: 192.140.112.101
              Peer Cluster Name: Clus_7ShR (temporary generated)

Warning: make a note of the passphrase - it cannot be displayed
again.
```

The following example creates a cluster peer relationship with the remote cluster at intercluster LIF IP addresses 192.140.112.103 and 192.140.112.104, and pre-authorizes a peer relationship with any SVM on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -peer-addrs
192.140.112.103,192.140.112.104 -offer-expiration 2days -initial
-allowed-vserver-peers *

                     Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
                Expiration Time: 6/7/2017 08:16:10 EST
  Initial Allowed Vserver Peers: vs1,vs2
            Intercluster LIF IP: 192.140.112.101,192.140.112.102
              Peer Cluster Name: Clus_7ShR (temporary generated)

Warning: make a note of the passphrase - it cannot be displayed
again.
```

The following example creates a cluster peer relationship with an unspecified remote cluster, and pre-authorizes peer relationships with SVMs`vs1` and `vs2` on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -offer
-expiration 2days -initial-allowed-vserver-peers vs1,vs2

                     Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
                Expiration Time: 6/7/2017 08:16:10 EST
  Initial Allowed Vserver Peers: vs1,vs2
            Intercluster LIF IP: 192.140.112.101
              Peer Cluster Name: Clus_7ShR (temporary generated)

Warning: make a note of the passphrase - it cannot be displayed
again.
```

2. On source cluster, authenticate the source cluster to the destination cluster:

```
cluster peer create -peer-addrs <peer_LIF_IPs> -ipspace <ipspace>
```

Learn more about `cluster peer create` in the ONTAP command reference.

The following example authenticates the local cluster to the remote cluster at intercluster LIF IP addresses 192.140.112.101 and 192.140.112.102:

```
cluster01::> cluster peer create -peer-addrs
192.140.112.101,192.140.112.102

Notice: Use a generated passphrase or choose a passphrase of 8 or
more characters.
        To ensure the authenticity of the peering relationship, use
a phrase or sequence of characters that would be hard to guess.

Enter the passphrase:
Confirm the passphrase:

Clusters cluster02 and cluster01 are peered.
```

Enter the passphrase for the peer relationship when prompted.

3. Verify that the cluster peer relationship was created:

```
cluster peer show -instance
```

```
cluster01::> cluster peer show -instance

                               Peer Cluster Name: cluster02
                   Remote Intercluster Addresses: 192.140.112.101,
192.140.112.102
              Availability of the Remote Cluster: Available
                             Remote Cluster Name: cluster2
                             Active IP Addresses: 192.140.112.101,
192.140.112.102
                           Cluster Serial Number: 1-80-123456
                  Address Family of Relationship: ipv4
            Authentication Status Administrative: no-authentication
               Authentication Status Operational: absent
                                Last Update Time: 02/05 21:05:41
                    IPspace for the Relationship: Default
```

4. Check the connectivity and status of the nodes in the peer relationship:

```
cluster peer health show
```

```
cluster01::> cluster peer health show
Node       cluster-Name                Node-Name
             Ping-Status               RDB-Health Cluster-Health
Avail…
---------- --------------------------- ---------  ---------------
--------

cluster01-02
           cluster02                   cluster02-01
             Data: interface_reachable
             ICMP: interface_reachable true       true
true
                                       cluster02-02
             Data: interface_reachable
             ICMP: interface_reachable true       true
true
```

Other ways to do this in ONTAP

To perform these tasks with…	See this content…
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery preparation overview

Create ONTAP intercluster SVM peer relationships

You can use the `vserver peer create` command to create a peer relationship between SVMs on local and remote clusters.

Before you begin

- The source and destination clusters must be peered.
- You must have "pre-authorized" peer relationships for the SVMs on the remote cluster.

For more information, see Creating a cluster peer relationship.

About this task

You can "pre-authorize" peer relationships for multiple SVMs by listing the SVMs in the `-initial-allowed-vserver` option when you create a cluster peer relationship. For more information, see Creating a cluster peer relationship.

Steps

1. On the data protection destination cluster, display the SVMs that are pre-authorized for peering:

   `vserver peer permission show`

   ```
   cluster02::> vserver peer permission show
   Peer Cluster         Vserver               Applications
   -------------------  --------------------  --------------------
   cluster02            vs1,vs2               snapmirror
   ```

2. On the data protection source cluster, create a peer relationship to a pre-authorized SVM on the data protection destination cluster:

   `vserver peer create -vserver *local_SVM* -peer-vserver *remote_SVM*`

   Learn more about `vserver peer create` in the ONTAP command reference.

   The following example creates a peer relationship between the local SVM `pvs1` and the pre-authorized remote SVM `vs1`:

   ```
   cluster01::> vserver peer create -vserver pvs1 -peer-vserver vs1
   ```

3. Verify the SVM peer relationship:

   `vserver peer show`

   ```
   cluster01::> vserver peer show
               Peer        Peer                           Peering
   Remote
   Vserver     Vserver     State        Peer Cluster      Applications
   Vserver
   ----------- ----------- ------------ ----------------- --------------
   ---------
   pvs1        vs1         peered       cluster02         snapmirror
   vs1
   ```

Add ONTAP intercluster SVM peer relationships

If you create an SVM after configuring a cluster peer relationship, you will need to add a peer relationship for the SVM manually. You can use the `vserver peer create` command to create a peer relationship between SVMs. After the peer relationship has been created, you can run `vserver peer accept` on the remote cluster to authorize the peer relationship.

Before you begin

The source and destination clusters must be peered.

About this task

You can create a peer relationships between SVMs in the same cluster for local data backup. Learn more about `vserver peer create` in the ONTAP command reference.

Administrators occasionally use the `vserver peer reject` command to reject a proposed SVM peer relationship. If the relationship between SVMs is in the `rejected` state, you must delete the relationship before you can create a new one. Learn more about `vserver peer reject` in the ONTAP command reference.

Steps

1. On the data protection source cluster, create a peer relationship with an SVM on the data protection destination cluster:

   `vserver peer create -vserver *local_SVM* -peer-vserver *remote_SVM* -applications snapmirror|file-copy|lun-copy -peer-cluster *remote_cluster*`

   The following example creates a peer relationship between the local SVM`pvs1` and the remote SVM`vs1`

   ```
   cluster01::> vserver peer create -vserver pvs1 -peer-vserver vs1
   -applications snapmirror -peer-cluster cluster02
   ```

   If the local and remote SVMs have the same names, you must use a *local name* to create the SVM peer relationship:

   ```
   cluster01::> vserver peer create -vserver vs1 -peer-vserver
   vs1 -applications snapmirror -peer-cluster cluster01
   -local-name cluster1vs1LocallyUniqueName
   ```

2. On the data protection source cluster, verify that the peer relationship has been initiated:

   `vserver peer show-all`

   Learn more about `vserver peer show-all` in the ONTAP command reference.

   The following example shows that the peer relationship between SVM`pvs1` and SVM`vs1` has been initiated:

```
cluster01::> vserver peer show-all
             Peer         Peer                        Peering
Vserver      Vserver      State       Peer Cluster    Applications
---------    ---------    ---------   -------------   ------------
pvs1         vs1          initiated    Cluster02        snapmirror
```

3. On the data protection destination cluster, display the pending SVM peer relationship:

   `vserver peer show`

   Learn more about `vserver peer show` in the ONTAP command reference.

   The following example lists the pending peer relationships for `cluster02`:

```
cluster02::> vserver peer show

                   Peer                Peer
Vserver            Vserver             State
-----------        -----------         ------------
vs1                pvs1                pending
```

4. On the data protection destination cluster, authorize the pending peer relationship:

   `vserver peer accept -vserver local_SVM -peer-vserver remote_SVM`

   Learn more about `vserver peer accept` in the ONTAP command reference.

   The following example authorizes the peer relationship between the local SVM `vs1` and the remote SVM `pvs1`:

```
cluster02::> vserver peer accept -vserver vs1 -peer-vserver pvs1
```

5. Verify the SVM peer relationship:

   `vserver peer show`

```
cluster01::> vserver peer show
            Peer        Peer                           Peering
Remote
Vserver     Vserver     State        Peer Cluster      Applications
Vserver
----------- ----------- ------------ ----------------- --------------
---------
pvs1        vs1         peered       cluster02         snapmirror
vs1
```

Enable ONTAP cluster peering encryption on peer relationships

Beginning with ONTAP 9.6, cluster peering encryption is enabled by default on all newly created cluster peering relationships. Cluster peering encryption uses a pre-shared key (PSK) and the Transport Security Layer (TLS) to secure cross-cluster peering communications. This adds an additional layer of security between the peered clusters.

About this task

If you are upgrading peered clusters to ONTAP 9.6 or later, and the peering relationship was created in ONTAP 9.5 or earlier, cluster peering encryption must be enabled manually after upgrading. Both clusters in the peering relationship must be running ONTAP 9.6 or later in order to enable cluster peering encryption.

Steps

1. On the destination cluster, enable encryption for communications with the source cluster:

   ```
   cluster peer modify source_cluster -auth-status-admin use-authentication
   -encryption-protocol-proposed tls-psk
   ```

2. When prompted enter a passphrase.
3. On the data protection source cluster, enable encryption for communication with the data protection destination cluster:

   ```
   cluster peer modify data_protection_destination_cluster -auth-status-admin
   use-authentication -encryption-protocol-proposed tls-psk
   ```

4. When prompted, enter the same passphrase entered on the destination cluster.

Learn more about `cluster peer modify` in the ONTAP command reference.

Remove ONTAP cluster peering encryption from peer relationships

By default, cluster peering encryption is enabled on all peer relationships created in ONTAP 9.6 or later. If you do not want to use encryption for cross-cluster peering communications, you can disable it.

Steps

1. On the destination cluster, modify communications with the source cluster to discontinue use of cluster

peering encryption:

  - To remove encryption, but maintain authentication enter:

    ```
    cluster peer modify <source_cluster> -auth-status-admin use-
    authentication -encryption-protocol-proposed none
    ```

  - To remove encryption and authentication:

    a. Modify the cluster peering policy to allow unauthenticated access:

    ```
    cluster peer policy modify -is-unauthenticated-access-permitted
    true
    ```

    b. Modify encryption and authentication access:

    ```
    cluster peer modify <source_cluster> -auth-status no-
    authentication
    ```

2. When prompted enter the passphrase.
3. Confirm the passphrase by re-entering it.
4. On the source cluster, disable encryption for communication with the destination cluster:

  - To remove encryption, but maintain authentication enter:

    ```
    cluster peer modify <destination_cluster> -auth-status-admin use-
    authentication -encryption-protocol-proposed none
    ```

  - To remove encryption and authentication:

    a. Modify the cluster peering policy to allow unauthenticated access:

    ```
    cluster peer policy modify -is-unauthenticated-access-permitted
    true
    ```

    b. Modify encryption and authentication access:

    ```
    cluster peer modify <destination_cluster> -auth-status no-
    authentication
    ```

5. When prompted, enter and re-enter the same passphrase you used on the destination cluster.

Manage local snapshots

Learn about managing local ONTAP snapshots

A *snapshot* is a read-only, point-in-time image of a volume. The image consumes minimal storage space and incurs negligible performance overhead because it records only changes to files since the last snapshot.

You can use a snapshot to restore the entire contents of a volume, or to recover individual files or LUNs. snapshots are stored in the directory `.snapshot` on the volume.

In ONTAP 9.4 and later, a FlexVol volume can contain up to 1023 snapshots.
In ONTAP 9.3 and earlier, a volume can contain up to 255 snapshots.

> Beginning with ONTAP 9.8, FlexGroup volumes can contain 1023 snapshots. For more information, see Protect FlexGroup volumes using snapshots.

Configure custom snapshot policies

Learn about configuring custom ONTAP snapshot policies

A *snapshot policy* defines how the system creates snapshots. The policy specifies when to create snapshots, how many copies to retain, and how to name them. For example, a system might create one snapshot every day at 12:10 a.m., retain the two most recent copies, and name the copies "daily.*`timestamp`*."

The default policy for a volume automatically creates snapshots on the following schedule, with the oldest snapshots deleted to make room for newer copies:

- A maximum of six hourly snapshots taken five minutes past the hour.
- A maximum of two daily snapshots taken Monday through Saturday at 10 minutes after midnight.
- A maximum of two weekly snapshots taken every Sunday at 15 minutes after midnight.

Unless you specify a snapshot policy when you create a volume, the volume inherits the snapshot policy associated with its containing storage virtual machine (SVM).

When to configure a custom ONTAP snapshot policy

If the default snapshot policy is not appropriate for a volume, you can configure a custom policy that modifies the frequency, retention, and name of snapshots. The schedule will be dictated mainly by the rate of change of the active file system.

You might back up a heavily used file system like a database every hour, while you back up rarely used files once a day. Even for a database, you will typically run a full backup once or twice a day, while backing up transaction logs every hour.

Other factors are the importance of the files to your organization, your Service Level Agreement (SLA), your Recovery Point Objective (RPO), and your Recovery Time Objective (RTO). Generally speaking, you should retain only as many snapshots as necessary.

Create an ONTAP snapshot job schedule

A snapshot policy requires at least one snapshot job schedule. You can use System Manager or the `job schedule cron create` command to create a job schedule. Learn more about `job schedule cron create` in the ONTAP command reference.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to create a snapshot job schedule. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

By default, ONTAP forms the names of snapshots by appending a timestamp to the job schedule name.

If you specify values for both day of the month and day of the week, the values are considered independently. For example, a cron schedule with the day specification `Friday` and the day of the month specification `13` runs every Friday and on the 13th day of each month, not just on every Friday the 13th.

Example 30. Steps

System Manager

1. Navigate to **Protection > Overview** and expand **Local policy settings**.
2. In the **Schedules** pane, click →.
3. In the **Schedules** window, click + Add.
4. In the **Add schedule** window, enter the schedule name, and choose the context and schedule type.
5. Click **Save**.

CLI

1. Create a job schedule:

```
job schedule cron create -name <job_name> -month <month> -dayofweek
<day_of_week> -day <day_of_month> -hour <hour> -minute <minute>
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name <job_name> -vserver <Vserver_name>
-month <month> -dayofweek <day_of_week> -day <day_of_month> -hour
<hour> -minute <minute>
```

The following example creates a job schedule named `myweekly` that runs on Saturdays at 3:00 a.m.:

```
cluster1::> job schedule cron create -name myweekly -dayofweek
"Saturday" -hour 3 -minute 0
```

The following example creates a schedule named `myweeklymulti` that specifies multiple days, hours and minutes:

```
job schedule cron create -name myweeklymulti -dayofweek
"Monday,Wednesday,Sunday" -hour 3,9,12 -minute 0,20,50
```

Create an ONTAP snapshot policy

A snapshot policy specifies when to create snapshots, how many copies to retain, and how to name them. For example, a system might create one snapshot every day at 12:10 a.m., retain the two most recent copies, and name them "daily.*`timestamp`*." A snapshot policy can contain up to five job schedules.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to create a snapshot policy. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

By default, ONTAP forms the names of snapshots by appending a timestamp to the job schedule name:

```
daily.2017-05-14_0013/              hourly.2017-05-15_1106/
daily.2017-05-15_0012/              hourly.2017-05-15_1206/
hourly.2017-05-15_1006/             hourly.2017-05-15_1306/
```

You can substitute a prefix for the job schedule name if you prefer.

The `snapmirror-label` option is for SnapMirror replication. For more information, see Defining a rule for a policy.

Steps

You can create a snapshot policy using System Manager or the ONTAP CLI. The procedure creates a snapshot policy on the local cluster only.

System Manager

1. Navigate to **Protection > Overview** and expand **Local policy settings**.
2. In the **Snapshot policies** pane, click →.
3. In the **Snapshot policies** tab, click + Add.
4. In the **Add snapshot policy** window, enter the policy name, and choose the scope.
5. Click + Add.
6. To select a schedule click the currently displayed schedule name, click ∨, and choose a different schedule.
7. Enter the maximum snapshots to retain, and, if needed, enter the SnapMirror label and the SnapLock retention period.
8. Click **Save**.

CLI

1. Create a snapshot policy:

```
volume snapshot policy create -vserver <SVM> -policy <policy_name>
-enabled true|false -schedule1 <schedule1_name> -count1
<copies_to_retain> -prefix1 <snapshot_prefix> -snapmirror-label1
<snapshot_label> ... -schedule5 <schedule5_name> -count5
<copies_to_retain> -prefix5 <snapshot_prefix> -snapmirror-label5
<snapshot_label>
```

The following example creates a snapshot policy named `snap_policy_daily` that runs on a `daily` schedule. The policy has a maximum of five snapshots, each with the name `daily.`*`timestamp`* and the SnapMirror label `daily`:

```
cluster1::> volume snapshot policy create -vserver vs0 -policy
snap_policy_daily -schedule1 daily -count1 5 -snapmirror-label1
daily
```

Manage snapshots manually

Create and delete snapshots manually

You can create snapshots manually when you can’t wait for a scheduled snapshot to be created, and you can delete snapshots when they are no longer needed.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to create an on-demand snapshot. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

Create a snapshot manually

You can manually create a snapshot using System Manager or the ONTAP CLI.

System Manager

Steps

1. Navigate to **Storage > Volumes** and select the **Snapshot copies** tab.
2. Click + Add.
3. In the **Add a snapshot** window, accept the default snapshot name or edit it if desired.
4. **Optional**: Add a SnapMirror label.
5. Click **Add**.

CLI

1. Create a snapshot:

```
volume snapshot create -vserver <SVM> -volume <volume> -snapshot
<snapshot_name>
```

Delete snapshots manually

You can manually delete a snapshot using System Manager or the ONTAP CLI.

System Manager

Steps

1. Navigate to **Storage > Volumes** and select the **Snapshot copies** tab.
2. Locate the snapshot you want to delete, click ⋮, and select **Delete**.
3. In the **Delete snapshot** window, select **Delete snapshot**.
4. Click **Delete**.

CLI

1. Use the `volume snapshot show` command to verify which snapshots you want to delete.

```
volume snapshot show -vserver <SVM> -volume <volume>
```

In this example, the command shows the snapshots on the volume vol3 in the SVM vs3.

```
cluster::> volume snapshot show -vserver vs3 -volume vol3

                                                   ---Blocks---
Vserver  Volume   Snapshot                Size     Total% Used%
-------- -------- ----------------------- -----    ------ -----
vs3      vol3
                  snap1.2013-05-01_0015   100KB     0%     38%
                  snap1.2013-05-08_0015   76KB     0%     32%
                  snap2.2013-05-09_0010   76KB     0%     32%
                  snap2.2013-05-10_0010   76KB     0%     32%
                  snap3.2013-05-10_1005   72KB     0%     31%
                  snap3.2013-05-10_1105   72KB     0%     31%
                  snap3.2013-05-10_1205   72KB     0%     31%
                  snap3.2013-05-10_1305   72KB     0%     31%
                  snap3.2013-05-10_1405   72KB     0%     31%
                  snap3.2013-05-10_1505   72KB     0%     31%
10 entries were displayed.
```

2. Delete a snapshot:

If you want to…	Enter this command…
Delete a single snapshot	`volume snapshot delete -vserver _svm_name_ -volume _vol_name_ -snapshot _snapshot_name_`

If you want to…	Enter this command…
Delete multiple snapshots	`volume snapshot delete -vserver _svm_name_ -volume _vol_name_ -snapshot _snapshot_name1_[,_snapshot_name2_,...]`
Delete all snapshots	`volume snapshot delete -vserver _svm_name_ -volume _vol_name_ -snapshot *`

Calculate reclaimable space before deleting snapshots

Beginning with ONTAP 9.10.1, you can use System Manager to select snapshots you want to delete and calculate the reclaimable space before you delete them.

Steps

1. Click **Storage > Volumes**.
2. Select the volume from which you want to delete snapshots.
3. Click **Snapshot Copies**.
4. Select one or more snapshots.
5. Click **Calculate Reclaimable Space**.

Manage the snapshot reserve

Learn about managing the ONTAP snapshot reserve

The *snapshot reserve* sets aside a percentage of disk space for snapshots, five percent by default. Because snapshots use space in the active file system when the snapshot reserve is exhausted, you might want to increase the snapshot reserve as needed. Alternatively, you can autodelete snapshots when the reserve is full.

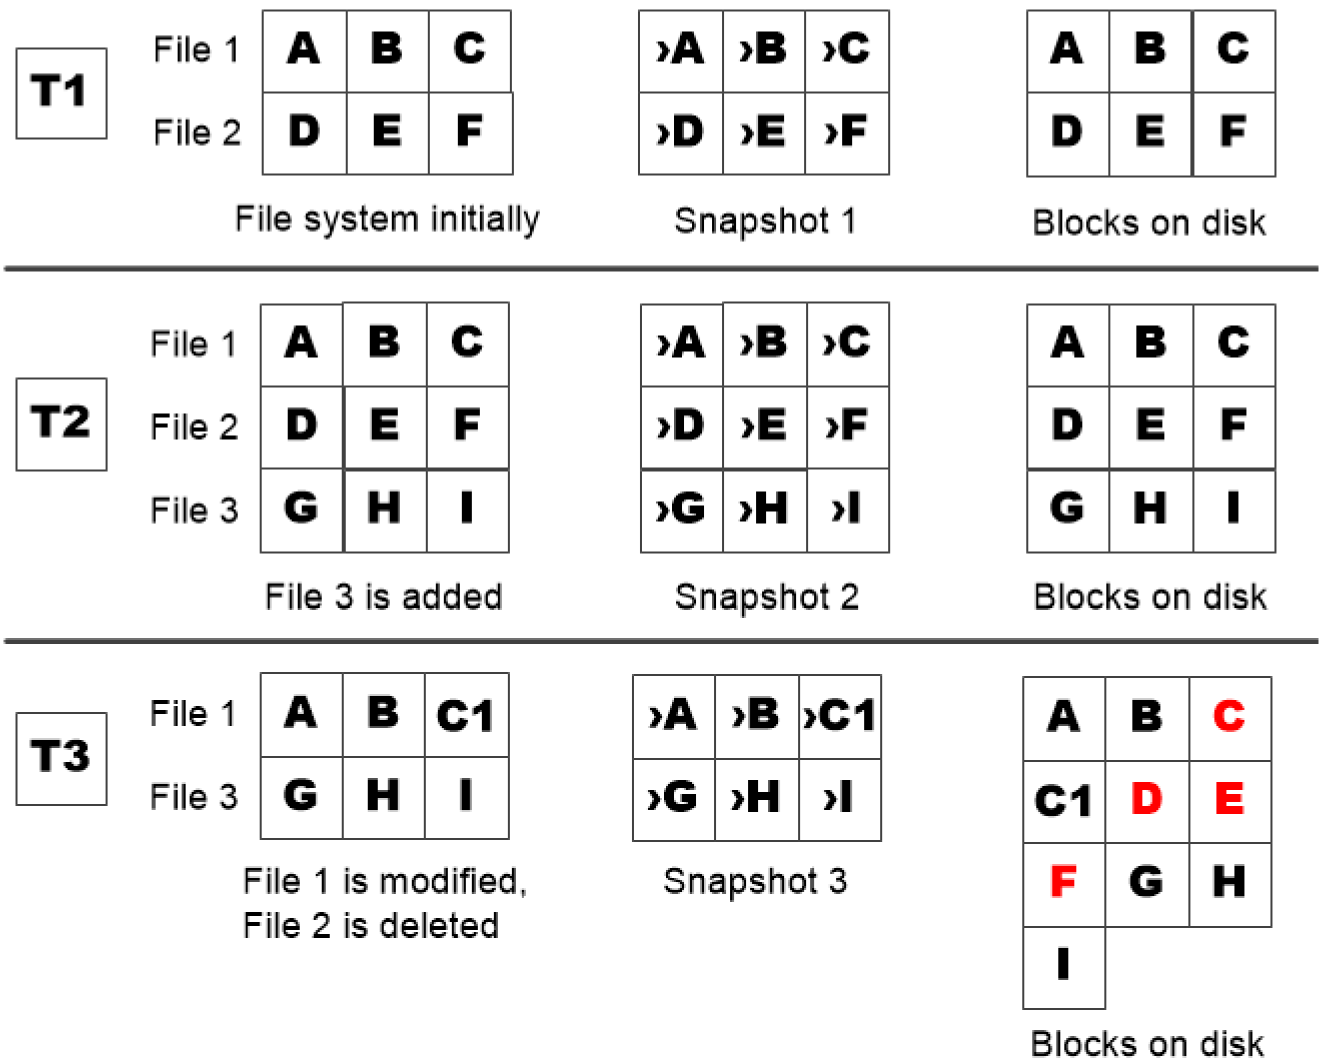
When to increase the snapshot reserve

In deciding whether to increase the snapshot reserve, it’s important to remember that a snapshot records only changes to files since the last snapshot was made. It consumes disk space only when blocks in the active file system are modified or deleted.

This means that the rate of change of the file system is the key factor in determining the amount of disk space used by snapshots. No matter how many snapshots you create, they will not consume disk space if the active file system has not changed.

A FlexVol volume containing database transaction logs, for example, might have a snapshot reserve as large as 20% to account for its greater rate of change. Not only will you want to create more snapshots to capture the more frequent updates to the database, you will also want to have a larger snapshot reserve to handle the additional disk space the snapshots consume.

A snapshot consists of pointers to blocks rather than copies of blocks. You can think of a pointer as a "claim" on a block: ONTAP "holds" the block until the snapshot is deleted.



A Snapshot copy consumes disk space only when blocks in the active file system are modified or deleted.

How deleting protected files can lead to less file space than expected

A snapshot points to a block even after you delete the file that used the block. This explains why an exhausted snapshot reserve might lead to the counter-intuitive result in which deleting an entire file system results in less space being available than the file system occupied.

Consider the following example. Before deleting any files, the `df` command output is as follows:

```
Filesystem          kbytes  used    avail   capacity
/vol/vol0/          3000000 3000000 0        100%
/vol/vol0/.snapshot 1000000 500000  500000    50%
```

After deleting the entire file system and making a snapshot of the volume, the `df` command generates the following output:

```
Filesystem          kbytes  used    avail   capacity
/vol/vol0/          3000000 2500000 500000    83%
/vol/vol0/.snapshot 1000000 3500000 0        350%
```

As the output shows, the entire 3 GB formerly used by the active file system is now being used by snapshots, in addition to the 0.5 GB used before the deletion.

Because the disk space used by the snapshots now exceeds the snapshot reserve, the overflow of 2.5 GB “spills” into the space reserved for active files, leaving you with 0.5 GB free space for files where you might reasonably have expected 3 GB.

Learn more about the commands described in this procedure in the ONTAP command reference.

Monitor ONTAP snapshot disk consumption

You can monitor snapshot disk consumption using the `df` command. The command displays the amount of free space in the active file system and the snapshot reserve.

Step

1. Display snapshot disk consumption: `df`

   The following example shows snapshot disk consumption:

   ```
   cluster1::> df
   Filesystem          kbytes  used    avail   capacity
   /vol/vol0/          3000000 3000000 0        100%
   /vol/vol0/.snapshot 1000000 500000  500000    50%
   ```

Learn more about the commands described in this procedure in the ONTAP command reference.

Check available ONTAP snapshot reserve on a volume

You might want to check how much snapshot reserve is available on a volume by using the `snapshot-reserve-available` parameter with the `volume show` command. Learn more about `volume show` in the ONTAP command reference.

Step

1. Check the snapshot reserve available on a volume:

```
vol show -vserver SVM -volume volume -fields snapshot-reserve-available
```

The following example displays the available snapshot reserve for `vol1`:

```
cluster1::> vol show -vserver vs0 -volume vol1 -fields snapshot-reserve-
available

vserver volume snapshot-reserve-available
------- ------ --------------------------
vs0     vol1   4.84GB
```

Modify the ONTAP snapshot reserve

You might want to configure a larger snapshot reserve to prevent snapshots from using space reserved for the active file system. You can decrease the snapshot reserve when you no longer need as much space for snapshots.

Step

1. Modify the snapshot reserve:

   ```
   volume modify -vserver SVM -volume volume -percent-snapshot-space snap_reserve
   ```

   Learn more about `volume modify` in the ONTAP command reference.

   The following example sets the snapshot reserve for `vol1` to 10 percent:

   ```
   cluster1::> volume modify -vserver vs0 -volume vol1 -percent-snapshot
   -space 10
   ```

Autodelete ONTAP snapshots

You can use the `volume snapshot autodelete modify` command to trigger automatic deletion of snapshots when the Snapshot reserve is exceeded. By default, the oldest snapshots are deleted first. Learn more about `volume snapshot autodelete modify` in the ONTAP command reference.

About this task

LUN and file clones are deleted when there are no more snapshots to be deleted.

Step

1. Autodelete snapshots:

   ```
   volume snapshot autodelete modify -vserver SVM -volume volume -enabled
   true|false -trigger volume|snap_reserve
   ```

   The following example autodeletes snapshots for `vol1` when the snapshot reserve is exhausted:

```
cluster1::> volume snapshot autodelete modify -vserver vs0 -volume vol1
-enabled true -trigger snap_reserve
```

Restore files from snapshots

Restore a file from an ONTAP snapshot on an NFS or SMB client

A user on an NFS or SMB client can restore a file directly from a snapshot without the intervention of a storage system administrator.

Every directory in the file system contains a subdirectory named `.snapshot` accessible to NFS and SMB users. The `.snapshot` subdirectory contains subdirectories corresponding to the snapshots of the volume:

```
$ ls .snapshot
daily.2017-05-14_0013/              hourly.2017-05-15_1106/
daily.2017-05-15_0012/              hourly.2017-05-15_1206/
hourly.2017-05-15_1006/             hourly.2017-05-15_1306/
```

Each subdirectory contains the files referenced by the snapshot. If users accidentally delete or overwrite a file, they can restore the file to the parent read-write directory by copying the file from the snapshot subdirectory to the read-write directory:

```
$ ls my.txt
ls: my.txt: No such file or directory
$ ls .snapshot
daily.2017-05-14_0013/              hourly.2017-05-15_1106/
daily.2017-05-15_0012/              hourly.2017-05-15_1206/
hourly.2017-05-15_1006/             hourly.2017-05-15_1306/
$ ls .snapshot/hourly.2017-05-15_1306/my.txt
my.txt
$ cp .snapshot/hourly.2017-05-15_1306/my.txt .
$ ls my.txt
my.txt
```

Enable and disable NFS and SMB client access to ONTAP snapshot directory

You can enable and disable access to the snapshot directory using the ONTAP CLI `-snapdir-access` option of the `volume modify` command, and beginning with ONTAP 9.10.1, you can use System Manager to enable or disable client systems to access to a snapshot directory on a volume. Enabling access makes the snapshot directory visible to clients and allows Windows clients to map a drive to the snapshot directory to view and access its contents. NFS and SMB clients can then restore a file or LUN from a snapshot.

You can enable or disable access to a volume’s snapshot directory by editing the volume settings or by editing the volume’s share settings.

Enable or disable client access to snapshot directory by editing a volume

Steps

You can enable and disable client snapshot directory access by using ONTAP System Manager or the ONTAP CLI. The snapshot directory on a volume is accessible to clients by default.

System Manager

1. Click **Storage > Volumes**.
2. Select the volume containing the snapshots directory you want to either show or hide.
3. Click ⋮ and select **Edit**.
4. In the **Snapshot Copies (Local) Settings** section, select or deselect **Show the Snapshot copies directory to clients**.
5. Click **Save**.

CLI

1. Check the snapshot directory access status:

```
volume show -vserver <SVM_name> -volume <vol_name> -fields snapdir-
access
```

Example:

```
clus1::> volume show -vserver vs0 -volume vol1 -fields snapdir-
access
vserver volume snapdir-access
------- ------ --------------
vs0     vol1   false
```

Learn more about `volume show` in the ONTAP command reference.

2. Enable or disable the snapshot directory access:

```
volume modify -vserver <SVM_name> -volume <vol_name> -snapdir-access
<true|false>
```

The following example enables snapshot directory access on vol1:

```
clus1::> volume modify -vserver vs0 -volume vol1 -snapdir-access
true
Volume modify successful on volume vol1 of Vserver vs0.
```

Learn more about `volume modify` in the ONTAP command reference.

Enable or disable client access to snapshot directory by editing a share

The snapshot directory on a volume is accessible to clients by default.

Steps

1. Click **Storage > Shares**.
2. Select the volume containing the snapshots directory you want to either show or hide.
3. Click ⋮ and select **Edit**.
4. In the **Share Properties** section, select or deselect **Allow clients to access snapshots directory**.
5. Click **Save**.

Restore a single file from an ONTAP snapshot

You can use the `volume snapshot restore-file` command to restore a single file or LUN from a snapshot. You can restore the file to a different location in the parent read-write volume if you do not want to replace an existing file.

About this task

If you are restoring an existing LUN, a LUN clone is created and backed up in the form of a snapshot. During the restore operation, you can read from and write to the LUN.

Files with streams are restored by default.

Steps

1. List the snapshots in a volume:

   `volume snapshot show -vserver *SVM* -volume *volume*`

   Learn more about `volume snapshot show` in the ONTAP command reference.

   The following example shows the snapshots in `vol1`:

   ```
   clus1::> volume snapshot show -vserver vs1 -volume vol1

   Vserver Volume Snapshot                State    Size  Total% Used%
   ------- ------ ---------- ----------- ------   -----  ------ -----
   vs1     vol1   hourly.2013-01-25_0005  valid   224KB     0%    0%
                  daily.2013-01-25_0010   valid   92KB      0%    0%
                  hourly.2013-01-25_0105  valid   228KB     0%    0%
                  hourly.2013-01-25_0205  valid   236KB     0%    0%
                  hourly.2013-01-25_0305  valid   244KB     0%    0%
                  hourly.2013-01-25_0405  valid   244KB     0%    0%
                  hourly.2013-01-25_0505  valid   244KB     0%    0%

   7 entries were displayed.
   ```

2. Restore a file from a snapshot:

   `volume snapshot restore-file -vserver *SVM* -volume *volume* -snapshot *snapshot* -path *file_path* -restore-path *destination_path*`

Learn more about `volume snapshot restore-file` in the ONTAP command reference.

The following example restores the file `myfile.txt`:

```
cluster1::> volume snapshot restore-file -vserver vs0 -volume vol1
-snapshot daily.2013-01-25_0010 -path /myfile.txt
```

Restore part of a file from an ONTAP snapshot

You can use the `volume snapshot partial-restore-file` command to restore a range of data from a snapshot to a LUN or to an NFS or SMB container file, assuming you know the starting byte offset of the data and the byte count. You might use this command to restore one of the databases on a host that stores multiple databases in the same LUN.

Beginning with ONTAP 9.12.1, partial restore is available for volumes using SnapMirror active sync.

Steps

1. List the snapshots in a volume:

   `volume snapshot show -vserver` *`SVM`* `-volume` *`volume`*

   Learn more about `volume snapshot show` in the ONTAP command reference.

   The following example shows the snapshots in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1

Vserver Volume Snapshot                State    Size  Total% Used%
------- ------ ---------- ----------- ------   -----  ------ -----
vs1     vol1   hourly.2013-01-25_0005  valid   224KB     0%    0%
               daily.2013-01-25_0010   valid   92KB      0%    0%
               hourly.2013-01-25_0105  valid   228KB     0%    0%
               hourly.2013-01-25_0205  valid   236KB     0%    0%
               hourly.2013-01-25_0305  valid   244KB     0%    0%
               hourly.2013-01-25_0405  valid   244KB     0%    0%
               hourly.2013-01-25_0505  valid   244KB     0%    0%

7 entries were displayed.
```

2. Restore part of a file from a snapshot:

   `volume snapshot partial-restore-file -vserver` *`SVM`* `-volume` *`volume`* `-snapshot` *`snapshot`* `-path` *`file_path`* `-start-byte` *`starting_byte`* `-byte-count` *`byte_count`*

   The starting byte offset and byte count must be multiples of 4,096.

The following example restores the first 4,096 bytes of the file `myfile.txt`:

```
cluster1::> volume snapshot partial-restore-file -vserver vs0 -volume
vol1 -snapshot daily.2013-01-25_0010 -path /myfile.txt -start-byte 0
-byte-count 4096
```

Restore the contents of a volume from an ONTAP snapshot

You can recover a volume to an earlier point in time by restoring from a snapshot. You can use System Manager or the `volume snapshot restore` command to restore the contents of a volume from a snapshot. Learn more about `volume snapshot restore` in the ONTAP command reference.

About this task

If the volume has SnapMirror relationships, manually replicate all mirror copies of the volume immediately after you restore from a snapshot. Not doing so can result in unusable mirror copies that must be deleted and recreated.

Steps

You can use System Manager or the ONTAP CLI to restore from an earlier snapshot.

System Manager

1. Click **Storage** and select a volume.
2. Under **Snapshot copies**, click ⋮ next to the snapshot you want to restore, and select **Restore**.

CLI

1. List the snapshots in a volume:

```
volume snapshot show -vserver <SVM> -volume <volume>
```

The following example shows the snapshot in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1

Vserver Volume Snapshot                State    Size  Total% Used%
------- ------ ---------- ----------- ------   -----  ------ -----
vs1     vol1   hourly.2013-01-25_0005  valid   224KB     0%    0%
               daily.2013-01-25_0010   valid   92KB      0%    0%
               hourly.2013-01-25_0105  valid   228KB     0%    0%
               hourly.2013-01-25_0205  valid   236KB     0%    0%
               hourly.2013-01-25_0305  valid   244KB     0%    0%
               hourly.2013-01-25_0405  valid   244KB     0%    0%
               hourly.2013-01-25_0505  valid   244KB     0%    0%

7 entries were displayed.
```

2. Restore the contents of a volume from a snapshot:

```
volume snapshot restore -vserver <SVM> -volume <volume> -snapshot
<snapshot>
```

The following example restores the contents of `vol1`:

```
cluster1::> volume snapshot restore -vserver vs0 -volume vol1
-snapshot daily.2013-01-25_0010
```

SnapMirror volume replication

Learn about SnapMirror volume replication

Learn about ONTAP SnapMirror asynchronous disaster recovery

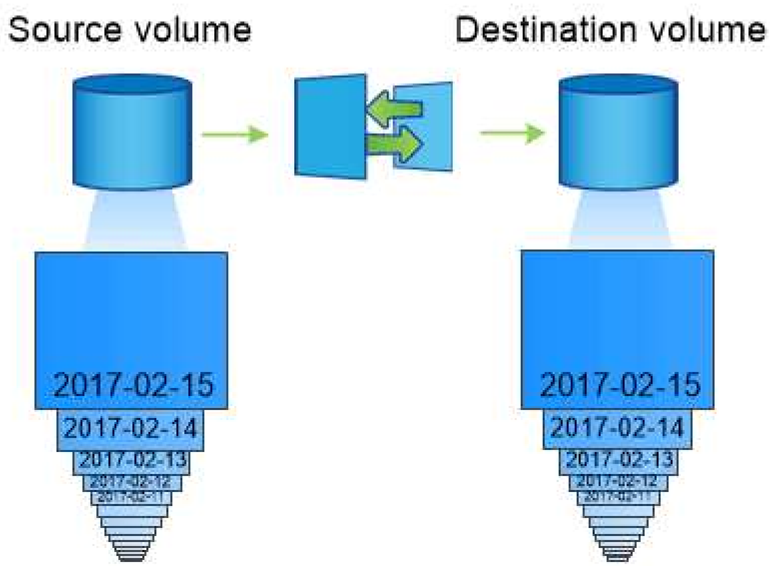
SnapMirror is disaster recovery technology, designed for failover from primary storage to secondary storage at a geographically remote site. As its name implies, SnapMirror creates a replica, or *mirror,* of your working data in secondary storage from which you can continue to serve data in the event of a catastrophe at the primary site.

If the primary site is still available to serve data, you can simply transfer any needed data back to it, and not serve clients from the mirror at all. As the failover use case implies, the controllers on the secondary system should be equivalent or nearly equivalent to the controllers on the primary system to serve data efficiently from mirrored storage.

Data protection relationships

Data is mirrored at the volume level. The relationship between the source volume in primary storage and the destination volume in secondary storage is called a *data protection relationship.* The clusters in which the volumes reside and the SVMs that serve data from the volumes must be peered. A peer relationship enables clusters and SVMs to exchange data securely.

This figure illustrates SnapMirror data protection relationships:



A SnapMirror data protection relationship typically mirrors the Snapshot copies available on the source volume.

Scope of data protection relationships

You can create a data protection relationship directly between volumes or between the SVMs that own the volumes. In an *SVM data protection relationship,* all or part of the SVM configuration, from NFS exports and SMB shares to RBAC, is replicated, as well as the data in the volumes that the SVM owns.

You can also use SnapMirror for special data protection applications:

- A *load-sharing mirror* copy of the SVM root volume ensures that data remains accessible in the event of a node outage or failover.
- A data protection relationship between *SnapLock volumes* lets you replicate WORM files to secondary

storage.

Archive and compliance using SnapLock technology

- Beginning with ONTAP 9.13.1, you can use SnapMirror asynchronous to protect consistency groups. Beginning with ONTAP 9.14.1, you can use SnapMirror asynchronous to replicate volume-granular snapshots to the destination cluster using the consistency group relationship. For more information, see Configure SnapMirror asynchronous protection.

How SnapMirror data protection relationships are initialized

The first time you invoke SnapMirror, it performs a *baseline transfer* from the source volume to the destination volume. The *SnapMirror policy* for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default SnapMirror policy `MirrorAllSnapshots` involves the following steps:

- Make a snapshot of the source volume.
- Transfer the snapshot and all the data blocks it references to the destination volume.
- Transfer the remaining, less recent snapshots on the source volume to the destination volume for use in case the “active” mirror is corrupted.

How SnapMirror data protection relationships are updated

Updates are asynchronous, following the schedule you configure. Retention mirrors the snapshot policy on the source.

At each update under the `MirrorAllSnapshots` policy, SnapMirror creates a snapshot of the source volume and transfers that snapshot and any snapshots that have been made since the last update. In the following output from the `snapmirror policy show` command for the `MirrorAllSnapshots` policy, note the following:

- `Create Snapshot` is “true”, indicating that `MirrorAllSnapshots` creates a snapshot when SnapMirror updates the relationship.
- `MirrorAllSnapshots` has rules “sm_created” and “all_source_snapshots”, indicating that both the snapshot created by SnapMirror and any snapshots that have been made since the last update are transferred when SnapMirror updates the relationship.

```
cluster_dst::> snapmirror policy show -policy MirrorAllSnapshots -instance

                     Vserver: vs0
       SnapMirror Policy Name: MirrorAllSnapshots
       SnapMirror Policy Type: async-mirror
                 Policy Owner: cluster-admin
                  Tries Limit: 8
            Transfer Priority: normal
    Ignore accesstime Enabled: false
      Transfer Restartability: always
  Network Compression Enabled: false
              Create Snapshot: true
                      Comment: SnapMirror asynchronous policy for mirroring
all snapshots
                               and the latest active file system.
        Total Number of Rules: 2
                   Total Keep: 2
                        Rules: SnapMirror Label     Keep  Preserve Warn
Schedule Prefix
                               ----------------     ----  -------- ----
-------- ------
                               sm_created              1  false       0 -
-
                               all_source_snapshots    1  false       0 -
-
```

MirrorLatest policy

The preconfigured `MirrorLatest` policy works exactly the same way as `MirrorAllSnapshots`, except that only the snapshot created by SnapMirror is transferred at initialization and update.

```
                        Rules: SnapMirror Label     Keep  Preserve Warn
Schedule Prefix
                               ----------------     ----  -------- ----
-------- ------
                               sm_created              1  false       0 -
-
```

Learn about ONTAP SnapMirror synchronous disaster recovery

Beginning with ONTAP 9.5, SnapMirror synchronous (SM-S) technology is supported on all FAS and AFF platforms that have at least 16 GB of memory and on all ONTAP Select platforms. SnapMirror synchronous technology is a per-node, licensed feature that provides synchronous data replication at the volume level.

This functionality addresses the regulatory and national mandates for synchronous replication in financial, healthcare, and other regulated industries where zero data loss is required.

SnapMirror synchronous operations allowed

The limit on the number of SnapMirror synchronous replication operations per HA pair depends on the controller model.

The following table lists the number of SnapMirror synchronous operations that are allowed per HA pair according to platform type and ONTAP release.

Platform	Releases earlier than ONTAP 9.9.1	ONTAP 9.9.1	ONTAP 9.10.1	ONTAP 9.11.1 through ONTAP 9.14.1
AFF	80	160	200	400
ASA	80	160	200	400
FAS	40	80	80	80
ONTAP Select	20	40	40	40

Supported features

The following table indicates the features supported with SnapMirror synchronous and the ONTAP releases in which support is available.

Feature	Release first supported	Additional information
Antivirus on the primary volume of the SnapMirror synchronous relationship	ONTAP 9.6	
Application-created snapshot replication	ONTAP 9.7	If a snapshot is tagged with the appropriate label at the time of the `snapshot create` operation, using the CLI or the ONTAP API, SnapMirror synchronous replicates the snapshots, both user created or those created with external scripts, after quiescing the applications. Scheduled snapshots created using a snapshot policy are not replicated. For more information about replicating application-created snapshots, see the Knowledge Base article: How to replicate application created snapshots with SnapMirror synchronous.
Clone auto delete	ONTAP 9.6	

FabricPool aggregates with tiering policy of None, Snapshot, or Auto are supported with SnapMirror synchronous source and destination.	ONTAP 9.5	The destination volume in a FabricPool aggregate cannot be set to All tiering policy.
FC	ONTAP 9.5	Over all networks for which latency does not exceed 10ms
FC-NVMe	ONTAP 9.7	
File clones	ONTAP 9.7	
FPolicy on the primary volume of the SnapMirror synchronous relationship	ONTAP 9.6	
Hard and soft quotas on the primary volume of the SnapMirror synchronous relationship	ONTAP 9.6	The quota rules are not replicated to the destination; therefore, the quota database is not replicated to the destination.
Intra-cluster synchronous relationships	ONTAP 9.14.1	High availability is provided when source and destination volumes are placed on different HA pairs. If the entire cluster goes down, access to volumes will not be possible until the cluster is recovered. Intra-cluster SnapMirror synchronous relationships will contribute to the overall limit of simultaneous relationships per HA pair.
iSCSI	ONTAP 9.5	
LUN clones and NVMe namespace clones	ONTAP 9.7	
LUN clones backed by application-created snapshots	ONTAP 9.7	
Mixed protocol access (NFS v3 and SMB)	ONTAP 9.6	
NDMP/NDMP restore	ONTAP 9.13.1	Both the source and destination cluster must be running ONTAP 9.13.1 or later to use NDMP with SnapMirror Synchronous. For more information, see Transfer data using ndmp copy.
Non-disruptive SnapMirror synchronous operations (NDO) on AFF/ASA platforms, only.	ONTAP 9.12.1	Support for non-disruptive operations enables you to perform many common maintenance tasks without scheduling down time. Operations supported include takeover and giveback, and volume move, provided that a single node is surviving among each of the two clusters.
NFS v4.2	ONTAP 9.10.1	
NFS v4.0	ONTAP 9.6	
NFS v4.1	ONTAP 9.6	
NVMe/TCP	9.10.1	
Removal of high metadata operation frequency limitation	ONTAP 9.6	

Security for sensitive data in-transit using TLS 1.2 encryption	ONTAP 9.6	
Single file and partial file restore	ONTAP 9.13.1	
SMB 2.0 or later	ONTAP 9.6	
SnapMirror synchronous mirror-mirror cascade	ONTAP 9.6	The relationship from the destination volume of the SnapMirror synchronous relationship must be an SnapMirror asynchronous relationship.
SVM disaster recovery	ONTAP 9.6	* A SnapMirror synchronous source can also be a SVM disaster recovery source, for example, a fan-out configuration with SnapMirror synchronous as one leg and SVM disaster recovery as the other. * A SnapMirror synchronous source cannot be an SVM disaster recovery destination because SnapMirror synchronous does not support cascading a data protection source. You must release the synchronous relationship before performing an SVM disaster recovery flip resync in the destination cluster. * A SnapMirror synchronous destination cannot be an SVM disaster recovery source because SVM disaster recovery does not support replication of DP volumes. A flip resync of the synchronous source would result in the SVM disaster recovery excluding the DP volume in the destination cluster.
Tape-based restore to the source volume	ONTAP 9.13.1	
Timestamp parity between source and destination volumes for NAS	ONTAP 9.6	If you have upgraded from ONTAP 9.5 to ONTAP 9.6, the timestamp is replicated only for any new and modified files in the source volume. The timestamp of existing files in the source volume is not synchronized.

Unsupported features

The following features are not supported with SnapMirror synchronous relationships:

- Consistency groups
- DP_Optimized (DPO) systems
- FlexGroup volumes
- FlexCache volumes
- Global throttling
- In a fan-out configuration, only one relationship can be a SnapMirror synchronous relationship; all the other relationships from the source volume must be SnapMirror asynchronous relationships.
- LUN move
- MetroCluster configurations

* Mixed SAN and NVMe access
  LUNs and NVMe namespaces are not supported on the same volume or SVM.
* SnapCenter
* SnapLock volumes
* Tamperproof snapshots
* Tape backup or restore using dump and SMTape on the destination volume
* Throughput floor (QoS Min) for source volumes
* Volume SnapRestore
* VVol

Modes of operation

SnapMirror synchronous has two modes of operation based on the type of the SnapMirror policy used:

* **Sync mode**
  In Sync mode, application I/O operations are sent in parallel to the primary and secondary storage systems. If the write to the secondary storage is not completed for any reason, the application is allowed to continue writing to the primary storage. When the error condition is corrected, SnapMirror synchronous technology automatically resynchronizes with the secondary storage and resumes replicating from primary storage to secondary storage in synchronous mode.
  In Sync mode, RPO=0 and RTO is very low until a secondary replication failure occurs at which time RPO and RTO become indeterminate, but equal the time to repair the issue that caused secondary replication to fail and for the resync to complete.
* **StrictSync mode**
  SnapMirror synchronous can optionally operate in StrictSync mode. If the write to the secondary storage is not completed for any reason, the application I/O fails, thereby ensuring that the primary and secondary storage are identical. Application I/O to the primary resumes only after the SnapMirror relationship returns to the `InSync` status. If the primary storage fails, application I/O can be resumed on the secondary storage, after failover, with no loss of data.
  In StrictSync mode RPO is always zero, and RTO is very low.

Relationship status

The status of a SnapMirror synchronous relationship is always in the `InSync` status during normal operation. If the SnapMirror transfer fails for any reason, the destination is not in sync with the source and can go to the `OutofSync` status.

For SnapMirror synchronous relationships, the system automatically checks the relationship status (`InSync` or `OutofSync`) at a fixed interval. If the relationship status is `OutofSync`, ONTAP automatically triggers the auto resync process to bring back the relationship to the `InSync` status. Auto resync is triggered only if the transfer fails due to any operation, such as unplanned storage failover at source or destination or a network outage. User-initiated operations such as `snapmirror quiesce` and `snapmirror break` do not trigger auto resync.

If the relationship status becomes `OutofSync` for a SnapMirror synchronous relationship in the StrictSync mode, all I/O operations to the primary volume are stopped. The `OutofSync` state for SnapMirror synchronous relationship in the Sync mode is not disruptive to the primary and I/O operations are allowed on the primary volume.

Default ONTAP data protection policies

ONTAP includes several default protection policies you can use for your data protection relationships. The policy you use depends on the protection relationship type.

If the default policies don't meet your data protection relationships needs, you can create a custom policy.

List of default protection policies and descriptions

Default protection policies and their associated policy types are described below.

Name	Description	Policy type
Asynchronous	A unified SnapMirror asynchronous and vault policy for mirroring the latest active file system and daily and weekly snapshots with an hourly transfer schedule.	Asynchronous
AutomatedFailOver	Policy for SnapMirror synchronous with zero RTO guarantee where client I/O will not be disrupted on replication failure.	Synchronous
AutomatedFailOverDuplex	Policy for SnapMirror synchronous with zero RTO guarantee and bi-directional sync replication.	Synchronous
CloudBackupDefault	Vault policy with daily rule.	Asynchronous
Continuous	Policy for S3 bucket mirroring.	Continuous
DailyBackup	Vault policy with a daily rule and a daily transfer schedule.	Asynchronous
DPDefault	SnapMirror asynchronous policy for mirroring all snapshots and the latest active file system.	Asynchronous
MirrorAllSnapshots	SnapMirror asynchronous policy for mirroring all snapshots and the latest active file system.	Asynchronous
MirrorAllSnapshotsDiscardNetwork	SnapMirror asynchronous policy for mirroring all snapshots and the latest active file system excluding the network configurations.	Asynchronous
MirrorAndVault	A unified SnapMirror asynchronous and vault policy for mirroring the latest active file system and daily and weekly snapshots.	Asynchronous
MirrorAndVaultDiscardNetwork	A unified SnapMirror asynchronous and vault policy for mirroring the latest active file system and daily and weekly snapshots excluding the network configurations.	Asynchronous
MirrorLatest	SnapMirror asynchronous policy for mirroring the latest active file system.	Asynchronous

Name	Description	Policy type
SnapCenterSync	Policy for SnapMirror synchronous for SnapCenter with Application Created Snapshot configuration.	Synchronous
StrictSync	Policy for SnapMirror synchronous where client access will be disrupted on replication failure.	Synchronous
Synchronous	Policy for SnapMirror synchronous where client access will not be disrupted on replication failure.	Synchronous
Unified7year	Unified SnapMirror policy with 7-year retention.	Asynchronous
XDPDefault	Vault policy with daily and weekly rules.	Asynchronous

Learn about workloads supported by ONTAP StrictSync and Sync policies

StrictSync and Sync policies support all LUN-based applications with FC, iSCSI, and FC-NVMe protocols, as well as NFSv3 and NFSv4 protocols for enterprise applications such as databases, VMWare, quota, SMB, and so on. Beginning with ONTAP 9.6, SnapMirror synchronous can be used for enterprise file services such as electronic design automation (EDA), home directories, and software build workloads.

In ONTAP 9.5, for a Sync policy, you need to consider a few important aspects while selecting the NFSv3 or NFSv4 workloads. The amount of data read or write operations by workloads is not a consideration, as Sync policy can handle high read or write IO workloads. In ONTAP 9.5, workloads that have excessive file creation, directory creation, file permission changes, or directory permission changes may not be suitable (these are referred to as high-metadata workloads). A typical example of a high-metadata workload is a DevOps workload in which you create multiple test files, run automation, and delete the files. Another example is parallel build workload that generate multiple temporary files during compilation. The impact of a high rate of write metadata activity is that it can cause synchronization between mirrors to temporarily break which stalls the read and write IOs from the client.

Beginning with ONTAP 9.6, these limitations are removed and SnapMirror synchronous can be used for enterprise file services workloads that include multiuser environments, such as home directories and software build workloads.

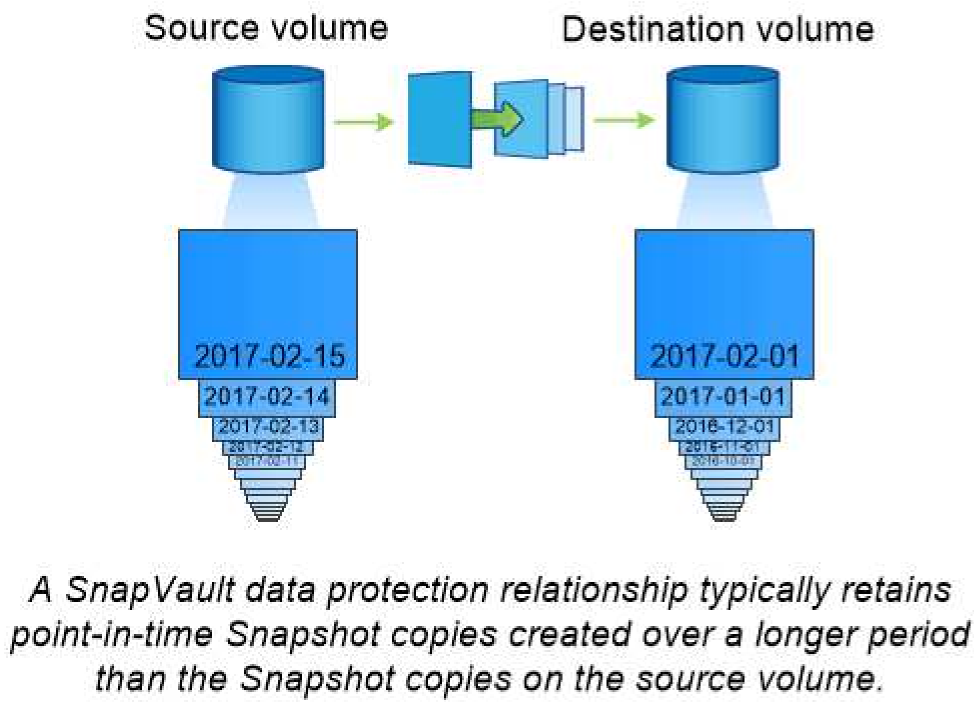
Learn about vault archiving using ONTAP SnapMirror technology

SnapMirror vault policies replace SnapVault technology in ONTAP 9.3 and later. You use a SnapMirror vault policy for disk-to-disk snapshot replication for standards compliance and other governance-related purposes. In contrast to a SnapMirror relationship, in which the destination usually contains only the snapshots currently in the source volume, a vault destination typically retains point-in-time snapshots created over a much longer period.

You might want to keep monthly snapshots of your data over a 20-year span, for example, to comply with government accounting regulations for your business. Since there is no requirement to serve data from vault storage, you can use slower, less expensive disks on the destination system.

The figure below illustrates SnapMirror vault data protection relationships.



How vault data protection relationships are initialized

The SnapMirror policy for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default vault policy `XDPDefault` makes a snapshot of the source volume, then transfers that copy and the data blocks it references to the destination volume. Unlike SnapMirror relationships, a vault backup does not include older snapshots in the baseline.

How vault data protection relationships are updated

Updates are asynchronous, following the schedule you configure. The rules you define in the policy for the relationship identify which new snapshots to include in updates and how many copies to retain. The labels defined in the policy ("monthly," for example) must match one or more labels defined in the snapshot policy on the source. Otherwise, replication fails.

At each update under the `XDPDefault` policy, SnapMirror transfers snapshots that have been made since the last update, provided they have labels matching the labels defined in the policy rules. In the following output from the `snapmirror policy show` command for the `XDPDefault` policy, note the following:

- `Create Snapshot` is "false", indicating that `XDPDefault` does not create a snapshot when SnapMirror updates the relationship.
- `XDPDefault` has rules "daily" and "weekly", indicating that all snapshots with matching labels on the source are transferred when SnapMirror updates the relationship.

```
cluster_dst::> snapmirror policy show -policy XDPDefault -instance

                     Vserver: vs0
      SnapMirror Policy Name: XDPDefault
      SnapMirror Policy Type: vault
                Policy Owner: cluster-admin
                 Tries Limit: 8
           Transfer Priority: normal
   Ignore accesstime Enabled: false
     Transfer Restartability: always
 Network Compression Enabled: false
             Create Snapshot: false
                     Comment: Default policy for XDP relationships with
daily and weekly
                              rules.
       Total Number of Rules: 2
                  Total Keep: 59
                       Rules: SnapMirror Label     Keep  Preserve Warn
Schedule Prefix
                              ----------------     ----  -------- ----
-------- ------
                              daily                   7  false       0 -
-
                              weekly                 52  false       0 -

Learn about ONTAP SnapMirror unified replication

SnapMirror *unified replication* allows you to configure disaster recovery and archiving on the same destination volume. When unified replication is appropriate, it offers benefits in reducing the amount of secondary storage you need, limiting the number of baseline transfers, and decreasing network traffic.

How unified data protection relationships are initialized

As with SnapMirror, unified data protection performs a baseline transfer the first time you invoke it. The SnapMirror policy for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default unified data protection policy `MirrorAndVault` makes a snapshot of the source volume, then transfers that copy and the data blocks it references to the destination volume. Like vault archiving, unified data protection does not include older snapshots in the baseline.

How unified data protection relationships are updated

At each update under the `MirrorAndVault` policy, SnapMirror creates a snapshot of the source volume and transfers that snapshot and any snapshots that have been made since the last update, provided they have labels matching the labels defined in the snapshot policy rules. In the following output from the `snapmirror policy show` command for the `MirrorAndVault` policy, note the following:

- `Create Snapshot` is “true”, indicating that `MirrorAndVault` creates a snapshot when SnapMirror updates the relationship.
- `MirrorAndVault` has rules “sm_created”, “daily”, and “weekly”, indicating that both the snapshot created by SnapMirror and the snapshots with matching labels on the source are transferred when SnapMirror updates the relationship.

```
cluster_dst::> snapmirror policy show -policy MirrorAndVault -instance

                     Vserver: vs0
      SnapMirror Policy Name: MirrorAndVault
      SnapMirror Policy Type: mirror-vault
                Policy Owner: cluster-admin
                 Tries Limit: 8
           Transfer Priority: normal
   Ignore accesstime Enabled: false
     Transfer Restartability: always
 Network Compression Enabled: false
             Create Snapshot: true
                     Comment: A unified SnapMirror synchronous and
SnapVault policy for
                              mirroring the latest file system and daily
and weekly snapshots.
       Total Number of Rules: 3
                  Total Keep: 59
                       Rules: SnapMirror Label     Keep  Preserve Warn
Schedule Prefix
                              ----------------     ----  -------- ----
-------- ------
                              sm_created              1  false       0 -
-
                              daily                   7  false       0 -
-
                              weekly                 52  false       0 -
-
```

Unified7year policy

The preconfigured `Unified7year` policy works exactly the same way as `MirrorAndVault`, except that a fourth rule transfers monthly snapshots and retains them for seven years.

```
                     Rules: SnapMirror Label     Keep  Preserve Warn
Schedule Prefix
                            ----------------     ----  -------- ----
-------- ------
                            sm_created              1  false       0 -
-
                            daily                   7  false       0 -
-
                            weekly                 52  false       0 -
-
                            monthly                84  false       0 -
-
```

Protect against possible data corruption

Unified replication limits the contents of the baseline transfer to the snapshot created by SnapMirror at initialization. At each update, SnapMirror creates another snapshot of the source and transfers that snapshot and any new snapshots that have labels matching the labels defined in the snapshot policy rules.

You can protect against the possibility that an updated snapshot is corrupted by creating a copy of the last transferred snapshot on the destination. This “local copy” is retained regardless of the retention rules on the source, so that even if the snapshot originally transferred by SnapMirror is no longer available on the source, a copy of it will be available on the destination.

When to use unified data replication

You need to weigh the benefit of maintaining a full mirror against the advantages that unified replication offers in reducing the amount of secondary storage, limiting the number of baseline transfers, and decreasing network traffic.

The key factor in determining the appropriateness of unified replication is the rate of change of the active file system. A traditional mirror might be better suited to a volume holding hourly snapshots of database transaction logs, for example.

When an ONTAP data protection destination volume grows automatically

During a data protection mirror transfer, the destination volume grows automatically in size if the source volume has grown, provided there is available space in the aggregate that contains the volume.

This behavior occurs irrespective of any automatic growth setting on the destination. You cannot limit the volume’s growth or prevent ONTAP from growing it.

By default, data protection volumes are set to the `grow_shrink` autosize mode, which enables the volume to grow or shrink in response to the amount of used space. The max-autosize for data protection volumes is equal to the maximum FlexVol size and is platform dependent. For example:

- FAS8200, default DP volume max-autosize = 100TB

For more information, see NetApp Hardware Universe.

Learn about ONTAP data protection fan-out and cascade deployments

You can use a *fan-out* deployment to extend data protection to multiple secondary systems. You can use a *cascade* deployment to extend data protection to tertiary systems.

Both fan-out and cascade deployments support any combination of SnapMirror DR, SnapVault, or unified replication. Beginning with ONTAP 9.5, SnapMirror synchronous relationships support fan-out deployments with one or more SnapMirror asynchronous relationships. Only one relationship in the fan-out configuration can be a SnapMirror synchronous relationship, all the other relationships from the source volume must be SnapMirror asynchronous relationships. SnapMirror synchronous relationships also support cascade deployments (beginning with ONTAP 9.6); however, the relationship from the destination volume of the SnapMirror synchronous relationship must be a SnapMirror asynchronous relationship. SnapMirror active sync (supported beginning with ONTAP 9.13.1) also supports fan-out configurations.

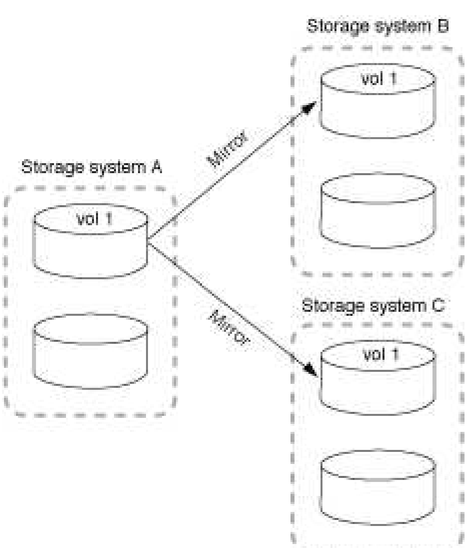
> You can use a *fan-in* deployment to create data protection relationships between multiple primary systems and a single secondary system. Each relationship must use a different volume on the secondary system.

> You should be aware that volumes that are part of a fan-out or cascade configuration can take longer to
> resynchronize. It is not uncommon to see the SnapMirror relationship reporting
> the status "preparing" for an extended time period.

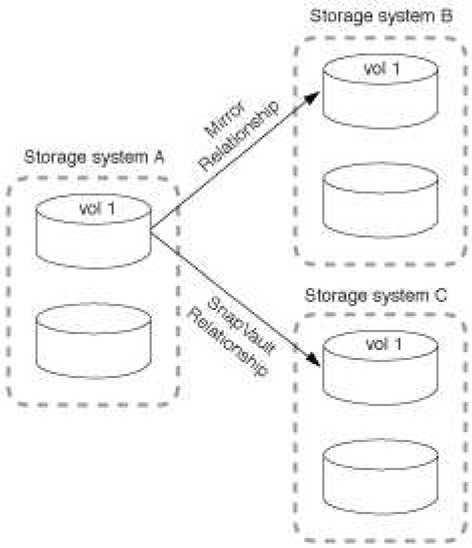
How fan-out deployments work

SnapMirror supports *multiple-mirrors* and *mirror-vault* fan-out deployments.

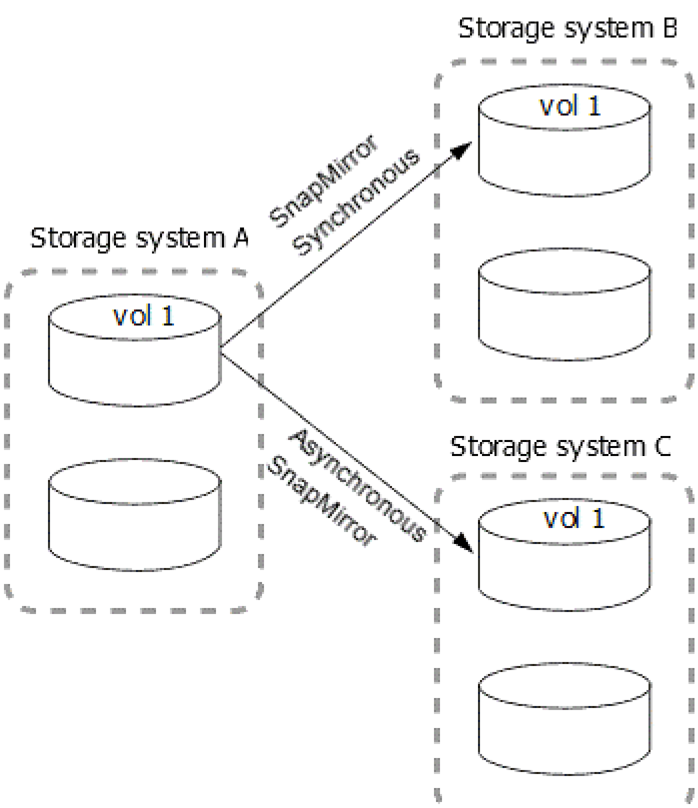
A multiple-mirrors fan-out deployment consists of a source volume that has a mirror relationship to multiple secondary volumes.



A mirror-vault fan-out deployment consists of a source volume that has a mirror relationship to a secondary volume and a SnapVault relationship to a different secondary volume.



Beginning with ONTAP 9.5, you can have fan-out deployments with SnapMirror synchronous relationships; however, only one relationship in the fan-out configuration can be a SnapMirror synchronous relationship, all the other relationships from the source volume must be SnapMirror asynchronous relationships.

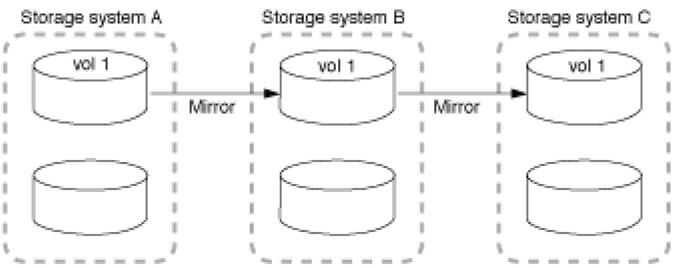


How cascade deployments work

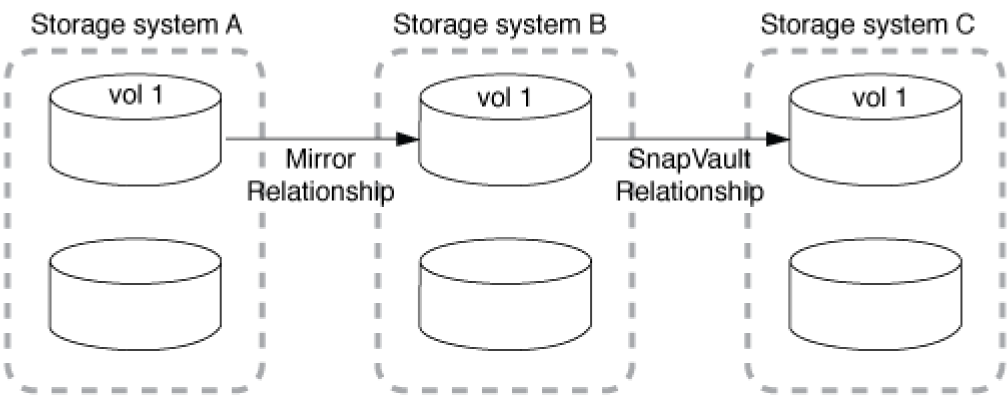
SnapMirror supports *mirror-mirror*, *mirror-vault*, *vault-mirror*, and *vault-vault* cascade deployments.

A mirror-mirror cascade deployment consists of a chain of relationships in which a source volume is mirrored to a secondary volume, and the secondary volume is mirrored to a tertiary volume. If the secondary volume becomes unavailable, you can synchronize the relationship between the primary and tertiary volumes without performing a new baseline transfer.

Beginning with ONTAP 9.6, SnapMirror synchronous relationships are supported in a mirror-mirror cascade deployment. Only the primary and secondary volumes can be in a SnapMirror synchronous relationship. The relationship between the secondary volumes and tertiary volumes must be asynchronous.



A mirror-vault cascade deployment consists of a chain of relationships in which a source volume is mirrored to a secondary volume, and the secondary volume is vaulted to a tertiary volume.



Vault-mirror and vault-vault cascade deployments are also supported:

- A vault-mirror cascade deployment consists of a chain of relationships in which a source volume is vaulted to a secondary volume, and the secondary volume is mirrored to a tertiary volume.
- A vault-vault cascade deployment consists of a chain of relationships in which a source volume is vaulted to a secondary volume, and the secondary volume is vaulted to a tertiary volume.

Learn about ONTAP SnapMirror licensing

Beginning with ONTAP 9.3, licensing has been simplified for replicating between ONTAP instances. In ONTAP 9 releases, the SnapMirror license supports both vault and mirror relationships. You can use a SnapMirror license to support ONTAP replication for both backup and disaster recovery use cases.

Prior to the ONTAP 9.3 release, a separate SnapVault license was needed to configure *vault* relationships between ONTAP instances, where the DP instance could retain a higher number of snapshots to support backup use cases with longer retention times, and a SnapMirror license was needed to configure *mirror* relationships between ONTAP instances, where each ONTAP instance would maintain the same number of snapshots (that is, a *mirror* image) to support disaster recovery use cases to make cluster failovers possible. Both SnapMirror and SnapVault licenses continue to be used and supported for ONTAP 8.x and 9.x releases.

While SnapVault licenses continue to function and are supported for both ONTAP 8.x and 9.x releases, the SnapMirror license can be used in place of a SnapVault license and can be used for both mirror and vault configurations.

For ONTAP asynchronous replication, beginning with ONTAP 9.3 a single unified replication engine is used to configure extended data protection mode (XDP) policies, where the SnapMirror license can be configured for a mirror policy, a vault policy, or a mirror-vault policy. A SnapMirror license is required on both the source and destination clusters. A SnapVault license is not required if a SnapMirror license is already installed. The SnapMirror asynchronous perpetual license is included in the ONTAP One software suite that's installed on new AFF and FAS systems.

Data protection configuration limits are determined using several factors, including your ONTAP version, hardware platform, and the licenses installed. For more information, see Hardware Universe.

SnapMirror synchronous license

Beginning with ONTAP 9.5, SnapMirror synchronous relationships are supported. You require the following licenses for creating a SnapMirror synchronous relationship:

- The SnapMirror synchronous license is required on both the source cluster and the destination cluster.

  The SnapMirror synchronous license is part of the ONTAP One license suite.

  If your system was purchased before June 2019 with a Premium or Flash Bundle, you can download a NetApp master key to get the required SnapMirror synchronous license from the NetApp Support Site: Master License Keys.

- The SnapMirror license is required on both the source cluster and the destination cluster.

SnapMirror cloud license

Beginning with ONTAP 9.8, the SnapMirror cloud license provides asynchronous replication of snapshots from ONTAP instances to object storage endpoints. Replication targets can be configured using both on-premises object stores as well as S3 and S3-compatible public cloud object storage services. SnapMirror cloud relationships are supported from ONTAP systems to pre-qualified object storage targets.

SnapMirror cloud is not available as a standalone license. Only one license is needed per ONTAP cluster. In addition to a SnapMirror cloud license, the SnapMirror asynchronous license is also required.

You require the following licenses for creating a SnapMirror cloud relationship:

- Both a SnapMirror license and a SnapMirror cloud license for replicating directly to the object store endpoint.
- When configuring a multi-policy replication workflow (for example, Disk-to-Disk-to-Cloud), a SnapMirror license is required on all ONTAP instances, while the SnapMirror cloud license is only required for the source cluster which is replicating directly to the object storage endpoint.

Beginning with ONTAP 9.9.1, you can use System Manager for SnapMirror cloud replication.

A list of authorized SnapMirror cloud third-party applications is published on the NetApp web site.

Data Protection Optimized license

Data Protection Optimized (DPO) licenses are no longer being sold, and DPO is not supported on current platforms; however, if you have a DPO license installed on a supported platform, NetApp continues to provide support until the end of availability of that platform.

DPO is not included with the ONTAP One license bundle, and you cannot upgrade to the ONTAP One license bundle if the DPO license is installed on a system.

For information about supported platforms, see Hardware Universe.

ONTAP DPO systems feature enhancements

Beginning with ONTAP 9.6, the maximum number of FlexVol volumes supported increases when the DP_Optimized (DPO) license is installed. Beginning with ONTAP 9.4, systems with the DPO license support SnapMirror backoff, cross-volume background deduplication, use of snapshot blocks as donors, and compaction.

Beginning with ONTAP 9.6, the maximum supported number of FlexVol volumes on secondary or data protection systems has increased, enabling you to scale up to 2,500 FlexVol volumes per node, or up to 5,000 in failover mode. The increase in FlexVol volumes is enabled with the DP_Optimized (DPO) license. A SnapMirror license is still required on both the source and destination nodes.

Beginning with ONTAP 9.4, the following feature enhancements are made to DPO systems:

- SnapMirror backoff: In DPO systems, replication traffic is given the same priority that client workloads are given.

  SnapMirror backoff is disabled by default on DPO systems.

- Volume background deduplication and cross-volume background deduplication: Volume background deduplication and cross-volume background deduplication are enabled in DPO systems.

  You can run the `storage aggregate efficiency cross-volume-dedupe start -aggregate` *`aggregate_name`* `-scan-old-data true` command to deduplicate the existing data. The best practice is to run the command during off-peak hours to reduce the impact on performance.

  Learn more about `storage aggregate efficiency cross-volume-dedupe start` in the ONTAP command reference.

- Increased savings by using snapshot blocks as donors: The data blocks that are not available in the active file system but are trapped in snapshots are used as donors for volume deduplication.

  The new data can be deduplicated with the data that was trapped in snapshots, effectively sharing the snapshot blocks as well. The increased donor space provides more savings, especially when the volume has a large number of snapshots.

- Compaction: Data compaction is enabled by default on DPO volumes.

Learn about path name pattern matching in ONTAP SnapMirror commands

You can use pattern matching to specify the source and destination paths in `snapmirror` commands.

`snapmirror` commands use fully qualified path names in the following format: `vserver:volume`. You can abbreviate the path name by not entering the SVM name. If you do this, the `snapmirror` command assumes the local SVM context of the user.

Assuming that the SVM is called “vserver1” and the volume is called “vol1”, the fully qualified path name is `vserver1:vol1`.

You can use the asterisk (*) in paths as a wildcard to select matching, fully qualified path names. The following table provides examples of using the wildcard to select a range of volumes.

`*`	Matches all paths.
`vs*`	Matches all SVMs and volumes with SVM names beginning with `vs`.
`:*src`	Matches all SVMs with volume names containing the `src` text.
`:vol`	Matches all SVMs with volume names beginning with `vol`.

```
vs1::> snapmirror show -destination-path *:*dest*

Progress

              DP   vs2:sm_dest1
                                Snapmirrored  Idle           -
true    -
```

Learn more about `snapmirror show` in the ONTAP command reference.

Learn about extended queries for ONTAP SnapMirror relationship operations

You can use *extended queries* to perform SnapMirror operations on many SnapMirror relationships at one time. For example, you might have multiple uninitialized SnapMirror relationships that you want to initialize using one command.

About this task

You can apply extended queries to the following SnapMirror operations:

- Initializing uninitialized relationships
- Resuming quiesced relationships
- Resynchronizing broken relationships

* Updating idle relationships
* Aborting relationship data transfers

Step

1. Perform a SnapMirror operation on many relationships:

   `snapmirror command {-state state } *`

   The following command initializes SnapMirror relationships that are in an `Uninitialized` state:

   ```
   vs1::> snapmirror initialize {-state Uninitialized} *
   ```

   Learn more about `snapmirror initialize` in the ONTAP command reference.

Compatible ONTAP versions for SnapMirror relationships

The source and destination volumes must be running compatible ONTAP versions before creating a SnapMirror data protection relationship. Before you upgrade ONTAP, you should verify that your current ONTAP version is compatible with your target ONTAP version for SnapMirror relationships.

Unified replication relationships

For SnapMirror relationships of type "XDP", using on premises or Cloud Volumes ONTAP releases:

Beginning with ONTAP 9.9.0:

* ONTAP 9.x.0 releases are cloud-only releases and support Cloud Volumes ONTAP systems. The asterisk (*) after the release version indicates a cloud-only release.

  > ONTAP 9.16.0 is an exception to the cloud-only rule because it provides support for ASA r2 systems. The plus sign (+) after the release version indicates an ASA r2 supported release. ASA r2 systems support SnapMirror relationships only to other ASA r2 systems.

* ONTAP 9.x.1 releases are general releases and support both on-premises and Cloud Volumes ONTAP systems.

> When advanced capacity balancing is enabled on volumes in clusters running ONTAP 9.16.1 or later, SnapMirror transfers are not supported to clusters running ONTAP versions earlier than ONTAP 9.16.1.

> Interoperability is bidirectional.

SnapMirror SVM disaster recovery relationships

For SVM disaster recovery data and SVM protection:

SVM disaster recovery is supported only between clusters running the same version of ONTAP. **Version-independence is not supported for SVM replication**.

For SVM disaster recovery for SVM migration:

- Replication is supported in a single direction from an earlier version of ONTAP on the source to the same or later version of ONTAP on the destination.
- The ONTAP version on the target cluster must be no more than two major on-premises versions newer or two major cloud versions newer (beginning with ONTAP 9.9.0), as shown in the table below.
    - Replication is not supported for long-term data protection use cases.

The asterisk (*) after the release version indicates a cloud-only release.

To determine support, locate the source version in the left table column, and then locate the destination version on the top row (DR/Migration for like versions and Migration only for newer versions).

Source	**Destination**																					
	9.4	9.5	9.6	9.7	9.8	9.9.0*	9.9.1	9.10.0*	9.10.1	9.11.0*	9.11.1	9.12.0*	9.12.1	9.13.0*	9.13.1	9.14.0*	9.14.1	9.15.0*	9.15.1	9.16.0	9.16.1	9.17.1

SnapMirror disaster recovery relationships

For SnapMirror relationships of type “DP” and policy type “async-mirror”:

> DP-type mirrors cannot be initialized beginning with ONTAP 9.11.1 and are completely deprecated in ONTAP 9.12.1. For more information, see Deprecation of data protection SnapMirror relationships.

> In the following table, the column on the left indicates the ONTAP version on the source volume, and the top row indicates the ONTAP versions you can have on your destination volume.

Source	Destination								
	9.11.1	9.10.1	9.9.1	9.8	9.7	9.6	9.5	9.4	9.3
9.11.1	Yes	No	No	No	No	No	No	No	No
9.10.1	Yes	Yes	No	No	No	No	No	No	No
9.9.1	Yes	Yes	Yes	No	No	No	No	No	No
9.8	No	Yes	Yes	Yes	No	No	No	No	No
9.7	No	No	Yes	Yes	Yes	No	No	No	No
9.6	No	No	No	Yes	Yes	Yes	No	No	No
9.5	No	No	No	No	Yes	Yes	Yes	No	No
9.4	No	No	No	No	No	Yes	Yes	Yes	No
9.3	No	No	No	No	No	No	Yes	Yes	Yes

Interoperability is not bidirectional.

Learn about ONTAP SnapMirror limitations

You should be aware of basic SnapMirror limitations before creating a data protection relationship.

- A destination volume can have only one source volume.

  A source volume can have multiple destination volumes. The destination volume can be the source volume for any type of SnapMirror replication relationship.

- Depending on the array model, you can fan out a maximum of eight or sixteen destination volumes from a single source volume. See the Hardware Universe to learn details for your specific configuration.
- You cannot restore files to the destination of a SnapMirror DR relationship.
- Source or destination SnapVault volumes cannot be 32-bit.
- The source volume for a SnapVault relationship should not be a FlexClone volume.

  The relationship will work, but the efficiency offered by FlexClone volumes will not be preserved.

Configure SnapMirror volume replication

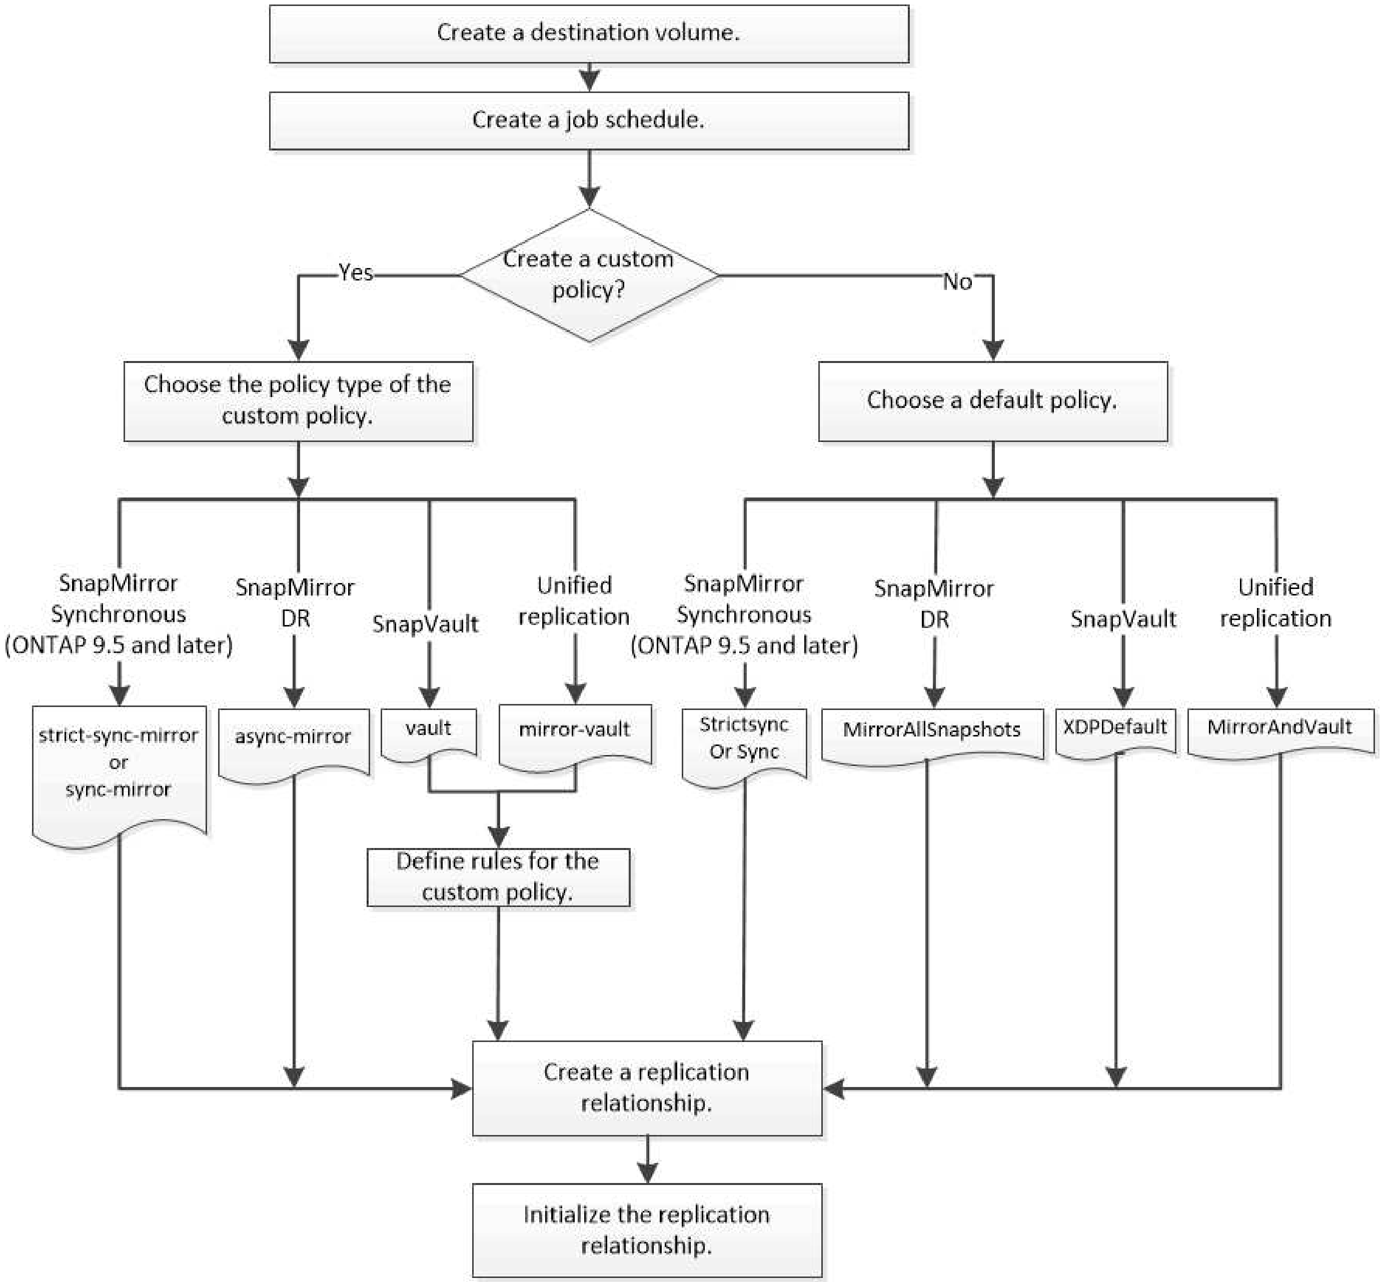
ONTAP SnapMirror replication workflow

SnapMirror offers three types of data protection relationship: SnapMirror DR, archive (previously known as SnapVault), and unified replication. You can follow the same basic workflow to configure each type of relationship.

Beginning with general availability in ONTAP 9.9.1, SnapMirror active sync provides Zero Recovery Time Objective (Zero RTO) or Transparent Application Failover (TAF) to enable automatic failover of business-critical applications in SAN environments.

For each type of SnapMirror data protection relationship, the workflow is the same: create a destination volume, create a job schedule, specify a policy, create and initialize the relationship.

Beginning with ONTAP 9.3, you can use the `snapmirror protect` command to configure a data protection relationship in a single step. Even if you use `snapmirror protect`, you need to understand each step in the workflow.



Related information

- snapmirror protect

Configure an ONTAP SnapMirror replication relationship in one step

Beginning with ONTAP 9.3, you can use the `snapmirror protect` command to configure a data protection relationship in a single step. You specify a list of volumes to be replicated, an SVM on the destination cluster, a job schedule, and a SnapMirror policy. `snapmirror protect` does the rest.

Before you begin

- The source and destination clusters and SVMs must be peered.

  Cluster and SVM peering

- The language on the destination volume must be the same as the language on the source volume.

About this task

The `snapmirror protect` command chooses an aggregate associated with the specified SVM. If no aggregate is associated with the SVM, it chooses from all the aggregates in the cluster. The choice of aggregate is based on the amount of free space and the number of volumes on the aggregate.

The `snapmirror protect` command then performs the following steps:

- Creates a destination volume with an appropriate type and amount of reserved space for each volume in the list of volumes to be replicated.
- Configures a replication relationship appropriate for the policy you specify.
- Initializes the relationship.

The name of the destination volume is of the form *`source_volume_name_dst`*. In case of a conflict with an existing name, the command appends a number to the volume name. You can specify a prefix and/or suffix in the command options. The suffix replaces the system-supplied `dst` suffix.

In ONTAP 9.4 and later, a destination volume can contain up to 1019 snapshots.
In ONTAP 9.3 and earlier, a destination volume can contain up to 251 snapshots.

> Initialization can be time-consuming. `snapmirror protect` does not wait for initialization to complete before the job finishes. For this reason, you should use the `snapmirror show` command rather than the `job show` command to determine when initialization is complete.

Beginning with ONTAP 9.5, SnapMirror synchronous relationships can be created by using the `snapmirror protect` command.

Learn more about `snapmirror protect` in the [ONTAP command reference].

Step

1. Create and initialize a replication relationship in one step:

   You must replace the variables in angle brackets with the required values before running this command.

   ```
   snapmirror protect -path-list <SVM:volume> -destination-vserver
   <destination_SVM> -policy <policy> -schedule <schedule> -auto-initialize
   <true|false> -destination-volume-prefix <prefix> -destination-volume
   -suffix <suffix>
   ```

   > You must run this command from the destination SVM or the destination cluster. The `-auto -initialize` option defaults to “true”.

   The following example creates and initializes a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB
-destination-vserver svm_backup -policy MirrorAllSnapshots -schedule
replication_daily
```

You can use a custom policy if you prefer. For more information, see Creating a custom replication policy.

The following example creates and initializes a SnapVault relationship using the default `XDPDefault` policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB
-destination-vserver svm_backup -policy XDPDefault -schedule
replication_daily
```

The following example creates and initializes a unified replication relationship using the default `MirrorAndVault` policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB
-destination-vserver svm_backup -policy MirrorAndVault
```

The following example creates and initializes a SnapMirror synchronous relationship using the default `Sync` policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB
-destination-vserver svm_sync -policy Sync
```

For SnapVault and unified replication policies, you might find it useful to define a schedule for creating a copy of the last transferred snapshot on the destination. For more information, see Defining a schedule for creating a local copy on the destination.

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created.

Learn more about `snapmirror show` in the ONTAP command reference.

Related information

- job show

Configure a replication relationship one step at a time

Create an ONTAP SnapMirror destination volume

You can use the `volume create` command on the destination to create a destination volume. The destination volume should be the same or greater in size than the source volume. Learn more about `volume create` in the ONTAP command reference.

Step

1. Create a destination volume:

   `volume create -vserver SVM -volume volume -aggregate aggregate -type DP -size size`

   The following example creates a 2-GB destination volume named `volA_dst`:

   ```
   cluster_dst::> volume create -vserver SVM_backup -volume volA_dst
   -aggregate node01_aggr -type DP -size 2GB
   ```

Create an ONTAP SnapMirror replication job schedule

The job schedule determines when SnapMirror automatically updates the data protection relationship to which the schedule is assigned. You can use System Manager or the `job schedule cron create` command to create a replication job schedule. Learn more about `job schedule cron create` in the ONTAP command reference.

About this task

You assign a job schedule when you create a data protection relationship. If you do not assign a job schedule, you must update the relationship manually.

Steps

You can create a replication job schedule using System Manager or the ONTAP CLI.

System Manager

1. Navigate to **Protection > Overview** and and expand **Local policy settings**.
2. In the **Schedules** pane, click →.
3. In the **Schedules** window, click + Add.
4. In the **Add schedule** window, enter the schedule name, and choose the context and schedule type.
5. Click **Save**.

CLI

1. Create a job schedule:

```
job schedule cron create -name <job_name> -month <month> -dayofweek
<day_of_week> -day <day_of_month> -hour <hour> -minute <minute>
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name <job_name> -vserver <Vserver_name>
-month <month> -dayofweek <day_of_week> -day <day_of_month> -hour
<hour> -minute <minute>
```

> The minimum supported schedule (RPO) for FlexVol volumes in a volume SnapMirror relationship is 5 minutes. The minimum supported schedule (RPO) for FlexGroup volumes in a volume SnapMirror relationship is 30 minutes.

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek
"Saturday" -hour 3 -minute 0
```

Customize a SnapMirror replication policy

Create a custom ONTAP SnapMirror replication policy

You can create a custom replication policy if the default policy for a relationship is not suitable. You might want to compress data in a network transfer, for example, or modify the number of attempts SnapMirror makes to transfer snapshots.

You can use a default or custom policy when you create a replication relationship. For a custom archive (formerly SnapVault) or unified replication policy, you must define one or more *rules* that determine which snapshots are transferred during initialization and update. You might also want to define a schedule for creating local snapshots on the destination.

The *policy type* of the replication policy determines the type of relationship it supports. The table below shows the available policy types.

Policy type	Relationship type
async-mirror	SnapMirror DR
vault	SnapVault
mirror-vault	Unified replication
strict-sync-mirror	SnapMirror synchronous in the StrictSync mode (supported beginning with ONTAP 9.5)
sync-mirror	SnapMirror synchronous in the Sync mode (supported beginning with ONTAP 9.5)

When you create a custom replication policy, it is a good idea to model the policy after a default policy.

Steps

You can create custom data protection policies with System Manager or the ONTAP CLI. Beginning with ONTAP 9.11.1, you can use System Manager to create custom mirror and vault policies, and to display and select legacy policies. This capability is also available in ONTAP 9.8P12 and later patches of ONTAP 9.8.

Create custom protection policies on both the source and destination cluster.

System Manager

1. Click **Protection > Overview > Local Policy Settings**.
2. Under **Protection Policies**, click →.
3. In the **Protection Policies** pane, click + Add.
4. Enter the new policy name, and select the policy scope.
5. Choose a policy type. To add a vault-only or mirror-only policy, choose **Asynchronous**, and click **Use a legacy policy type**.
6. Complete the required fields.
7. Click **Save**.
8. Repeat these steps on the other cluster.

CLI

1. Create a custom replication policy:

```
snapmirror policy create -vserver <SVM> -policy _policy_ -type
<async-mirror|vault|mirror-vault|strict-sync-mirror|sync-mirror>
-comment <comment> -tries <transfer_tries> -transfer-priority
<low|normal> -is-network-compression-enabled <true|false>
```

Beginning with ONTAP 9.5, you can specify the schedule for creating a common snapshot schedule for SnapMirror synchronous relationships by using the `-common-snapshot-schedule` parameter. By default, the common snapshot schedule for SnapMirror synchronous relationships is one hour. You can specify a value from 30 minutes to two hours for the snapshot schedule for SnapMirror synchronous relationships.

The following example creates a custom replication policy for SnapMirror DR that enables network compression for data transfers:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy
DR_compressed -type async-mirror -comment "DR with network
compression enabled" -is-network-compression-enabled true
```

The following example creates a custom replication policy for SnapVault:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy
my_snapvault -type vault
```

The following example creates a custom replication policy for unified replication:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy
my_unified -type mirror-vault
```

The following example creates a custom replication policy for SnapMirror synchronous relationship in the StrictSync mode:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy
my_strictsync -type strict-sync-mirror -common-snapshot-schedule
my_sync_schedule
```

Learn more about `snapmirror policy create` in the ONTAP command reference.

After you finish

For "vault" and "mirror-vault" policy types, you must define rules that determine which snapshots are transferred during initialization and update.

Use the `snapmirror policy show` command to verify that the SnapMirror policy was created.

Learn more about `snapmirror policy show` in the ONTAP command reference.

Define a rule for an ONTAP SnapMirror policy

For custom policies with the `vault` or `mirror-vault` policy type, you must define at least one rule that determines which snapshots are transferred during initialization and update. You can also define rules for default policies with the `vault` or `mirror-vault` policy type.

About this task

Every policy with the `vault` or `mirror-vault` policy type must have a rule that specifies which snapshots to replicate. The rule `bi-monthly`, for example, indicates that only snapshots assigned the SnapMirror label `bi-monthly` should be replicated. You specify the SnapMirror label when you configure the snapshot policy on the source.

Each policy type is associated with one or more system-defined rules. These rules are automatically assigned to a policy when you specify its policy type. The table below shows the system-defined rules.

System-defined rule	Used in policy types	Result
sm_created	async-mirror, mirror-vault, Sync, StrictSync	A snapshot created by SnapMirror is transferred on initialization and update.
all_source_snapshots	async-mirror	New snapshots on the source are transferred on initialization and update.
daily	vault,mirror-vault	New snapshots on the source with the SnapMirror label `daily` are transferred on initialization and update.

weekly	vault,mirror-vault	New snapshots on the source with the SnapMirror label `weekly` are transferred on initialization and update.
monthly	mirror-vault	New snapshots on the source with the SnapMirror label `monthly` are transferred on initialization and update.
app_consistent	Sync, StrictSync	Snapshots with the SnapMirror label `app_consistent` on source are synchronously replicated to the destination. Supported beginning with ONTAP 9.7.

Except for the “async-mirror” policy type, you can specify additional rules as needed, for default or custom policies. For example:

- For the default `MirrorAndVault` policy, you might create a rule called `bi-monthly` to match snapshots on the source with the `bi-monthly` SnapMirror label.
- For a custom policy with the `mirror-vault` policy type, you might create a rule called `bi-weekly` to match snapshots on the source with the `bi-weekly` SnapMirror label.

Step

1. Define a rule for a policy:

   `snapmirror policy add-rule -vserver` *`SVM`* `-policy` *`policy_for_rule`* `-snapmirror -label` *`snapmirror-label`* `-keep` *`retention_count`*

   The following example adds a rule with the SnapMirror label `bi-monthly` to the default `MirrorAndVault` policy:

   ```
   cluster_dst::> snapmirror policy add-rule -vserver svm1 -policy
   MirrorAndVault -snapmirror-label bi-monthly -keep 6
   ```

   The following example adds a rule with the SnapMirror label `bi-weekly` to the custom `my_snapvault` policy:

   ```
   cluster_dst::> snapmirror policy add-rule -vserver svm1 -policy
   my_snapvault -snapmirror-label bi-weekly -keep 26
   ```

   The following example adds a rule with the SnapMirror label `app_consistent` to the custom `Sync` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svm1 -policy Sync
-snapmirror-label app_consistent -keep 1
```

Learn more about `snapmirror policy add-rule` in the ONTAP command reference.

You can then replicate snapshots from the source cluster that match this SnapMirror label:

```
cluster_src::> snapshot create -vserver vs1 -volume vol1 -snapshot
snapshot1 -snapmirror-label app_consistent
```

Define an ONTAP SnapMirror schedule to create a local copy on the destination

For SnapVault and unified replication relationships, you can protect against the possibility that an updated snapshot is corrupted by creating a copy of the last transferred snapshot on the destination. This "local copy" is retained regardless of the retention rules on the source, so that even if the snapshot originally transferred by SnapMirror is no longer available on the source, a copy of it will be available on the destination.

About this task

You specify the schedule for creating a local copy in the `-schedule` option of the `snapmirror policy add-rule` command.

Step

1. Define a schedule for creating a local copy on the destination:

   `snapmirror policy add-rule -vserver` *`SVM`* `-policy` *`policy_for_rule`* `-snapmirror -label` *`snapmirror-label`* `-schedule` *`schedule`*

   For an example of how to create a job schedule, see Creating a replication job schedule.

   The following example adds a schedule for creating a local copy to the default `MirrorAndVault` policy:

   ```
   cluster_dst::> snapmirror policy add-rule -vserver svm1 -policy
   MirrorAndVault -snapmirror-label my_monthly -schedule my_monthly
   ```

   The following example adds a schedule for creating a local copy to the custom `my_unified` policy:

   ```
   cluster_dst::> snapmirror policy add-rule -vserver svm1 -policy
   my_unified -snapmirror-label my_monthly -schedule my_monthly
   ```

   Learn more about `snapmirror policy add-rule` in the ONTAP command reference.

Create an ONTAP SnapMirror replication relationship

The relationship between the source volume in primary storage and the destination volume in secondary storage is called a *data protection relationship.* You can use the `snapmirror create` command to create SnapMirror DR, SnapVault, or unified replication data protection relationships.

> This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to create a replication relationship. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

Beginning with ONTAP 9.11.1, you can use System Manager to select pre-created and custom mirror and vault policies, to display and select legacy policies, and to override the transfer schedules defined in a protection policy when protecting volumes and storage VMs. This capability is also available in ONTAP 9.8P12 and later patches of ONTAP 9.8.

> If you are using ONTAP 9.8P12 or later ONTAP 9.8 patch release and you configured SnapMirror using System Manager, you should use ONTAP 9.9.1P13 or later and ONTAP 9.10.1P10 or later patch releases if you plan to upgrade to ONTAP 9.9.1 or ONTAP 9.10.1 releases.

Before you begin

- The source and destination clusters and SVMs must be peered.

  Cluster and SVM peering

- The language on the destination volume must be the same as the language on the source volume.

About this task

Until ONTAP 9.3, SnapMirror invoked in DP mode and SnapMirror invoked in XDP mode used different replication engines, with different approaches to version-dependence:

- SnapMirror invoked in DP mode used a *version-dependent* replication engine in which the ONTAP version was required to be the same on primary and secondary storage:

```
cluster_dst::>  snapmirror create -type DP -source-path ... -destination
-path ...
```

- SnapMirror invoked in XDP mode used a *version-flexible* replication engine that supported different ONTAP versions on primary and secondary storage:

```
cluster_dst::>  snapmirror create -type XDP -source-path ...
-destination-path ...
```

With improvements in performance, the significant benefits of version-flexible SnapMirror outweigh the slight advantage in replication throughput obtained with version-dependent mode. For this reason, beginning with ONTAP 9.3, XDP mode has been made the new default, and any invocations of DP mode on the command line or in new or existing scripts are automatically converted to XDP mode.

Existing relationships are not affected. If a relationship is already of type DP, it will continue to be of type DP. The table below shows the behavior you can expect.

If you specify…	The type is…	The default policy (if you do not specify a policy) is…
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAllSnapshots (SnapMirror DR)
XDP	XDP	XDPDefault (SnapVault)

See also the examples in the procedure below.

The only exceptions to conversion are as follows:

- SVM data protection relationships continue to default to DP mode.

  Specify XDP explicitly to obtain XDP mode with the default `MirrorAllSnapshots` policy.
- Load-sharing data protection relationships continue to default to DP mode.
- SnapLock data protection relationships continue to default to DP mode.
- Explicit invocations of DP continue to default to DP mode if you set the following cluster-wide option:

  ```
  options replication.create_data_protection_rels.enable on
  ```

  This option is ignored if you do not explicitly invoke DP.

Beginning with ONTAP 9.14.1, the `-backoff-level` option is added to the `snapmirror create`, `snapmirror modify`, and `snapmirror restore` commands to enable you to specify the backoff level per relationship. The option is supported only with FlexVol SnapMirror relationships. The optional command specifies the SnapMirror backoff level due to client ops. Backoff values can be high, medium or none. The default value is high.

Beginning with ONTAP 9.5, SnapMirror synchronous relationships are supported.

In ONTAP 9.4 and later, a destination volume can contain up to 1019 snapshots.
In ONTAP 9.3 and earlier, a destination volume can contain up to 251 snapshots.

Steps

You can use System Manager or the ONTAP CLI to create a replication relationship.

System Manager

1. Select the volume or LUN to protect: click **Storage > Volumes** or **Storage > LUNs**, and then click the desired volume or LUN name.
2. Click Protect.
3. Select the destination cluster and storage VM.
4. The asynchronous policy is selected by default. To select a synchronous policy, click **More Options**.
5. Click **Protect**.
6. Click the **SnapMirror (Local or Remote)** tab for the selected volume or LUN to verify that protection is set up correctly.

CLI

1. From the destination cluster, create a replication relationship:

   You must replace the variables in angle brackets with the required values before running this command.

   ```
   snapmirror create -source-path <SVM:volume> -destination-path
   <SVM:volume> -type <DP|XDP> -schedule <schedule> -policy <policy>
   ```

   > The `schedule` parameter is not applicable when creating SnapMirror synchronous relationships.

   The following example creates a SnapMirror DR relationship using the default `MirrorLatest` policy:

   ```
   cluster_dst::> snapmirror create -source-path svm1:volA -destination
   -path svm_backup:volA_dst -type XDP -schedule my_daily -policy
   MirrorLatest
   ```

   The following example creates a SnapVault relationship using the default `XDPDefault` policy:

   ```
   cluster_dst::> snapmirror create -source-path svm1:volA -destination
   -path svm_backup:volA_dst -type XDP -schedule my_daily -policy
   XDPDefault
   ```

   The following example creates a unified replication relationship using the default `MirrorAndVault` policy:

   ```
   cluster_dst:> snapmirror create -source-path svm1:volA -destination
   -path svm_backup:volA_dst -type XDP -schedule my_daily -policy
   MirrorAndVault
   ```

The following example creates a unified replication relationship using the custom `my_unified` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy
my_unified
```

The following example creates a SnapMirror synchronous relationship using the default `Sync` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst -type XDP -policy Sync
```

The following example creates a SnapMirror synchronous relationship using the default `StrictSync` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst -type XDP -policy StrictSync
```

The following example creates a SnapMirror DR relationship. With the DP type automatically converted to XDP and with no policy specified, the policy defaults to the `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst -type DP -schedule my_daily
```

The following example creates a SnapMirror DR relationship. With no type or policy specified, the policy defaults to the `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst -schedule my_daily
```

The following example creates a SnapMirror DR relationship. With no policy specified, the policy defaults to the `XDPDefault` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst -type XDP -schedule my_daily
```

The following example creates a SnapMirror synchronous relationship with the predefined policy `SnapCenterSync`:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst -type XDP -policy SnapCenterSync
```

> The predefined policy `SnapCenterSync` is of type `Sync`. This policy replicates any snapshot that is created with the `snapmirror-label` of "app_consistent".

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created.

Learn more about `snapmirror show` in the ONTAP command reference.

To perform these tasks with…	See this content…
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume backup using SnapVault overview

Related information

- snapmirror create

Initialize an ONTAP SnapMirror replication relationship

For all relationship types, initialization performs a *baseline transfer*: it makes a snapshot of the source volume, then transfers that copy and all the data blocks it references to the destination volume. Otherwise, the contents of the transfer depend on the policy.

Before you begin

The source and destination clusters and SVMs must be peered.

Cluster and SVM peering

About this task

Initialization can be time-consuming. You might want to run the baseline transfer in off-peak hours.

Beginning with ONTAP 9.5, SnapMirror synchronous relationships are supported.

You should be aware that if a filesystem is rebooted for any reason, such as a node reboot, takeover/giveback, or panic, then initialization will not automatically resume and must be restarted manually.

Step

1. Initialize a replication relationship:

   ```
   snapmirror initialize -source-path <SVM:volume>|<cluster://SVM/volume>, …
   -destination-path <SVM:volume>|<cluster://SVM/volume>, …
   ```

You must run this command from the destination SVM or the destination cluster.

The following example initializes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror initialize -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

Learn more about `snapmirror initialize` in the ONTAP command reference.

Ensure a common snapshot in an ONTAP mirror-vault deployment

You can use the `snapmirror snapshot-owner create` command to preserve a labeled snapshot on the secondary in a mirror-vault deployment. Doing so ensures that a common snapshot exists for the update of the vault relationship.

About this task

If you use a combination mirror-vault fan-out or cascade deployment, you should keep in mind that updates will fail if a common snapshot does not exist on the source and destination volumes.

This is never an issue for the mirror relationship in a mirror-vault fan-out or cascade deployment, since SnapMirror always creates a snapshot of the source volume before it performs the update.

It might be an issue for the vault relationship, however, because SnapMirror does not create a snapshot of the source volume when it updates a vault relationship. You need to use the `snapmirror snapshot-owner create` to ensure that there is at least one common snapshot on both the source and destination of the vault relationship. Learn more about data protection fan-out and cascade deployments.

Steps

1. On the source volume, assign an owner to the labeled snapshot you want to preserve:

   ```
   snapmirror snapshot-owner create -vserver <SVM> -volume <volume> -snapshot
   <snapshot> -owner <owner>
   ```

   The following example assigns `ApplicationA` as the owner of the `snap1` snapshot:

   ```
   clust1::> snapmirror snapshot-owner create -vserver vs1 -volume vol1
   -snapshot snap1 -owner ApplicationA
   ```

   Learn more about `snapmirror snapshot-owner create` in the ONTAP command reference.

2. Update the mirror relationship, as described in Updating a replication relationship manually.

   Alternatively, you can wait for the scheduled update of the mirror relationship.

3. Transfer the labeled snapshot to the vault destination:

   ```
   snapmirror update -source-path <SVM:volume>|<cluster://SVM/volume>, …
   ```

`-destination-path <SVM:volume>|<cluster://SVM/volume>, … -source-snapshot snapshot`

The following example transfers the `snap1` snapshot

```
clust1::> snapmirror update -vserver vs1 -volume vol1
-source-snapshot snap1
```

The labeled snapshot will be preserved when the vault relationship is updated.

Learn more about `snapmirror update` in the ONTAP command reference.

4. On the source volume, remove the owner from the labeled snapshot:

   `snapmirror snapshot-owner delete -vserver` *`SVM`* `-volume` *`volume`* `-snapshot` *`snapshot`* `-owner` *`owner`*

   The following examples removes `ApplicationA` as the owner of the `snap1` snapshot:

   ```
   clust1::> snapmirror snapshot-owner delete -vserver vs1 -volume vol1
   -snapshot snap1 -owner ApplicationA
   ```

   Learn more about `snapmirror snapshot-owner delete` in the ONTAP command reference.

Example: Configure an ONTAP SnapMirror vault-vault cascade

An example will show in concrete terms how you can configure replication relationships one step at a time. You can use the vault-vault cascade deployment configured in the example to retain more than 251 snapshots labeled `my-weekly`.

Before you begin

The source and destination clusters and SVMs must be peered.

About this task

The example assumes the following:

- You have configured snapshots on the source cluster with the SnapMirror labels `my-daily`, `my-weekly`, and `my-monthly`.
- You have configured destination volumes named `volA` on the secondary and tertiary destination clusters.
- You have configured replication job schedules named `my_snapvault` on the secondary and tertiary destination clusters.

The example shows how to create replication relationships based on two custom policies:

- The `snapvault_secondary` policy retains 7 daily, 52 weekly, and 180 monthly snapshots on the secondary destination cluster.
- The `snapvault_tertiary policy` retains 250 weekly snapshots on the tertiary destination cluster.

Steps

1. On the secondary destination cluster, create the `snapvault_secondary` policy:

```
cluster_secondary::> snapmirror policy create -policy snapvault_secondary
-type vault -comment "Policy on secondary for vault to vault cascade" -vserver
svm_secondary
```

2. On the secondary destination cluster, define the `my-daily` rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary
-snapmirror-label my-daily -keep 7 -vserver svm_secondary
```

3. On the secondary destination cluster, define the `my-weekly` rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary
-snapmirror-label my-weekly -keep 52 -vserver svm_secondary
```

4. On the secondary destination cluster, define the `my-monthly` rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary
-snapmirror-label my-monthly -keep 180 -vserver svm_secondary
```

5. On the secondary destination cluster, verify the policy:

```
cluster_secondary::> snapmirror policy show snapvault_secondary -instance
```

```
                     Vserver: svm_secondary
       SnapMirror Policy Name: snapvault_secondary
       SnapMirror Policy Type: vault
                 Policy Owner: cluster-admin
                  Tries Limit: 8
            Transfer Priority: normal
    Ignore accesstime Enabled: false
      Transfer Restartability: always
  Network Compression Enabled: false
              Create Snapshot: false
                      Comment: Policy on secondary for vault to vault
cascade
        Total Number of Rules: 3
                   Total Keep: 239
                        Rules: SnapMirror Label     Keep  Preserve Warn
Schedule Prefix
                               ----------------     ----  -------- ----
-------- ------
                               my-daily                7  false       0 -
-
                               my-weekly              52  false       0 -
-
                               my-monthly            180  false       0 -
-
```

6. On the secondary destination cluster, create the relationship with the source cluster:

```
cluster_secondary::> snapmirror create -source-path svm_primary:volA
-destination-path svm_secondary:volA -type XDP -schedule my_snapvault -policy
snapvault_secondary
```

7. On the secondary destination cluster, initialize the relationship with the source cluster:

```
cluster_secondary::> snapmirror initialize -source-path svm_primary:volA
-destination-path svm_secondary:volA
```

8. On the tertiary destination cluster, create the `snapvault_tertiary` policy:

```
cluster_tertiary::> snapmirror policy create -policy snapvault_tertiary -type
vault -comment "Policy on tertiary for vault to vault cascade" -vserver
svm_tertiary
```

9. On the tertiary destination cluster, define the `my-weekly` rule for the policy:

```
cluster_tertiary::> snapmirror policy add-rule -policy snapvault_tertiary
-snapmirror-label my-weekly -keep 250 -vserver svm_tertiary
```

10. On the tertiary destination cluster, verify the policy:

```
cluster_tertiary::> snapmirror policy show snapvault_tertiary -instance
```

```
                    Vserver: svm_tertiary
        SnapMirror Policy Name: snapvault_tertiary
        SnapMirror Policy Type: vault
                 Policy Owner: cluster-admin
                  Tries Limit: 8
            Transfer Priority: normal
    Ignore accesstime Enabled: false
      Transfer Restartability: always
 Network Compression Enabled: false
              Create Snapshot: false
                      Comment: Policy on tertiary for vault to vault
cascade
        Total Number of Rules: 1
                   Total Keep: 250
                        Rules: SnapMirror Label     Keep  Preserve Warn
Schedule Prefix
                               ----------------     ----  -------- ----
-------- ------
                               my-weekly             250  false       0 -
-
```

11. On the tertiary destination cluster, create the relationship with the secondary cluster:

```
cluster_tertiary::> snapmirror create -source-path svm_secondary:volA
-destination-path svm_tertiary:volA -type XDP -schedule my_snapvault -policy
snapvault_tertiary
```

12. On the tertiary destination cluster, initialize the relationship with the secondary cluster:

```
cluster_tertiary::> snapmirror initialize -source-path svm_secondary:volA
-destination-path svm_tertiary:volA
```

Manage SnapMirror volume replication

Convert an existing ONTAP SnapMirror DP-type relationship to XDP

If you are upgrading to ONTAP 9.12.1 or later, you must convert DP-type relationships to

XDP before upgrading. ONTAP 9.12.1 and later does not support DP-type relationships. You can easily convert an existing DP-type relationship to XDP to take advantage of version-flexible SnapMirror.

Before upgrading to ONTAP 9.12.1, you must convert existing DP-type relationships to XDP before you can upgrade to ONTAP 9.12.1 and later releases.

About this task

- SnapMirror does not automatically convert existing DP-type relationships to XDP. To convert the relationship, you need to break and delete the existing relationship, create a new XDP relationship, and resync the relationship.
- When planning your conversion, you should be aware that background preparation and the data warehousing phase of an XDP SnapMirror relationship can take a long time. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

> After you convert a SnapMirror relationship type from DP to XDP, space-related settings, such as autosize and space guarantee are no longer replicated to the destination.

Steps

1. From the destination cluster, ensure that the SnapMirror relationship is type DP, that the mirror state is SnapMirrored, the relationship status is Idle, and the relationship is healthy:

   ```
   snapmirror show -destination-path <SVM:volume>
   ```

   The following example shows the output from the `snapmirror show` command:

```
cluster_dst::>snapmirror show -destination-path svm_backup:volA_dst

Source Path: svm1:volA
Destination Path: svm_backup:volA_dst
Relationship Type: DP
SnapMirror Schedule: -
Tries Limit: -
Throttle (KB/sec): unlimited
Mirror State: Snapmirrored
Relationship Status: Idle
Transfer Snapshot: -
Snapshot Progress: -
Total Progress: -
Snapshot Checkpoint: -
Newest Snapshot: snapmirror.10af643c-32d1-11e3-954b-
123478563412_2147484682.2014-06-27_100026
Newest Snapshot Timestamp: 06/27 10:00:55
Exported Snapshot: snapmirror.10af643c-32d1-11e3-954b-
123478563412_2147484682.2014-06-27_100026
Exported Snapshot Timestamp: 06/27 10:00:55
Healthy: true
```

> You might find it helpful to retain a copy of the `snapmirror show` command output to keep track existing of the relationship settings. Learn more about `snapmirror show` in the ONTAP command reference.

2. From the source and the destination volumes, ensure that both volumes have a common snapshot:

```
volume snapshot show -vserver <SVM> -volume <volume>
```

The following example shows the `volume snapshot show` output for the source and the destination volumes:

```
cluster_src:> volume snapshot show -vserver vsm1 -volume volA

27_100026
```

3. To ensure scheduled updates will not run during the conversion, quiesce the existing DP-type relationship:

```
snapmirror quiesce -source-path <SVM:volume> -destination-path
<SVM:volume>
```

ⓘ You must run this command from the destination SVM or the destination cluster.

The following example quiesces the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror quiesce -destination-path svm_backup:volA_dst
```

Learn more about `snapmirror quiesce` in the ONTAP command reference.

4. Break the existing DP-type relationship:

```
snapmirror break -destination-path <SVM:volume>
```

ⓘ You must run this command from the destination SVM or the destination cluster.

The following example breaks the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror break -destination-path svm_backup:volA_dst
```

Learn more about `snapmirror break` in the ONTAP command reference.

5. If automatic deletion of snapshots is enabled on the destination volume, disable it:

```
volume snapshot autodelete modify -vserver _SVM_ -volume _volume_
-enabled false
```

The following example disables snapshot autodelete on the destination volume `volA_dst`:

```
cluster_dst::> volume snapshot autodelete modify -vserver svm_backup
-volume volA_dst -enabled false
```

6. Delete the existing DP-type relationship:

```
snapmirror delete -destination-path <SVM:volume>
```

Learn more about `snapmirror-delete` in the ONTAP command reference.

You must run this command from the destination SVM or the destination cluster.

The following example deletes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror delete -destination-path svm_backup:volA_dst
```

7. Release the origin SVM disaster recovery relationship on the source:

```
snapmirror release -destination-path <SVM:volume> -relationship-info
-only true
```

The following example releases the SVM disaster recovery relationship:

```
cluster_src::> snapmirror release -destination-path svm_backup:volA_dst
-relationship-info-only true
```

Learn more about `snapmirror release` in the ONTAP command reference.

8. You can use the output you retained from the `snapmirror show` command to create the new XDP-type relationship:

```
snapmirror create -source-path <SVM:volume> -destination-path
<SVM:volume>  -type XDP -schedule <schedule> -policy <policy>
```

The new relationship must use the same source and destination volume. Learn more about the commands described in this procedure in the ONTAP command reference.

You must run this command from the destination SVM or the destination cluster.

The following example creates a SnapMirror disaster recovery relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup` using the default `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst
-type XDP -schedule my_daily -policy MirrorAllSnapshots
```

9. Resync the source and destination volumes:

```
snapmirror resync -source-path <SVM:volume> -destination-path
<SVM:volume>
```

To improve resync time, you can use the `-quick-resync` option, but you should be aware that storage efficiency savings can be lost.

> You must run this command from the destination SVM or the destination cluster. Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

Learn more about `snapmirror resync` in the ONTAP command reference.

10. If you disabled automatic deletion of snapshots, reenable it:

```
volume snapshot autodelete modify -vserver <SVM> -volume <volume>
-enabled true
```

After you finish

1. Use the `snapmirror show` command to verify that the SnapMirror relationship was created.

   Learn more about `snapmirror show` in the ONTAP command reference.

2. Once the SnapMirror XDP destination volume begins updating snapshots as defined by the SnapMirror policy, use the output of `snapmirror list-destinations` command from the source cluster to display the new SnapMirror XDP relationship.

Additional information about DP-type relationships

Beginning with ONTAP 9.3, XDP mode is the default, and any invocations of DP mode on the command line or in new or existing scripts are automatically converted to XDP mode.

Existing relationships are not affected. If a relationship is already of type DP, it will continue to be of type DP. Beginning with ONTAP 9.5, MirrorAndVault is the default policy when no data protection mode is specified or when XDP mode is specified as the relationship type. The table below shows the expected behavior.

If you specify…	The type is…	The default policy (if you do not specify a policy) is…
DP	XDP	MirrorAllSnapshots (SnapMirror DR)

Nothing	XDP	MirrorAndVault (unified replication)
XDP	XDP	MirrorAndVault (unified replication)

As the table shows, the default policies assigned to XDP in different circumstances ensure that the conversion maintains the functional equivalence of the previous types. Of course, you can use different policies as needed, including policies for unified replication:

If you specify…	And the policy is…	The result is…
DP	MirrorAllSnapshots	SnapMirror DR
	XDPDefault	SnapVault
	MirrorAndVault	Unified replication
XDP	MirrorAllSnapshots	SnapMirror DR
	XDPDefault	SnapVault
	MirrorAndVault	Unified replication

The only exceptions to conversion are as follows:

- SVM data protection relationships continue to default to DP mode in ONTAP 9.3 and earlier.

  Beginning with ONTAP 9.4, SVM data protection relationships default to XDP mode.

- Root volume load-sharing data protection relationships continue to default to DP mode.
- SnapLock data protection relationships continue to default to DP mode in ONTAP 9.4 and earlier.

  Beginning with ONTAP 9.5, SnapLock data protection relationships default to XDP mode.

- Explicit invocations of DP continue to default to DP mode if you set the following cluster-wide option:

  ```
  options replication.create_data_protection_rels.enable on
  ```

  This option is ignored if you do not explicitly invoke DP.

Convert the type of an ONTAP SnapMirror relationship

Beginning with ONTAP 9.5, SnapMirror synchronous is supported. You can convert an SnapMirror asynchronous relationship to a SnapMirror synchronous relationship or vice versa without performing a baseline transfer.

About this task

You cannot convert an SnapMirror asynchronous relationship to a SnapMirror synchronous relationship or vice versa by changing the SnapMirror policy.

Steps

- **Converting an SnapMirror asynchronous relationship to a SnapMirror synchronous relationship**
  a. From the destination cluster, delete the SnapMirror asynchronous relationship:

     `snapmirror delete -destination-path <SVM:volume>`

     ```
     cluster2::>snapmirror delete -destination-path vs1_dr:vol1
     ```

  b. From the source cluster, release the SnapMirror relationship without deleting the common snapshots:

     `snapmirror release -relationship-info-only true -destination-path <destination_SVM>:<destination_volume>`

     ```
     cluster1::>snapmirror release -relationship-info-only true
     -destination-path vs1_dr:vol1
     ```

  c. From the destination cluster, create a SnapMirror synchronous relationship:

     `snapmirror create -source-path` *`src_SVM:src_volume`* `-destination-path <destination_SVM>:<destination_volume> -policy sync-mirror`

     ```
     cluster2::>snapmirror create -source-path vs1:vol1 -destination-path
     vs1_dr:vol1 -policy sync
     ```

  d. Resynchronize the SnapMirror synchronous relationship:

     `snapmirror resync -destination-path <destination_SVM:destination_volume>`

     ```
     cluster2::>snapmirror resync -destination-path vs1_dr:vol1
     ```

- **Converting a SnapMirror synchronous relationship to an SnapMirror asynchronous relationship**
  a. From the destination cluster, quiesce the existing SnapMirror synchronous relationship:

     `snapmirror quiesce -destination-path <destination_SVM>:<destination_volume>`

```
cluster2::> snapmirror quiesce -destination-path vs1_dr:vol1
```

b. From the destination cluster, delete the SnapMirror asynchronous relationship:

`snapmirror delete -destination-path <SVM:volume>`

```
cluster2::>snapmirror delete -destination-path vs1_dr:vol1
```

c. From the source cluster, release the SnapMirror relationship without deleting the common snapshots:

`snapmirror release -relationship-info-only true -destination-path <destination_SVM:destination_volume>`

```
cluster1::>snapmirror release -relationship-info-only true
-destination-path vs1_dr:vol1
```

d. From the destination cluster, create an SnapMirror asynchronous relationship:

`snapmirror create -source-path` *`src_SVM:src_volume`* `-destination-path <destination_SVM:destination_volume> -policy MirrorAllSnapshots`

```
cluster2::>snapmirror create -source-path vs1:vol1 -destination-path
vs1_dr:vol1 -policy sync
```

e. Resynchronize the SnapMirror synchronous relationship:

`snapmirror resync -destination-path <destination_SVM:destination_volume>`

```
cluster2::>snapmirror resync -destination-path vs1_dr:vol1
```

Convert the mode of an ONTAP SnapMirror synchronous relationship

Beginning with ONTAP 9.5, SnapMirror synchronous relationships are supported. You can convert the mode of a SnapMirror synchronous relationship from StrictSync to Sync or vice versa.

About this task

You cannot modify the policy of a SnapMirror synchronous relationship to convert its mode.

Steps

1. From the destination cluster, quiesce the existing SnapMirror synchronous relationship:

   `snapmirror quiesce -destination-path <destination_SVM>:<destination_volume>`

   ```
   cluster2::> snapmirror quiesce -destination-path vs1_dr:vol1
   ```

2. From the destination cluster, delete the existing SnapMirror synchronous relationship:

   `snapmirror delete -destination-path <destination_SVM>:<destination_volume>`

   ```
   cluster2::> snapmirror delete -destination-path vs1_dr:vol1
   ```

3. From the source cluster, release the SnapMirror relationship without deleting the common snapshots:

   `snapmirror release -relationship-info-only true -destination-path <destination_SVM>:<destination_volume>`

   ```
   cluster1::> snapmirror release -relationship-info-only true -destination
   -path vs1_dr:vol1
   ```

4. From the destination cluster, create a SnapMirror synchronous relationship by specifying the mode to which you want to convert the SnapMirror synchronous relationship:

   `snapmirror create -source-path vs1:vol1 -destination-path <destination_SVM>:<destination_volume> -policy Sync|StrictSync`

   ```
   cluster2::> snapmirror create -source-path vs1:vol1 -destination-path
   vs1_dr:vol1 -policy Sync
   ```

5. From the destination cluster, resynchronize the SnapMirror relationship:

   `snapmirror resync -destination-path <destination_SVM>:<destination_volume>`

   ```
   cluster2::> snapmirror resync -destination-path vs1_dr:vol1
   ```

Create and delete ONTAP SnapMirror failover test volumes

Beginning with ONTAP 9.14.1, you can use System Manager to create a volume clone to test SnapMirror failover and disaster recovery without disrupting the active SnapMIrror relationship. When you finish testing, you can clean up the associated data and delete the test volume.

Create a SnapMirror failover test volume

About this task

* You can perform failover tests on synchronous and SnapMirror asynchronous relationships.
* A volume clone is created to perform the disaster recovery test.
* The clone volume is created on the same storage VM as the SnapMirror destination.
* You can use FlexVol and FlexGroup SnapMirror relationships.
* If a test clone already exists for the selected relationship, you cannot create another clone for that relationship.
* SnapLock vault relationships are not supported.

Before you begin

* You must be a cluster administrator.
* The SnapMirror license must be installed on the source and destination cluster.

Steps

1. On the destination cluster, select **Protection > Relationships**.
2. Select ⋮ next to the relationship source and choose **Test Failover**.
3. In the **Test Failover** window, select **Test Failover**.
4. Select **Storage > Volumes**, and verify that the test failover volume is listed.
5. Select **Storage > Shares**.
6. Select + Add and choose **Share**.
7. In the **Add share** window, type a name for the share in the **Share Name** field.
8. In the **Folder** field, select **Browse**, select the test clone volume, and **Save**.
9. At the bottom of the **Add share** window, choose **Save**.
10. In the **Storage > Shares** pane, locate the share you created and select ⌄ to view the share information.
11. Under **SMB/CIFS Access**, copy or make note of the access path for the share; for example, `\\123.456.7.890\failover_test`.
12. Use the SMB access path to open the share on the client and verify that the test volume has read and write capabilities.

Clean up failover data and delete the test volume

After you have completed failover testing, you can clean up all data associated with the test volume and delete it.

Steps

1. On the destination cluster, select **Protection > Relationships**.
2. Select ⋮ next to the relationship source and choose **Clean Up Test Failover**.
3. In the **Clean Up Test Failover** window, select **Clean Up**.
4. Select **Storage > Volumes** and verify that the test volume was deleted.

Serve data from a SnapMirror DR destination volume

Make the ONTAP SnapMirror destination volume writeable

You need to make the destination volume writeable before you can serve data from the volume to clients. To serve data from a mirror destination when a source becomes unavailable, stop scheduled transfers to the destination, and then break the SnapMirror relationship to make the destination writable.

About this task

You must perform this task from the destination SVM or the destination cluster.

Steps

You can use System Manager or the ONTAP CLI to make a destination volume writable.

System Manager

1. Select the protection relationship: click **Protection > Relationships**, and then click the desired volume name.
2. Click ⋮.
3. Stop scheduled transfers : click **Pause**.
4. Make the destination writable: click **Break**.
5. Go to the main **Relationships** page to verify that the relationship state displays as "broken off".

Next steps

You need to reverse resynchronize the replication relationship after you make a destination volume writeable.

When the disabled source volume is available again, you should reverse resynchronize the relationship again to copy the current data to the original source volume.

CLI

1. Stop scheduled transfers to the destination:

   ```
   snapmirror quiesce -source-path <SVM:volume|cluster://SVM/volume>
   -destination-path <SVM:volume|cluster://SVM/volume>
   ```

   The following example stops scheduled transfers between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

   ```
   cluster_dst::> snapmirror quiesce -source-path svm1:volA
   -destination-path svm_backup:volA_dst
   ```

   Learn more about `snapmirror quiesce` in the ONTAP command reference.

2. Stop ongoing transfers to the destination:

   ```
   snapmirror abort -source-path <SVM:volume|cluster://SVM/volume>
   -destination-path <SVM:volume|cluster://SVM/volume>
   ```

   > This step is not required for SnapMirror synchronous relationships (supported beginning with ONTAP 9.5).

   The following example stops ongoing transfers between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

   ```
   cluster_dst::> snapmirror abort -source-path svm1:volA -destination
   -path svm_backup:volA_dst
   ```

Learn more about `snapmirror abort` in the ONTAP command reference.

3. Break the SnapMirror DR relationship:

```
snapmirror break -source-path <SVM:volume|cluster://SVM/volume>
-destination-path <SVM:volume|cluster://SVM/volume>
```

The following example breaks the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

Learn more about `snapmirror break` in the ONTAP command reference.

Next steps

You need to resynchronize the replication relationship after you make a destination volume writeable.

Other ways to do this in ONTAP

To perform these tasks with…	See this content…
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery overview

Configure the ONTAP SnapMirror destination volume for data access

After making the destination volume writeable, you must configure the volume for data access. NAS clients, NVMe subsystem, and SAN hosts can access the data from the destination volume until the source volume is reactivated.

NAS environment:

1. Mount the NAS volume to the namespace using the same junction path that the source volume was mounted to in the source SVM.
2. Apply the appropriate ACLs to the SMB shares at the destination volume.
3. Assign the NFS export policies to the destination volume.
4. Apply the quota rules to the destination volume.
5. Redirect clients to the destination volume.
6. Remount the NFS and SMB shares on the clients.

SAN environment:

1. Map the LUNs in the volume to the appropriate initiator group.
2. For iSCSI, create iSCSI sessions from the SAN host initiators to the SAN LIFs.

3. On the SAN client, perform a storage re-scan to detect the connected LUNs.

For information about NVMe environment, see SAN administration.

Reactivate the original ONTAP SnapMirror source volume

You can reestablish the original data protection relationship between the source and destination volumes when you no longer need to serve data from the destination.

About this task

- The procedure below assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.
- Background preparation and the data warehousing phase of an XDP SnapMirror relationship can take a long time. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

Steps

1. Reverse the original data protection relationship:

   `snapmirror resync -source-path` *`SVM:volume`* `-destination-path` *`SVM:volume`*

   Learn more about `snapmirror resync` in the ONTAP command reference.

   > You must run this command from the original source SVM or the original source cluster. Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours. The command fails if a common snapshot does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship. Learn more about `snapmirror initialize` in the ONTAP command reference.

   The following example reverses the relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

   ```
   cluster_src::> snapmirror resync -source-path svm_backup:volA_dst
   -destination-path svm1:volA
   ```

2. When you are ready to reestablish data access to the original source, stop access to the original destination volume. One way to do this is to stop the original destination SVM:

   `vserver stop -vserver` *`SVM`*

   > You must run this command from the original destination SVM or the original destination cluster. This command stops user access to the entire original destination SVM. You may want to stop access to the original destination volume using other methods.

   The following example stops the original destination SVM:

```
cluster_dst::> vserver stop svm_backup
```

Learn more about `vserver stop` in the ONTAP command reference.

3. Update the reversed relationship:

   `snapmirror update -source-path` *`SVM:volume`* `-destination-path` *`SVM:volume`*

   > You must run this command from the original source SVM or the original source cluster.

   The following example updates the relationship between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

   ```
   cluster_src::> snapmirror update -source-path svm_backup:volA_dst
   -destination-path svm1:volA
   ```

   Learn more about `snapmirror update` in the ONTAP command reference.

4. From the original source SVM or the original source cluster, stop scheduled transfers for the reversed relationship:

   `snapmirror quiesce -source-path` *`SVM:volume`* `-destination-path` *`SVM:volume`*

   > You must run this command from the original source SVM or the original source cluster.

   The following example stops scheduled transfers between the original destination volume, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

   ```
   cluster_src::> snapmirror quiesce -source-path svm_backup:volA_dst
   -destination-path svm1:volA
   ```

   Learn more about `snapmirror quiesce` in the ONTAP command reference.

5. When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship::

   `snapmirror break -source-path` *`SVM:volume`* `-destination-path` *`SVM:volume`*

   > You must run this command from the original source SVM or the source cluster.

   The following example breaks the relationship between the original destination volume, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

```
cluster_scr::> snapmirror break -source-path svm_backup:volA_dst
-destination-path svm1:volA
```

Learn more about `snapmirror break` in the ONTAP command reference.

6. From the original source SVM or the original source cluster, delete the reversed data protection relationship:

   `snapmirror delete -source-path` *`SVM:volume`* `-destination-path` *`SVM:volume`*

   > You must run this command from the original source SVM or the original source cluster.

   The following example deletes the reversed relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

   ```
   cluster_src::> snapmirror delete -source-path svm_backup:volA_dst
   -destination-path svm1:volA
   ```

   Learn more about `snapmirror delete` in the ONTAP command reference.

7. Release the reversed relationship from the original destination SVM or the original destination cluster.

   `snapmirror release -source-path` *`SVM:volume`* `-destination-path` *`SVM:volume`*

   > You must run this command from the original destination SVM or the original destination cluster.

   The following example releases the reversed relationship between the original destination volume, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

   ```
   cluster_dst::> snapmirror release -source-path svm_backup:volA_dst
   -destination-path svm1:volA
   ```

   Learn more about `snapmirror release` in the ONTAP command reference.

8. Reestablish the original data protection relationship from the original destination:

   `snapmirror resync -source-path` *`SVM:volume`* `-destination-path` *`SVM:volume`*

   The following example reestablishes the relationship between the original source volume, `volA` on `svm1`, and the original destination volume, `volA_dst` on `svm_backup`:

   ```
   cluster_dst::> snapmirror resync -source-path svm1:volA -destination
   -path svm_backup:volA_dst
   ```

Learn more about `snapmirror resync` in the ONTAP command reference.

9. If needed, start the original destination SVM:

   `vserver start -vserver SVM`

   The following example starts the original destination SVM:

   ```
   cluster_dst::> vserver start svm_backup
   ```

   Learn more about `vserver start` in the ONTAP command reference.

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created.

Learn more about `snapmirror show` in the ONTAP command reference.

Restore files from a SnapMirror destination volume

Restore a file, LUN, or NVMe namespace from an ONTAP SnapMirror destination

You can restore a single file, LUN, a set of files or LUNs from a snapshot, or an NVMe namespace from a SnapMirror destination volume. Beginning with ONTAP 9.7, you can also restore NVMe namespaces from a SnapMirror synchronous destination. You can restore files to the original source volume or to a different volume.

Before you begin

To restore a file or LUN from a SnapMirror synchronous destination (supported beginning with ONTAP 9.5), you must first delete and release the relationship.

About this task

The volume to which you are restoring files or LUNs (the destination volume) must be a read-write volume:

- SnapMirror performs an *incremental restore* if the source and destination volumes have a common snapshot (as is typically the case when you are restoring to the original source volume).
- Otherwise, SnapMirror performs a *baseline restore*, in which the specified snapshot and all the data blocks it references are transferred to the destination volume.

Steps

1. List the snapshots in the destination volume:

   `volume snapshot show -vserver <SVM> -volume volume`

   Learn more about `volume snapshot show` in the ONTAP command reference.

   The following example shows the snapshots on the `vserverB:secondary1` destination:

```
cluster_dst::> volume snapshot show -vserver vserverB -volume secondary1

Vserver     Volume      Snapshot                State    Size  Total%
Used%
-------     ------      ---------- ----------- ------   -----  ------
-----
vserverB    secondary1  hourly.2013-01-25_0005  valid   224KB     0%
0%
                        daily.2013-01-25_0010   valid   92KB      0%
0%
                        hourly.2013-01-25_0105  valid   228KB     0%
0%
                        hourly.2013-01-25_0205  valid   236KB     0%
0%
                        hourly.2013-01-25_0305  valid   244KB     0%
0%
                        hourly.2013-01-25_0405  valid   244KB     0%
0%
                        hourly.2013-01-25_0505  valid   244KB     0%
0%

7 entries were displayed.
```

2. Restore a single file or LUN or a set of files or LUNs from a snapshot in a SnapMirror destination volume:

```
snapmirror restore -source-path <SVM:volume>|<cluster://SVM/volume>, …
-destination-path <SVM:volume>|<cluster://SVM/volume>, … -source-snapshot
snapshot -file-list <source_file_path,@destination_file_path>
```

You must run this command from the destination SVM or the destination cluster.

The following command restores the files `file1` and `file2` from the snapshot `daily.2013-01-25_0010` in the original destination volume `secondary1`, to the same location in the active file system of the original source volume `primary1`:

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-
25_0010 -file-list /dir1/file1,/dir2/file2

[Job 3479] Job is queued: snapmirror restore for the relationship with
destination vserverA:primary1
```

The following command restores the files `file1` and `file2` from the snapshot `daily.2013-01-25_0010` in the original destination volume `secondary1`, to a different location in the active file system of the original source volume `primary1`.

The destination file path begins with the @ symbol followed by the path of the file from the root of the original source volume. In this example, `file1` is restored to `/dir1/file1.new` and file2 is restored to `/dir2.new/file2` on `primary1`:

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-
25_0010 -file-list
/dir/file1,@/dir1/file1.new,/dir2/file2,@/dir2.new/file2

[Job 3479] Job is queued: snapmirror restore for the relationship with
destination vserverA:primary1
```

The following command restores the files `file1` and `file3` from the snapshot `daily.2013-01-25_0010` in the original destination volume `secondary1`, to different locations in the active file system of the original source volume `primary1`, and restores `file2` from `snap1` to the same location in the active file system of `primary1`.

In this example, the file `file1` is restored to `/dir1/file1.new` and `file3` is restored to `/dir3.new/file3`:

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-
25_0010 -file-list
/dir/file1,@/dir1/file1.new,/dir2/file2,/dir3/file3,@/dir3.new/file3

[Job 3479] Job is queued: snapmirror restore for the relationship with
destination vserverA:primary1
```

Related information

- snapmirror restore

Restore volume contents from an ONTAP SnapMirror destination

You can restore the contents of an entire volume from a snapshot in a SnapMirror destination volume. You can restore the volume’s contents to the original source volume or to a different volume.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to restore data. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

The destination volume for the restore operation must be one of the following:

- A read-write volume, in which case SnapMirror performs an *incremental restore*, provided that the source and destination volumes have a common snapshot (as is typically the case when you are restoring to the original source volume).

> ⓘ The command fails if there is not a common snapshot. You cannot restore the contents of a volume to an empty read-write volume.

* An empty data protection volume, in which case SnapMirror performs a *baseline restore*, in which the specified snapshot and all the data blocks it references are transferred to the source volume.

Restoring the contents of a volume is a disruptive operation. SMB traffic must not be running on the SnapVault primary volume when a restore operation is running.

If the destination volume for the restore operation has compression enabled, and the source volume does not have compression enabled, disable compression on the destination volume. You need to re-enable compression after the restore operation is complete.

Any quota rules defined for the destination volume are deactivated before the restore is performed. You can use the `volume quota modify` command to reactivate quota rules after the restore operation is complete.

When data in a volume is lost or corrupted, you can roll back your data by restoring from an earlier snapshot.

This procedure replaces the current data on the source volume with data from an earlier snapshot version. You should perform this task on the destination cluster.

Steps

You can restore a volume's contents using System Manager or the ONTAP CLI.

System Manager

1. Click **Protection > Relationships**, and then click the source volume name.
2. Click ⋮ and then select **Restore**.
3. Under **Source**, the source volume is selected by default. Click **Other Volume** if you want to choose a volume other than the source.
4. Under **Destination**, choose the snapshot you want to restore.
5. If your source and destination are located on different clusters, on the remote cluster, click **Protection > Relationships** to monitor the restore progress.

CLI

1. List the snapshots in the destination volume:

```
volume snapshot show -vserver <SVM> -volume <volume>
```

The following example shows the snapshots on the `vserverB:secondary1` destination:

```
cluster_dst::> volume snapshot show -vserver vserverB -volume
secondary1

Vserver     Volume      Snapshot                State    Size
Total% Used%
-------     ------      ---------- ----------- ------   -----
------ -----
vserverB    secondary1  hourly.2013-01-25_0005  valid   224KB     0%
0%
                        daily.2013-01-25_0010   valid   92KB      0%
0%
                        hourly.2013-01-25_0105  valid   228KB     0%
0%
                        hourly.2013-01-25_0205  valid   236KB     0%
0%
                        hourly.2013-01-25_0305  valid   244KB     0%
0%
                        hourly.2013-01-25_0405  valid   244KB     0%
0%
                        hourly.2013-01-25_0505  valid   244KB     0%
0%

7 entries were displayed.
```

2. Restore the contents of a volume from a snapshot in a SnapMirror destination volume:

```
snapmirror restore -source-path <SVM:volume>|<cluster://SVM/volume>
-destination-path <SVM:volume>|<cluster://SVM/volume> -source-snapshot
```

```
<snapshot>
```

ⓘ You must run this command from the original source SVM or the original source cluster.

The following command restores the contents of the original source volume `primary1` from the snapshot `daily.2013-01-25_0010` in the original destination volume `secondary1`:

```
cluster_src::> snapmirror restore -source-path vserverB:secondary1
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-
25_0010

Warning: All data newer than snapshot daily.2013-01-25_0010 on
volume vserverA:primary1 will be deleted.

Do you want to continue? {y|n}: y

[Job 34] Job is queued: snapmirror restore from source
vserverB:secondary1 for the snapshot daily.2013-01-25_0010.
```

3. Remount the restored volume and restart all applications that use the volume.

Other ways to do this in ONTAP

To perform these tasks with…	See this content…
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume restore using SnapVault overview

Related information

- snapmirror restore
- volume snapshot show

Update an ONTAP SnapMirror replication relationship manually

You might need to update a replication relationship manually if an update fails because the source volume has been moved.

About this task

SnapMirror aborts any transfers from a moved source volume until you update the replication relationship manually.

Beginning with ONTAP 9.5, SnapMirror synchronous relationships are supported. Although the source and destination volumes are in sync at all times in these relationships, the view from the secondary cluster is synchronized with the primary only on an hourly basis. If you want to view the point-in-time data at the destination, you should perform a manual update by running the `snapmirror update` command.

Step

1. Update a replication relationship manually:

   ```
   snapmirror update -source-path <SVM:volume>|<cluster://SVM/volume>, …
   -destination-path <SVM:volume>|<cluster://SVM/volume>, …
   ```

   > You must run this command from the destination SVM or the destination cluster. The command fails if a common snapshot does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship. Learn more about `snapmirror initialize` in the ONTAP command reference.

   The following example updates the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

   ```
   cluster_src::> snapmirror update -source-path svm1:volA -destination
   -path svm_backup:volA_dst
   ```

   Learn more about `snapmirror update` in the ONTAP command reference.

Resynchronize an ONTAP SnapMirror replication relationship

You need to resynchronize a replication relationship after you make a destination volume writeable, after an update fails because a common snapshot does not exist on the source and destination volumes, or if you want to change the replication policy for the relationship.

Beginning with ONTAP 9.8, you can use System Manager to perform a reverse resynchronization operation to delete an existing protection relationship and reverse the functions of the source and destination volumes. Then you use the destination volume to serve data while you repair or replace the source, update the source, and reestablish the original configuration of the systems.

About this task

- Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.
- Volumes that are part of a fan-out or cascade configuration can take longer to resynchronize. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

> System Manager does not support reverse resynchronization with intracluster relationships. You can use the ONTAP CLI to perform reverse resync operations with intracluster relationships.

Steps

You can use System Manager or the ONTAP CLI to perform this task. If you use the ONTAP CLI, the procedure is the same regardless of whether you are making a destination volume writable or you are updating the replication relationship.

System Manager reverse resync

After you break a relationship to make a destination writable, reverse resynchronize the relationship:

1. On the destination cluster, click **Protection > Relationships**.
2. Hover over the broken off relationship you want to reverse, click ⋮, and select **Reverse Resync**.
3. In the **Reverse resync relationship** window, click **Reverse resync**.
4. Under **Relationships**, monitor the reverse resynchronization progress by viewing **Transfer Status** for the relationship.

Next steps

When the original source is available again, you can reestablish the original relationship by breaking the reversed relationship and performing another reverse resync operation. The reverse resync process will copy any changes from the site that is serving data to the original source and make the original source read-writable again.

System Manager resync

1. Click **Protection > Relationships**.
2. Hover over the relationship you want to resynchronize, and click ⋮ and then select **Break**.
3. When the relationship state displays "Broken off," click ⋮ and then select **Resync**.
4. Under **Relationships**, monitor the resynchronization progress by checking the relationship state. The state changes to "Mirrored" when resynchronization is complete.

CLI

1. Resync the source and destination volumes:

```
snapmirror resync -source-path <SVM:volume|cluster://SVM/volume>
-destination-path <SVM:volume|cluster://SVM/volume> -type DP|XDP
-policy <policy>
```

You must run this command from the destination SVM or the destination cluster.

The following example resynchronizes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

Learn more about `snapmirror resync` in the ONTAP command reference.

Delete an ONTAP SnapMirror volume replication relationship

You can use the `snapmirror delete` and `snapmirror release` commands to delete a volume replication relationship. You can then delete unneeded destination volumes manually.

About this task

The `snapmirror release` command deletes any SnapMirror-created snapshots from the source. You can use the `-relationship-info-only` option to preserve the snapshots.

Steps

1. Quiesce the replication relationship:

   `snapmirror quiesce -destination-path <SVM:volume>|<cluster://SVM/volume>`

   ```
   cluster_dst::> snapmirror quiesce -destination-path svm_backup:volA_dst
   ```

   Learn more about `snapmirror quiesce` in the ONTAP command reference.

2. (Optional) Break the replication relationship if you require the destination volume to be a read/write volume. You can skip this step if you plan to delete the destination volume or if you don't need the volume to be read/write:

   `snapmirror break -source-path <SVM:volume>|<cluster://SVM/volume>, … -destination-path <SVM:volume>|<cluster://SVM/volume>, …`

   ```
   cluster_dst::> snapmirror break -source-path svm1:volA -destination-path
   svm_backup:volA_dst
   ```

   Learn more about `snapmirror break` in the ONTAP command reference.

3. Delete the replication relationship:

   `snapmirror delete -source-path <SVM:volume>|<cluster://SVM/volume>, … -destination-path <SVM:volume>|<cluster://SVM/volume>, …`

   > You must run this command from the destination cluster or destination SVM.

   The following example deletes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

   ```
   cluster_dst::> snapmirror delete -source-path svm1:volA -destination
   -path svm_backup:volA_dst
   ```

   Learn more about `snapmirror delete` in the ONTAP command reference.

4. Release replication relationship information from the source SVM:

   `snapmirror release -source-path <SVM:volume>|<cluster://SVM/volume>, … -destination-path <SVM:volume>|<cluster://SVM/volume>, …`

ⓘ You must run this command from the source cluster or source SVM.

The following example releases information for the specified replication relationship from the source SVM `svm1`:

```
cluster_src::> snapmirror release -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

Learn more about `snapmirror release` in the ONTAP command reference.

Manage storage efficiency on ONTAP SnapMirror volumes

SnapMirror preserves storage efficiency on the source and destination volumes except when postprocess data compression is enabled on the destination volume. In that case, all storage efficiency is lost on the destination volume. To correct this issue, you need to disable postprocess compression on the destination volume, update the relationship manually, and re-enable storage efficiency.

About this task

You can use the `volume efficiency show` command to determine whether efficiency is enabled on a volume.
Learn more about `volume efficiency show` in the ONTAP command reference.

You can check if SnapMirror is maintaining storage efficiency by viewing the SnapMirror audit logs and locating the transfer description. If the transfer description displays `transfer_desc=Logical Transfer with Storage Efficiency`, SnapMirror is maintaining storage efficiency. If the transfer description displays `transfer_desc=Logical Transfer`, SnapMirror is not maintaining storage efficiency. For example:

```
Fri May 22 02:13:02 CDT 2020 ScheduledUpdate[May 22 02:12:00]:cc0fbc29-
b665-11e5-a626-00a09860c273 Operation-Uuid=39fbcf48-550a-4282-a906-
df35632c73a1 Group=none Operation-Cookie=0 action=End source=<sourcepath>
destination=<destpath> status=Success bytes_transferred=117080571
network_compression_ratio=1.0:1 transfer_desc=Logical Transfer - Optimized
Directory Mode
```

Before you begin

- The source and destination clusters and SVMs must be peered.

  Cluster and SVM peering

- You must disable postprocess compression on the destination volume.
- Logical Transfer with storage: Beginning with ONTAP 9.3, manual update is no longer required to re-enable storage efficiency. If SnapMirror detects that postprocess compression has been disabled, it automatically re-enables storage efficiency at the next scheduled update. Both the source and the destination must be running ONTAP 9.3.
- Beginning with ONTAP 9.3, AFF systems manage storage efficiency settings differently from FAS systems

after a destination volume is made writeable:

- After you make a destination volume writeable using the `snapmirror break` command, the caching policy on the volume is automatically set to `auto` (the default).

  > This behavior is applicable to FlexVol volumes, only, and it does not apply to FlexGroup volumes.

  Learn more about `snapmirror break` in the ONTAP command reference.

- On resync, the caching policy is automatically set to `none`, and deduplication and inline compression are automatically disabled, regardless of your original settings. You must modify the settings manually as needed.

> Manual updates with storage efficiency enabled can be time-consuming. You might want to run the operation in off-peak hours.

Steps

1. Update a replication relationship and re-enable storage efficiency:

```
snapmirror update -source-path <SVM:volume>|<cluster://SVM/volume>, ...
-destination-path <SVM:volume>|<cluster://SVM/volume>, ... -enable
-storage-efficiency true
```

> You must run this command from the destination SVM or the destination cluster. The command fails if a common snapshot does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship. Learn more about `snapmirror initialize` in the ONTAP command reference.

The following example updates the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`, and re-enables storage efficiency:

```
cluster_dst::> snapmirror update -source-path svm1:volA -destination
-path svm_backup:volA_dst -enable-storage-efficiency true
```

Learn more about `snapmirror update` in the ONTAP command reference.

Use ONTAP SnapMirror global throttling

Global network throttling is available for all SnapMirror and SnapVault transfers at a per-node level.

About this task

SnapMirror global throttling restricts the bandwidth used by incoming and/or outgoing SnapMirror and SnapVault transfers. The restriction is enforced cluster wide on all nodes in the cluster.

For example, if the outgoing throttle is set to 100 MBps, each node in the cluster will have the outgoing bandwidth set to 100 MBps. If global throttling is disabled, it is disabled on all nodes.

Although data transfer rates are often expressed in bits per second (bps), the throttle values must be entered in kilobytes per second (KBps).

> In ONTAP 9.9.1 and earlier releases, the throttle has no effect on `volume move` transfers or load-sharing mirror transfers. Beginning with ONTAP 9.10.0, you can specify an option to throttle a volume move operation. For details, see How to throttle volume move in ONTAP 9.10 and later.

Global throttling works with the per-relationship throttle feature for SnapMirror and SnapVault transfers. The per-relationship throttle is enforced until the combined bandwidth of per-relationship transfers exceeds the value of the global throttle, after which the global throttle is enforced. A throttle value `0` implies that global throttling is disabled.

> SnapMirror global throttling has no effect on SnapMirror synchronous relationships when they are In-Sync. However, the throttle does effect SnapMirror synchronous relationships when they perform an asynchronous transfer phase such as an initialization operation or after an Out Of Sync event. For this reason, enabling global throttling with SnapMirror synchronous relationships is not recommended.

Steps

1. Enable global throttling:

   `options -option-name replication.throttle.enable on|off`

   The following example shows how to enable SnapMirror global throttling on `cluster_dst`:

   ```
   cluster_dst::> options -option-name replication.throttle.enable on
   ```

2. Specify the maximum total bandwidth used by incoming transfers on the destination cluster:

   `options -option-name replication.throttle.incoming.max_kbs <KBps>`

   The recommended minimum throttle bandwidth is 4 kilobytes per second (KBps) and the maximum is up to 2 terabytes per second (TBps). The default value for this option is `unlimited`, which means there is no limit on total bandwidth used.

   The following example shows how to set the maximum total bandwidth used by incoming transfers to 100 megabits per second (Mbps):

   ```
   cluster_dst::> options -option-name
   replication.throttle.incoming.max_kbs 12500
   ```

   > 100 megabits per second (Mbps) = 12500 kilobytes per second (KBps)

3. Specify the maximum total bandwidth used by outgoing transfers on the source cluster:

   `options -option-name replication.throttle.outgoing.max_kbs <KBps>`

The recommended minimum throttle bandwidth is 4 KBps and the maximum is up to 2 TBps. The default value for this option is `unlimited`, which means there is no limit on total bandwidth used. Parameter values are in kilobytes per second (KBps).

The following example shows how to set the maximum total bandwidth used by outgoing transfers to 100 Mbps:

```
cluster_src::> options -option-name
replication.throttle.outgoing.max_kbs 12500
```

Manage SnapMirror SVM replication

Learn about ONTAP SnapMirror SVM replication

You can use SnapMirror to create a data protection relationship between SVMs. In this type of data protection relationship, all or part of the SVM’s configuration, from NFS exports and SMB shares to RBAC, is replicated, as well as the data in the volumes that the SVM owns.

Supported relationship types

Only data-serving SVMs can be replicated. The following data protection relationship types are supported:

- *SnapMirror DR,* in which the destination typically contains only the snapshots currently on the source.

  Beginning with ONTAP 9.9.1, this behavior changes when you are using the mirror-vault policy. Beginning with ONTAP 9.9.1, you can create different snapshot policies on the source and destination, and the snapshots on the destination are not overwritten by snapshots on the source:

  - They are not overwritten from the source to the destination during normal scheduled operations, updates and resync
  - They are not deleted during break operations.
  - They are not deleted during flip-resync operations.
    When you configure an SVM disaster relationship using the mirror-vault policy using ONTAP 9.9.1 and later, the policy behaves as follows:
  - User-defined snapshot policies at the source are not copied to the destination.
  - System-defined snapshot policies are not copied to the destination.
  - Volume association with user and system defined snapshot policies are not copied to the destination.

    SVM.
- *SnapMirror unified replication,* in which the destination is configured for both DR and long-term retention.

For more information about SnapMirror unified replication, see SnapMirror unified replication basics.

The *policy type* of the replication policy determines the type of relationship it supports. The following table shows the available policy types.

Policy type	Relationship type
async-mirror	SnapMirror DR
mirror-vault	Unified replication

XDP replaces DP as the SVM replication default in ONTAP 9.4

Beginning with ONTAP 9.4, SVM data protection relationships default to XDP mode. SVM data protection relationships continue to default to DP mode in ONTAP 9.3 and earlier.

Existing relationships are not affected by the XDP default. If a relationship is already of type DP, it will continue to be of type DP. The following table shows the behavior you can expect.

If you specify…	The type is…	The default policy (if you do not specify a policy) is…
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAllSnapshots (SnapMirror DR)
XDP	XDP	MirrorAndVault (Unified replication)

You can find information about converting DP relationships to XDP relationships and other details here: Convert an existing ONTAP DP-type relationship to XDP.

> Version-independence is not supported for SVM replication. In an SVM disaster recovery configuration, the destination SVM must be on a cluster running the same ONTAP version as the source SVM cluster to support failover and fail back operations.

Compatible ONTAP versions for SnapMirror relationships

How SVM configurations are replicated

The content of an SVM replication relationship is determined by the interaction of the following fields:

- The `-identity-preserve true` option of the `snapmirror create` command replicates the entire SVM configuration.

  The `-identity-preserve false` option replicates only the volumes and authentication and authorization configurations of the SVM, and the protocol and name service settings listed in Configurations replicated in SVM disaster recovery relationships.

- The `-discard-configs network` option of the `snapmirror policy create` command excludes LIFs and related network settings from SVM replication, for use in cases where the source and destination SVMs are in different subnets.
- The `-vserver-dr-protection unprotected` option of the `volume modify` command excludes the specified volume from SVM replication.

Otherwise, SVM replication is almost identical to volume replication. You can use virtually the same workflow for SVM replication as you use for volume replication.

Support details

The following table shows support details for SnapMirror SVM replication.

Resource or feature	Support details
Deployment types	• Single source to single destination • Beginning with ONTAP 9.4, fan-out. You can fan-out to two destinations only. By default, only one -identity-preserve true relationship is allowed per source SVM.
Relationship types	• SnapMirror disaster recovery • SnapMirror unified replication
Replication scope	Intercluster only. You cannot replicate SVMs in the same cluster.
Autonomous Ransomware Protection	• Supported beginning with ONTAP 9.12.1. For more information, see Autonomous Ransomware Protection.
Consistency groups asynchronous support	Beginning with ONTAP 9.14.1, a maximum of 32 SVM disaster recovery relationships are supported when consistency groups exist. See Protect a consistency group and Consistency group limits for more information.
FabricPool	Beginning with ONTAP 9.6, SnapMirror SVM replication is supported with FabricPool. When in an SVM DR relationship, source and destination volumes do not need to use FabricPool aggregates, but they must use the same tiering policy. Beginning with ONTAP 9.12.1, SnapMirror SVM replication is supported with FabricPool and FlexGroup volumes working in conjunction. Prior to 9.12.1, any two of these features worked together, but not all three together.

MetroCluster	Beginning with ONTAP 9.11.1, both sides of a SVM disaster recovery relationship within a MetroCluster configuration can act as a source for additional SVM disaster recovery configurations. Beginning with ONTAP 9.5, SnapMirror SVM replication is supported on MetroCluster configurations. • In releases earlier than ONTAP 9.10.X, a MetroCluster configuration cannot be the destination of an SVM disaster recovery relationship. • In ONTAP 9.10.1 and later releases, a MetroCluster configuration can be the destination of an SVM disaster recovery relationship for migration purposes only, and it must meet all necessary requirements described in TR-4966: Migrating a SVM into a MetroCluster solution. • Only an active SVM within a MetroCluster configuration can be the source of an SVM disaster recovery relationship. A source can be a sync-source SVM before switchover or a sync-destination SVM after switchover. • When a MetroCluster configuration is in a steady state, the MetroCluster sync-destination SVM cannot be the source of an SVM disaster recovery relationship, since the volumes are not online. • When the sync-source SVM is the source of an SVM disaster recovery relationship, the source SVM disaster recovery relationship information is replicated to the MetroCluster partner. • During the switchover and switchback processes, replication to the SVM disaster recovery destination might fail. However, after the switchover or switchback process completes, the next SVM disaster recovery scheduled updates will succeed.
Consistency group	Supported beginning with ONTAP 9.14.1. For more information, see Protect a consistency group.
ONTAP S3	Not supported with SVM disaster recovery.
SnapMirror Synchronous	Not supported with SVM disaster recovery.

Version-independence	Not supported.
Volume encryption	• Encrypted volumes on the source are encrypted on the destination. • Onboard Key Manager or KMIP servers must be configured on the destination. • New encryption keys are generated at the destination. • If the destination does not contain a node that supports volume .encryption, replication succeeds, but the destination volumes are not encrypted.

Configurations replicated in SVM disaster recovery relationships

The following table shows the interaction of the `snapmirror create -identity-preserve` option and the `snapmirror policy create -discard-configs network` option:

Configuration replicated		**`-identity-preserve true`**		**`-identity-preserve false`**
		Policy without `-discard -configs network` set	**Policy with `-discard -configs network` set**	
Network	NAS LIFs	Yes	No	No

SVM disaster recovery storage limits

The following table shows the recommended maximum number of volumes and SVM disaster recovery relationships supported per storage object. You should be aware that limits are often platform dependent. Refer to the Hardware Universe to learn the limits for your specific configuration.

Storage object	Limit
SVM	300 Flexible volumes
HA pair	1,000 Flexible Volumes
Cluster	128 SVM disaster relationships

Related information

- snapmirror create
- snapmirror policy create

Replicate SVM configurations

ONTAP SnapMirror SVM replication workflow

SnapMirror SVM replication involves creating the destination SVM, creating a replication job schedule, and creating and initializing a SnapMirror relationship.

You should determine which replication workflow best suits your needs:

- Replicate an entire SVM configuration
- Exclude LIFs and related network settings from SVM replication
- Exlude network, name service, and other settings from SVM configuration

Criteria for placing volumes on ONTAP SnapMirror destination SVMs

When replicating volumes from the source SVM to the destination SVM, it’s important to know the criteria for selecting aggregates.

Aggregates are selected based on the following criteria:

- Volumes are always placed on non-root aggregates.
- Non-root aggregates are selected based on the available free space and the number of volumes already hosted on the aggregate.

  Aggregates with more free space and fewer volumes are given priority. The aggregate with the highest priority is selected.
- Source volumes on FabricPool aggregates are placed on FabricPool aggregates on the destination with the same tiering-policy.
- If a volume on the source SVM is located on a Flash Pool aggregate, then the volume is placed on a Flash Pool aggregate on the destination SVM, if such an aggregate exists and has enough free space.
- If the `-space-guarantee` option of the volume that is replicated is set to `volume`, only aggregates with free space greater than the volume size are considered.
- The volume size grows automatically on the destination SVM during replication, based on the source volume size.

  If you want to pre-reserve the size on the destination SVM, you must resize the volume. The volume size does not shrink automatically on the destination SVM based on the source SVM.

If you want to move a volume from one aggregate to another, you can use the `volume move` command on the destination SVM.

Replicate an entire ONTAP SVM configuration

You can create an SVM disaster recovery (SVM DR) relationship to replicate one SVM configuration to another. In the event of a disaster at the primary site, you can quickly activate the destination SVM.

Before you begin

The source and destination clusters and SVMs must be peered.
For more information, see Create a cluster peer relationship and Create an SVM intercluster peer relationship.

Learn more about the commands described in this procedure in the ONTAP command reference.

About this task

This workflow assumes that you are already using a default policy or a custom replication policy.

Beginning with ONTAP 9.9.1, when you use the mirror-vault policy, you can create different snapshot policies on the source and destination SVM, and the snapshots on the destination are not overwritten by snapshots on the source. For more information, see Understanding SnapMirror SVM replication.

Complete this procedure from the destination. If you need to create a new protection policy, for instance, when your source storage VM has SMB configured, you should create the policy and use the **Identity preserve** option.
For details see Create custom data protection policies.

Steps

You can perform this task from System Manager or the ONTAP CLI.

System Manager

1. On the destination cluster, click **Protection > Relationships**.
2. Under **Relationships**, click **Protect** and choose **Storage VMs (DR)**.
3. Select a protection policy. If you created a custom protection policy, select it, then choose the source cluster and storage VM you want to replicate. You can also create a new destination storage VM by entering a new storage VM name.
4. If desired, change the destination settings to override identity preserve and to include or exclude network interfaces and protocols.
5. Click **Save**.

CLI

1. Create a destination SVM:

   ```
   vserver create -vserver <SVM_name> -subtype dp-destination
   ```

   The SVM name must be unique across the source and destination clusters.

   The following example creates a destination SVM named `svm_backup`:

   ```
   cluster_dst:> vserver create -vserver svm_backup -subtype dp-
   destination
   ```

   Learn more about `vserver create` in the ONTAP command reference.

2. From the destination cluster, create an SVM peer relationship using the `vserver peer create` command.

   For more information, see Create an SVM intercluster peer relationship.

   Learn more about `vserver peer create` in the ONTAP command reference.

3. Create a replication job schedule:

   ```
   job schedule cron create -name <job_name> -month <month> -dayofweek
   <day_of_week> -day <day_of_month> -hour <hour> -minute <minute>
   ```

   For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

   > The minimum supported schedule (RPO) for FlexVol volumes in an SVM SnapMirror relationship is 15 minutes. The minimum supported schedule (RPO) for FlexGroup volumes in an SVM SnapMirror relationship is 30 minutes.

   The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek
saturday -hour 3 -minute 0
```

Learn more about `job schedule cron create` in the ONTAP command reference.

4. From the destination SVM or the destination cluster, create a replication relationship:

```
snapmirror create -source-path <SVM_name>: -destination-path
<SVM_name>: -type <DP|XDP> -schedule <schedule> -policy <policy>
-identity-preserve true
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options.

The following example creates a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror create -source-path svm1: -destination
-path svm_backup: -type XDP -schedule my_daily -policy
MirrorAllSnapshots -identity-preserve true
```

The following example creates a unified replication relationship using the default `MirrorAndVault` policy:

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy MirrorAndVault
-identity-preserve true
```

Assuming you have created a custom policy with the policy type `async-mirror`, the following example creates a SnapMirror DR relationship:

```
cluster_dst::> snapmirror create -source-path svm1: -destination
-path svm_backup: -type XDP -schedule my_daily -policy my_mirrored
-identity-preserve true
```

Assuming you have created a custom policy with the policy type `mirror-vault`, the following example creates a unified replication relationship:

```
cluster_dst::> snapmirror create -source-path svm1: -destination
-path svm_backup: -type XDP -schedule my_daily -policy my_unified
-identity-preserve true
```

Learn more about `snapmirror create` in the ONTAP command reference.

5. Stop the destination SVM:

```
vserver stop -vserver <SVM_name>
```

The following example stops a destination SVM named svm_backup:

```
cluster_dst::> vserver stop -vserver svm_backup
```

Learn more about `vserver stop` in the ONTAP command reference.

6. From the destination SVM or the destination cluster, initialize the SVM replication relationship:

```
snapmirror initialize -source-path <SVM_name>: -destination-path
<SVM_name>:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options.

The following example initializes the relationship between the source SVM, `svm1`, and the destination SVM, `svm_backup`:

```
cluster_dst::> snapmirror initialize -source-path svm1: -destination
-path svm_backup:
```

Learn more about `snapmirror initialize` in the ONTAP command reference.

Exclude LIFs and related network settings from ONTAP SnapMirror SVM replication

If the source and destination SVMs are in different subnets, you can use the `-discard -configs network` option of the `snapmirror policy create` command to exclude LIFs and related network settings from SVM replication.

Before you begin

The source and destination clusters and SVMs must be peered.

For more information, see Create a cluster peer relationship and Create an SVM intercluster peer relationship.

About this task

The `-identity-preserve` option of the `snapmirror create` command must be set to `true` when you create the SVM replication relationship.

Steps

1. Create a destination SVM:

   `vserver create -vserver SVM -subtype dp-destination`

   The SVM name must be unique across the source and destination clusters.

   The following example creates a destination SVM named `svm_backup`:

   ```
   cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
   ```

2. From the destination cluster, create an SVM peer relationship using the `vserver peer create` command.

   For more information, see Create an SVM intercluster peer relationship.

   Learn more about `vserver peer create` in the ONTAP command reference.

3. Create a job schedule:

   `job schedule cron create -name job_name -month month -dayofweek day_of_week -day day_of_month -hour hour -minute minute`

   For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

   > The minimum supported schedule (RPO) for FlexVol volumes in an SVM SnapMirror relationship is 15 minutes. The minimum supported schedule (RPO) for FlexGroup volumes in an SVM SnapMirror relationship is 30 minutes.

   The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

   ```
   cluster_dst::> job schedule cron create -name my_weekly -dayofweek
   "Saturday" -hour 3 -minute 0
   ```

4. Create a custom replication policy:

   `snapmirror policy create -vserver SVM -policy policy -type async-mirror|vault|mirror-vault -comment comment -tries transfer_tries -transfer -priority low|normal -is-network-compression-enabled true|false -discard -configs network`

   The following example creates a custom replication policy for SnapMirror DR that excludes LIFs:

   ```
   cluster_dst::> snapmirror policy create -vserver svm1 -policy
   DR_exclude_LIFs -type async-mirror -discard-configs network
   ```

   The following example creates a custom replication policy for unified replication that excludes LIFs:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy
unified_exclude_LIFs -type mirror-vault -discard-configs network
```

Consider creating the same custom SnapMirror policy on the source cluster for future failover and failback scenarios.

Learn more about `snapmirror policy create` in the ONTAP command reference.

5. From the destination SVM or the destination cluster, run the following command to create a replication relationship:

   `snapmirror create -source-path` *`SVM`*`: -destination-path` *`SVM`*`: -type DP|XDP -schedule` *`schedule`* `-policy` *`policy`* `-identity-preserve true|false -discard -configs true|false`

   You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the examples below.

   The following example creates a SnapMirror DR relationship that excludes LIFs:

   ```
   cluster_dst::> snapmirror create -source-path svm1: -destination-path
   svm_backup: -type XDP -schedule my_weekly -policy DR_exclude_LIFs
   -identity-preserve true
   ```

   The following example creates a SnapMirror unified replication relationship that excludes LIFs:

   ```
   cluster_dst::> snapmirror create -source-path svm1: -destination-path
   svm_backup: -type XDP -schedule my_weekly -policy unified_exclude_LIFs
   -identity-preserve true -discard-configs true
   ```

   Learn more about `snapmirror create` in the ONTAP command reference.

6. Stop the destination SVM:

   `vserver stop`

   `SVM name`

   The following example stops the destination SVM named svm_backup:

   ```
   cluster_dst::> vserver stop -vserver svm_backup
   ```

7. From the destination SVM or the destination cluster, initialize a replication relationship:

   `snapmirror initialize -source-path` *`SVM`*`: -destination-path` *`SVM`*`:`

The following example initializes the relationship between the source, `svm1` and the destination, `svm_backup`:

```
cluster_dst::> snapmirror initialize -source-path svm1: -destination
-path svm_backup:
```

Learn more about `snapmirror initialize` in the ONTAP command reference.

After you finish

You must configure the network and protocols on the destination SVM for data access in the event a disaster occurs.

Related information

- snapmirror create
- snapmirror initialize
- snapmirror policy create

Exclude network, name service, and other settings from SVM replication with ONTAP

You might want to exclude network, name service, and other settings from an SVM replication relationship to avoid conflicts or configuration differences with the destination SVM.

You can use the `-identity-preserve false` option of the `snapmirror create` command to replicate only the volumes and security configurations of an SVM. Some protocol and name service settings are also preserved.

About this task

For a list of preserved protocol and name service settings, see Configurations replicated in SVM DR relationships.

Before you begin

The source and destination clusters and SVMs must be peered.

For more information, see Create a cluster peer relationship and Create an SVM intercluster peer relationship.

Steps

1. Create a destination SVM:

   `vserver create -vserver SVM -subtype dp-destination`

   The SVM name must be unique across the source and destination clusters.

   The following example creates a destination SVM named `svm_backup`:

   ```
   cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
   ```

2. From the destination cluster, create an SVM peer relationship using the `vserver peer create` command.

   For more information, see Create an SVM intercluster peer relationship.

   Learn more about `vserver peer create` in the ONTAP command reference.

3. Create a replication job schedule:

   `job schedule cron create -name *job_name* -month *month* -dayofweek *day_of_week* -day *day_of_month* -hour *hour* -minute *minute*`

   For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

   > The minimum supported schedule (RPO) for FlexVol volumes in an SVM SnapMirror relationship is 15 minutes. The minimum supported schedule (RPO) for FlexGroup volumes in an SVM SnapMirror relationship is 30 minutes.

   The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

   ```
   cluster_dst::> job schedule cron create -name my_weekly -dayofweek
   "Saturday" -hour 3 -minute 0
   ```

4. Create a replication relationship that excludes network, name service, and other configuration settings:

   `snapmirror create -source-path *SVM*: -destination-path *SVM*: -type DP|XDP -schedule schedule -policy policy -identity-preserve false`

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the examples below. You must run this command from the destination SVM or the destination cluster.

   The following example creates a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy. The relationship excludes network, name service, and other configuration settings from SVM replication:

   ```
   cluster_dst::> snapmirror create -source-path svm1: -destination-path
   svm_backup: -type XDP -schedule my_daily -policy MirrorAllSnapshots
   -identity-preserve false
   ```

   The following example creates a unified replication relationship using the default `MirrorAndVault` policy. The relationship excludes network, name service, and other configuration settings:

```
cluster_dst:> snapmirror create svm1: -destination-path svm_backup:
-type XDP -schedule my_daily -policy MirrorAndVault -identity-preserve
false
```

Assuming you have created a custom policy with the policy type `async-mirror`, the following example creates a SnapMirror DR relationship. The relationship excludes network, name service, and other configuration settings from SVM replication:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy my_mirrored -identity
-preserve false
```

Assuming you have created a custom policy with the policy type `mirror-vault`, the following example creates a unified replication relationship. The relationship excludes network, name service, and other configuration settings from SVM replication:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy my_unified -identity
-preserve false
```

Learn more about `snapmirror create` in the ONTAP command reference.

5. Stop the destination SVM:

   `vserver stop`

   `SVM name`

   The following example stops a destination SVM named dvs1:

   ```
   destination_cluster::> vserver stop -vserver dvs1
   ```

6. If you are using SMB, you must also configure an SMB server.

   See SMB only: Creating an SMB server.

7. From the destination SVM or the destination cluster, initialize the SVM replication relationship:

   `snapmirror initialize -source-path` *`SVM_name`*`: -destination-path` *`SVM_name`*`:`

   Learn more about `snapmirror initialize` in the ONTAP command reference.

After you finish

You must configure the network and protocols on the destination SVM for data access in the event a disaster occurs.

Specify local tiers to use for ONTAP SnapMirror SVM DR relationships

After a disaster recovery SVM is created, you can use the `aggr-list` option with `vserver modify` command to limit which local tiers are used to host SVM DR destination volumes.

Steps

1. Create a destination SVM:

   ```
   vserver create -vserver SVM -subtype dp-destination
   ```

2. Modify the disaster recovery SVM's aggr-list to limit the local tiers that are used to host the disaster recovery SVM's volume:

   ```
   cluster_dest::> vserver modify -vserver SVM -aggr-list <comma-separated-list>
   ```

Create an SMB server for an ONTAP SnapMirror destination SVM in a DR relationship

If the source SVM has an SMB configuration, and you chose to set `identity-preserve` to `false`, you must create an SMB server for the destination SVM. An SMB server is required for some SMB configurations, such as shares during initialization of the SnapMirror relationship.

Steps

1. Start the destination SVM by using the `vserver start` command.

   ```
   destination_cluster::> vserver start -vserver dvs1
   [Job 30] Job succeeded: DONE
   ```

   Learn more about `vserver start` in the ONTAP command reference.

2. Verify that the destination SVM is in the `running` state and subtype is `dp-destination` by using the `vserver show` command.

   ```
   destination_cluster::> vserver show
                                             Admin      Operational  Root
   Vserver   Type     Subtype              State      State        Volume
   Aggregate
   -------- ------- ----------         ---------- ----------- ----------
   ----------
   dvs1     data    dp-destination     running    running        -         -
   ```

   Learn more about `vserver show` in the ONTAP command reference.

3. Create a LIF by using the `network interface create` command.

```
destination_cluster::>network interface create -vserver dvs1 -lif NAS1
-role data -data-protocol cifs -home-node destination_cluster-01 -home
-port a0a-101  -address 192.0.2.128 -netmask 255.255.255.128
```

Learn more about `network interface create` in the ONTAP command reference.

4. Create a route by using the `network route create` command.

```
destination_cluster::>network route create -vserver dvs1 -destination
0.0.0.0/0
-gateway 192.0.2.1
```

Network management

Learn more about `network route create` in the ONTAP command reference.

5. Configure DNS by using the `vserver services dns create` command.

```
destination_cluster::>vserver services dns create -domains
mydomain.example.com -vserver
dvs1 -name-servers 192.0.2.128 -state enabled
```

Learn more about `vserver services dns create` in the ONTAP command reference.

6. Add the preferred domain controller by using the `vserver cifs domain preferred-dc add` command.

```
destination_cluster::>vserver cifs domain preferred-dc add -vserver dvs1
-preferred-dc
192.0.2.128 -domain mydomain.example.com
```

Learn more about `vserver cifs domain preferred-dc add` in the ONTAP command reference.

7. Create the SMB server by using the `vserver cifs create` command.

```
destination_cluster::>vserver cifs create -vserver dvs1 -domain
mydomain.example.com
-cifs-server CIFS1
```

Learn more about `vserver cifs create` in the ONTAP command reference.

8. Stop the destination SVM by using the `vserver stop` command.

```
destination_cluster::> vserver stop -vserver dvs1
[Job 46] Job succeeded: DONE
```

Learn more about `vserver stop` in the ONTAP command reference.

Exclude volumes from an ONTAP SnapMirror SVM DR relationship

By default, all RW data volumes of the source SVM are replicated. If you do not want to protect all the volumes on the source SVM, you can use the `-vserver-dr -protection unprotected` option of the `volume modify` command to exclude volumes from SVM replication.

Steps

1. Exclude a volume from SVM replication:

   `volume modify -vserver SVM -volume volume -vserver-dr-protection unprotected`

   Learn more about `volume modify` in the ONTAP command reference.

   The following example excludes the volume `volA_src` from SVM replication:

   ```
   cluster_src::> volume modify -vserver SVM1 -volume volA_src -vserver-dr
   -protection unprotected
   ```

   If you later want to include a volume in the SVM replication that you originally excluded, run the following command:

   `volume modify -vserver SVM -volume volume -vserver-dr-protection protected`

   The following example includes the volume `volA_src` in the SVM replication:

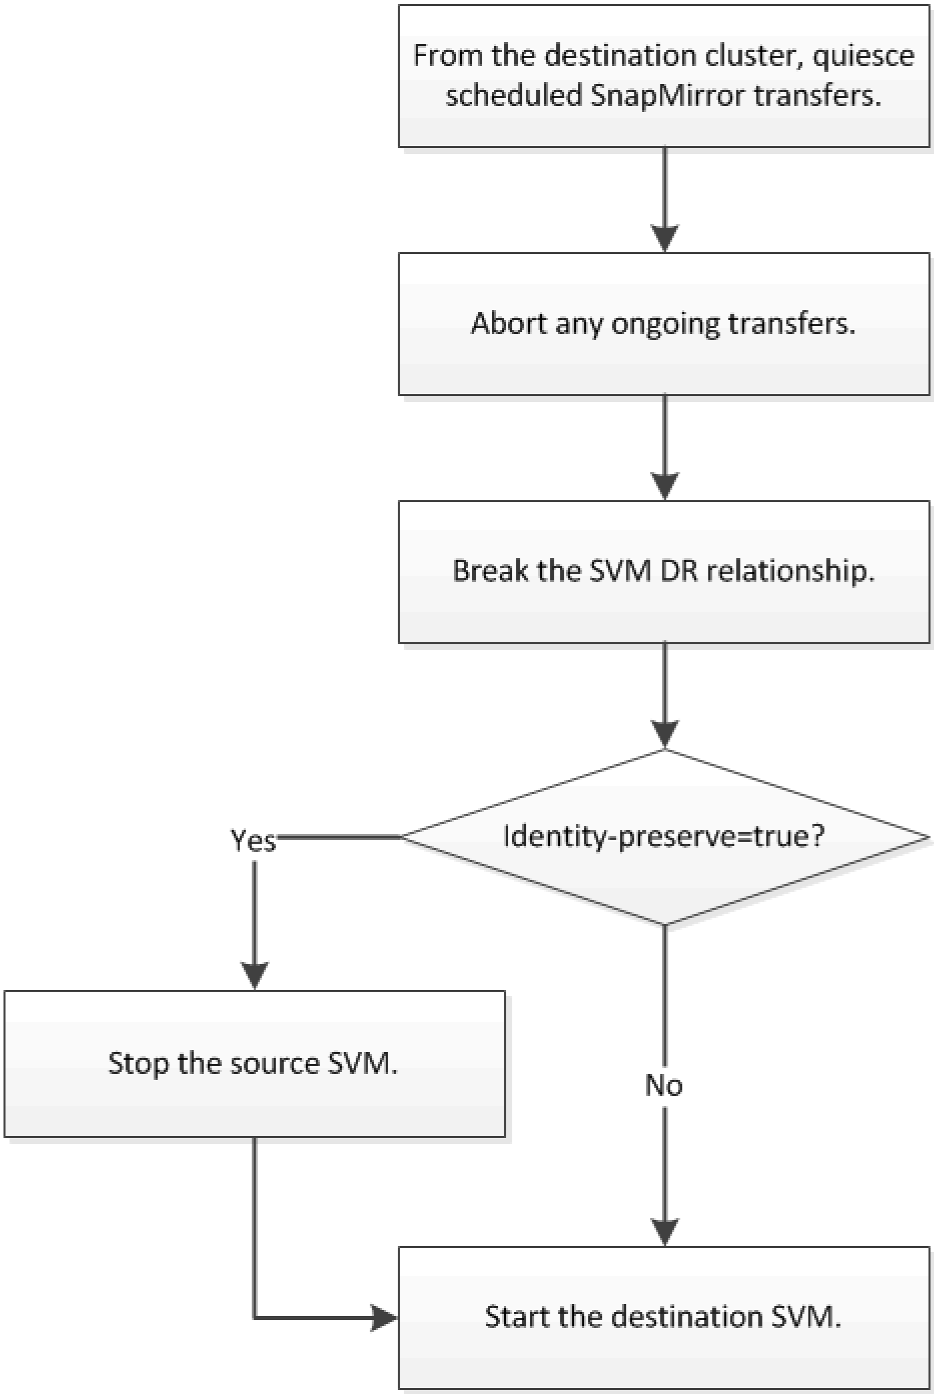
   ```
   cluster_src::> volume modify -vserver SVM1 -volume volA_src -vserver-dr
   -protection protected
   ```

2. Create and initialize the SVM replication relationship as described in Replicating an entire SVM configuration.

Serve data from a SnapMirror SVM DR destination

ONTAP SnapMirror SVM disaster recovery workflow

To recover from a disaster and serve data from the destination SVM, you must activate the destination SVM. Activating the destination SVM involves stopping scheduled SnapMirror transfers, aborting ongoing SnapMirror transfers, breaking the replication relationship, stopping the source SVM, and starting the destination SVM.



Configure the ONTAP SnapMirror SVM destination volume as writable

You need to make SVM destination volumes writeable before you can serve data to clients.

The procedure is largely identical to the procedure for volume replication, with one exception. If you set `-identity-preserve true` when you created the SVM replication relationship, you must stop the source SVM before activating the destination SVM.

About this task

Learn more about the commands described in this procedure in the ONTAP command reference.

> In a disaster recovery scenario, you cannot perform a SnapMirror update from the source SVM to the disaster recovery destination SVM because your source SVM and its data will be inaccessible, and because updates since the last resync might be bad or corrupt.

Beginning with ONTAP 9.8, you can use System Manager to activate a destination storage VM after a disaster. Activating the destination storage VM makes the SVM destination volumes writable and enables you to serve data to clients.

Steps

You can perform this task from System Manager or the ONTAP CLI.

System Manager

1. If the source cluster is accessible, verify that the SVM is stopped: navigate to **Storage > Storage VMs** and check the **State** column for the SVM.
2. If the source SVM state is "Running", stop it: select ⋮ and choose **Stop**.
3. On the destination cluster, locate the desired protection relationship: navigate to **Protection > Relationships**.
4. Hover over the desired source storage VM name, click ⋮, and choose **Activate destination Storage VM**.
5. In the **Activate destination storage VM** window, select **Activate the destination storage VM and break the relationship**.
6. Click **Activate**.

CLI

1. From the destination SVM or the destination cluster, quiesce the SVM to stop scheduled transfers to the destination:

   ```
   snapmirror quiesce -source-path <SVM>: -destination-path <SVM>:
   ```

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

   The following example stops scheduled transfers between the source SVM `svm1` and the destination SVM `svm_backup`:

   ```
   cluster_dst::> snapmirror quiesce -source-path svm1: -destination
   -path svm_backup:
   ```

   Learn more about `snapmirror quiesce` in the ONTAP command reference.

2. From the destination SVM or the destination cluster, stop ongoing transfers to the destination:

   ```
   snapmirror abort -source-path <SVM>: -destination-path <SVM>:
   ```

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

   The following example stops ongoing transfers between the source SVM `svm1` and the destination SVM `svm_backup`:

   ```
   cluster_dst::> snapmirror abort -source-path svm1: -destination-path
   svm_backup:
   ```

Learn more about `snapmirror abort` in the ONTAP command reference.

3. From the destination SVM or the destination cluster, break the replication relationship:

```
snapmirror break -source-path <SVM>: -destination-path <SVM>:
```

> You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example breaks the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1: -destination-path
svm_backup:
```

Learn more about `snapmirror break` in the ONTAP command reference.

4. If you set `-identity-preserve true` when you created the SVM replication relationship, stop the source SVM:

```
vserver stop -vserver <SVM>
```

The following example stops the source SVM `svm1`:

```
cluster_src::> vserver stop svm1
```

5. Start the destination SVM:

```
vserver start -vserver <SVM>
```

The following example starts the destination SVM `svm_backup`:

```
cluster_dst::> vserver start svm_backup
```

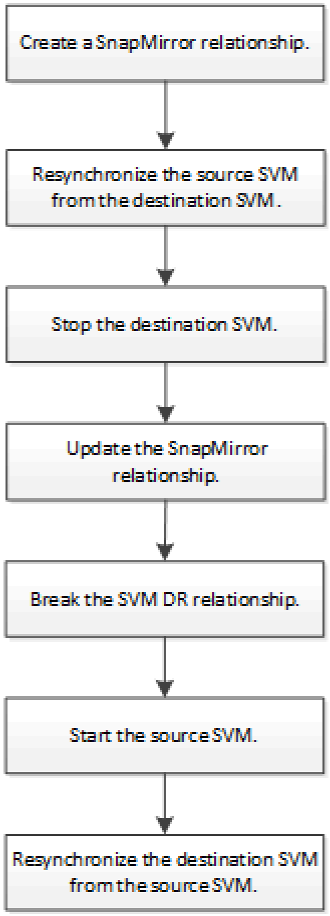
After you finish

Configure SVM destination volumes for data access, as described in Configuring the destination volume for data access.

Reactivate the SnapMirror source SVM

ONTAP SnapMirror source SVM reactivation workflow

If the source SVM exists after a disaster, you can reactivate it and protect it by recreating the SVM disaster recovery relationship.



Reactivate the original ONTAP SnapMirror source SVM

You can reestablish the original data protection relationship between the source and destination SVM when you no longer need to serve data from the destination. The procedure is largely identical to the procedure for volume replication, with one exception. You must stop the destination SVM before reactivating the source SVM.

Before you begin

If you have increased the size of destination volume while serving data from it, before you reactivate the source volume, you should manually increase max-autosize on the original source volume to ensure it can grow sufficiently.

When a destination volume grows automatically

About this task

Beginning with ONTAP 9.11.1, you can reduce resynchronization time during a disaster recovery rehearsal by using the CLI `-quick-resync true` option of the `snapmirror resync` command while performing a reverse resync of an SVM DR relationship. A quick resync can reduce the time it takes to return to production by bypassing the data warehouse rebuild and restore operations. Learn more about `snapmirror resync` in the ONTAP command reference.

> Quick resync does not preserve the storage efficiency of the destination volumes. Enabling quick resync might increase the volume space used by the destination volumes.

This procedure assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.

Beginning with ONTAP 9.8, you can use System Manager to reactivate a source storage VM after a disaster. Reactivating the source storage VM stops the destination storage VM, and it reenables replication from the source to the destination.

When you use System Manager to reactivate the source storage VM, System Manager performs the following operations in the background:

- Creates a reverse SVM DR relationship from the original destination to original source using SnapMirror resync
- Stops the destination SVM
- Updates the SnapMirror relationship
- Breaks the SnapMirror relationship
- Restarts the original SVM
- Issues a SnapMirror resync of the original source back to the original destination
- Cleans up the SnapMirror relationships

Steps

You can perform this task from System Manager or the ONTAP CLI.

System Manager

1. From the destination cluster, click **Protection > Relationships**, and locate the desired protection relationship.
2. Hover over the source relationship name, click ⋮, and select **Reactivate Source Storage VM**.
3. In the **Reactivate source storage VM** window, click **Reactivate**.
4. Under **Relationships**, monitor the source reactivation progress by viewing **Transfer Status** for the protection relationship. When reactivation is complete, the relationship state should return to "Mirrored".

CLI

1. From the original source SVM or the original source cluster, create a reverse SVM DR relationship using the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

   ```
   snapmirror create -source-path <SVM>: -destination-path <SVM>:
   ```

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

   The following example creates a relationship between the SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

   ```
   cluster_src::> snapmirror create -source-path svm_backup:
   -destination-path svm1:
   ```

   Learn more about `snapmirror create` in the ONTAP command reference.

2. From the original source SVM or the original source cluster, run the following command to reverse the data protection relationship:

   ```
   snapmirror resync -source-path <SVM>: -destination-path <SVM>:
   ```

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

   Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

   > The command fails if a common snapshot does not exist on the source and destination. Use `snapmirror initialize` to reinitialize the relationship.

   The following example reverses the relationship between the original source SVM, `svm1`, and the SVM from which you are serving data, `svm_backup`:

```
cluster_src::> snapmirror resync -source-path svm_backup:
-destination-path svm1:
```

Example using -quick-resync option:

```
cluster_src::> snapmirror resync -source-path svm_backup:
-destination-path svm1: -quick-resync true
```

3. When you are ready to reestablish data access to the original source SVM, stop the original destination SVM to disconnect any clients currently connected to the original destination SVM.

```
vserver stop -vserver <SVM>
```

The following example stops the original destination SVM which is currently serving data:

```
cluster_dst::> vserver stop svm_backup
```

4. Verify that the original destination SVM is in the stopped state by using the `vserver show` command.

```
cluster_dst::> vserver show
                                  Admin      Operational Root
Vserver       Type    Subtype     State      State       Volume
Aggregate
--------      ------- ---------- ---------- ----------- ----------
----------
svm_backup    data    default     stopped    stopped     rv
aggr1
```

5. From the original source SVM or the original source cluster, run the following command to perform the final update of the reversed relationship to transfer all changes from the original destination SVM to the original source SVM:

```
snapmirror update -source-path <SVM>: -destination-path <SVM>:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example updates the relationship between the original destination SVM from which you are serving data,`svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror update -source-path svm_backup:
-destination-path svm1:
```

Learn more about `snapmirror update` in the ONTAP command reference.

6. From the original source SVM or the original source cluster, run the following command to stop scheduled transfers for the reversed relationship:

   ```
   snapmirror quiesce -source-path <SVM>: -destination-path <SVM>:
   ```

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

   The following example stops scheduled transfers between the SVM you are serving data from, `svm_backup`, and the original SVM, `svm1`:

   ```
   cluster_src::> snapmirror quiesce -source-path svm_backup:
   -destination-path svm1:
   ```

7. When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship:

   ```
   snapmirror break -source-path <SVM>: -destination-path <SVM>:
   ```

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

   The following example breaks the relationship between the original destination SVM from which you were serving data, `svm_backup`, and the original source SVM, `svm1`:

   ```
   cluster_src::> snapmirror break -source-path svm_backup:
   -destination-path svm1:
   ```

   Learn more about `snapmirror break` in the ONTAP command reference.

8. If the original source SVM was previously stopped, from the original source cluster, start the original source SVM:

   ```
   vserver start -vserver <SVM>
   ```

The following example starts the original source SVM:

```
cluster_src::> vserver start svm1
```

9. From the original destination SVM or the original destination cluster, reestablish the original data protection relationship:

```
snapmirror resync -source-path <SVM>: -destination-path <SVM>:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example reestablishes the relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1: -destination
-path svm_backup:
```

10. From the original source SVM or the original source cluster, run the following command to delete the reversed data protection relationship:

```
snapmirror delete -source-path <SVM>: -destination-path <SVM>:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example deletes the reversed relationship between the original destination SVM, `svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror delete -source-path svm_backup:
-destination-path svm1:
```

11. From the original destination SVM or the original destination cluster, release the reversed data protection relationship:

```
snapmirror release -source-path <SVM>: -destination-path <SVM>:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example releases the reversed relationship between the original destination SVM,

svm_backup, and the original source SVM, `svm1`

```
cluster_dst::> snapmirror release -source-path svm_backup:
-destination-path svm1:
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created.

Learn more about `snapmirror show` in the ONTAP command reference.

- snapmirror create
- snapmirror delete
- snapmirror initialize
- snapmirror quiesce
- snapmirror release
- snapmirror resync

Reactivate the original ONTAP SnapMirror source SVM for FlexGroup volumes

You can reestablish the original data protection relationship between the source and destination SVM when you no longer need to serve data from the destination. To reactivate the original source SVM when you are using FlexGroup volumes, you need to perform some additional steps, including deleting the original SVM DR relationship and releasing the original relationship before you reverse the relationship. You also need to release the reversed relationship and recreate the original relationship before stopping scheduled transfers.

Steps

1. From the original destination SVM or the original destination cluster, delete the original SVM DR relationship:

   `snapmirror delete -source-path SVM: -destination-path SVM:`

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   The following example deletes the original relationship between the original source SVM, svm1, and the original destination SVM, `svm_backup`:

   ```
   cluster_dst::> snapmirror delete -source-path svm1: -destination-path
   svm_backup:
   ```

2. From the original source SVM or the original source cluster, release the original relationship while keeping the snapshots intact:

   `snapmirror release -source-path SVM: -destination-path SVM: -relationship-info -only true`

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   The following example releases the original relationship between the original source SVM, svm1, and the original destination SVM, `svm_backup`.

   ```
   cluster_src::> snapmirror release -source-path svm1: -destination-path
   svm_backup: -relationship-info-only true
   ```

3. From the original source SVM or the original source cluster, create a reverse SVM DR relationship using the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

   `snapmirror create -source-path SVM: -destination-path SVM:`

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   The following example creates a relationship between the SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

   ```
   cluster_src::> snapmirror create -source-path svm_backup: -destination
   -path svm1:
   ```

4. From the original source SVM or the original source cluster, run the following command to reverse the data protection relationship:

   `snapmirror resync -source-path` *`SVM`*`: -destination-path` *`SVM`*`:`

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

   > The command fails if a common snapshot does not exist on the source and destination. Use `snapmirror initialize` to reinitialize the relationship.

   The following example reverses the relationship between the original source SVM, `svm1`, and the SVM from which you are serving data, `svm_backup`:

```
cluster_src::> snapmirror resync -source-path svm_backup: -destination
-path svm1:
```

5. When you are ready to reestablish data access to the original source SVM, stop the original destination SVM to disconnect any clients currently connected to the original destination SVM.

   `vserver stop -vserver SVM`

   The following example stops the original destination SVM which is currently serving data:

```
cluster_dst::> vserver stop svm_backup
```

6. Verify that the original destination SVM is in the stopped state by using the `vserver show` command.

```
cluster_dst::> vserver show
                                    Admin      Operational  Root
Vserver         Type    Subtype     State      State        Volume
Aggregate
--------        ------- ---------- ---------- ----------- ----------
----------
svm_backup      data    default     stopped    stopped      rv
aggr1
```

7. From the original source SVM or the original source cluster, run the following command to perform the final update of the reversed relationship to transfer all changes from the original destination SVM to the original source SVM:

   `snapmirror update -source-path SVM: -destination-path SVM:`

   You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   The following example updates the relationship between the original destination SVM from which you are serving data,`svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror update -source-path svm_backup: -destination
-path svm1:
```

   Learn more about `snapmirror update` in the ONTAP command reference.

8. From the original source SVM or the original source cluster, run the following command to stop scheduled transfers for the reversed relationship:

   `snapmirror quiesce -source-path SVM: -destination-path SVM:`

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

The following example stops scheduled transfers between the SVM you are serving data from, `svm_backup`, and the original SVM, `svm1`:

```
cluster_src::> snapmirror quiesce -source-path svm_backup: -destination
-path svm1:
```

Learn more about `snapmirror quiesce` in the ONTAP command reference.

9. When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship:

   `snapmirror break -source-path SVM: -destination-path SVM:`

   You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   The following example breaks the relationship between the original destination SVM from which you were serving data, `svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror break -source-path svm_backup: -destination
-path svm1:
```

   Learn more about `snapmirror break` in the ONTAP command reference.

10. If the original source SVM was previously stopped, from the original source cluster, start the original source SVM:

    `vserver start -vserver SVM`

    The following example starts the original source SVM:

```
cluster_src::> vserver start svm1
```

11. From the original source SVM or the original source cluster, delete the reversed SVM DR relationship:

    `snapmirror delete -source-path SVM: -destination-path SVM:`

    You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

    The following example deletes the reversed relationship between the original destination SVM, svm_backup, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror delete -source-path svm_backup: -destination
-path svm1:
```

12. From the original destination SVM or the original destination cluster, release the reversed relationship while keeping the snapshots intact:

    `snapmirror release -source-path SVM: -destination-path SVM: -relationship-info -only true`

    > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

    The following example releases the reversed relationship between the original destination SVM, svm_backup, and the original source SVM, svm1:

    ```
    cluster_dst::> snapmirror release -source-path svm_backup: -destination
    -path svm1: -relationship-info-only true
    ```

13. From the original destination SVM or the original destination cluster, recreate the original relationship. Use the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

    `snapmirror create -source-path SVM: -destination-path SVM:`

    > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

    The following example creates a relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

    ```
    cluster_dst::> snapmirror create -source-path svm1: -destination-path
    svm_backup:
    ```

14. From the original destination SVM or the original destination cluster, reestablish the original data protection relationship:

    `snapmirror resync -source-path` *`SVM`*`: -destination-path` *`SVM`*`:`

    > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

    The following example reestablishes the relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1: -destination-path
svm_backup:
```

Resynchronize the data on an ONTAP SnapMirror destination SVM

ONTAP 9.11.1 introduces an option to bypass a full data warehouse rebuild when you perform a disaster recovery rehearsal, enabling you to return to production faster.

Beginning with ONTAP 9.8, you can use System Manager to resynchronize the data and configuration details from the source storage VM to the destination storage VM in a broken protection relationship and reestablish the relationship.

You perform the resync operation only from the destination of the original relationship. The resync deletes any data in the destination storage VM that is newer than the data in the source storage VM.

Steps

You can use System Manager or the ONTAP CLI to perform this task.

System Manager

1. From the destination, select the desired protection relationship: click **Protection > Relationships**.
2. Optionally, select **Perform a quick resync** to bypass a full data warehouse rebuild during a disaster recovery rehearsal.
3. Click ⋮ and click **Resync**.
4. Under **Relationships**, monitor the resynchronization progress by viewing **Transfer Status** for the relationship.

CLI

1. From the destination cluster, resynchronize the relationship:

```
snapmirror resync -source-path <svm>: -destination-path <svm>:
-quick-resync true|false
```

Related information

- snapmirror resync

Convert an ONTAP SnapMirror volume DR relationship to an SVM DR relationship

You can convert replication relationships between volumes to a replication relationship between the storage virtual machines (SVMs) that own the volumes, provided that each volume on the source (except the root volume) is being replicated, and each volume on the source (including the root volume) has the same name as the volume on the destination.

About this task

Use the `volume rename` command when the SnapMirror relationship is idle to rename destination volumes if necessary. Learn more about `volume rename` in the ONTAP command reference.

Steps

1. From the destination SVM or the destination cluster, run the following command to resync the source and destination volumes:

   `snapmirror resync -source-path <SVM:volume> -destination-path <SVM:volume> -type DP|XDP -policy <policy>`

   Learn more about `snapmirror resync` in the ONTAP command reference.

   > Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

   The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA` on `svm_backup`:

   ```
   cluster_dst::> snapmirror resync -source-path svm1:volA -destination
   -path svm_backup:volA
   ```

2. Create an SVM replication relationship between the source and destination SVMs, as described in Replicating SVM configurations.

   You must use the `-identity-preserve true` option of the `snapmirror create` command when you create your replication relationship.

   Learn more about `snapmirror create` in the ONTAP command reference.

3. Stop the destination SVM:

   `vserver stop -vserver SVM`

   Learn more about `vserver stop` in the ONTAP command reference.

   The following example stops the destination SVM `svm_backup`:

   ```
   cluster_dst::> vserver stop svm_backup
   ```

4. From the destination SVM or the destination cluster, run the following command to resync the source and destination SVMs:

```
snapmirror resync -source-path <SVM>: -destination-path <SVM>: -type DP|XDP
-policy <policy>
```

> You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.
>
> Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

The following example resyncs the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1: -destination-path
svm_backup:
```

Related information

- snapmirror create
- snapmirror resync

Delete an ONTAP SnapMirror SVM replication relationship

You can use the `snapmirror delete` and `snapmirror release` commands to delete an SVM replication relationship. You can then delete unneeded destination volumes manually. Learn more about the commands described in this procedure in the ONTAP command reference.

About this task

The `snapmirror release` command deletes any SnapMirror-created snapshots from the source. You can use the `-relationship-info-only` option to preserve the snapshots.

Steps

1. Run the following command from the destination SVM or the destination cluster to break the replication relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

> You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

The following example breaks the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1: -destination-path
svm_backup:
```

Learn more about `snapmirror break` in the ONTAP command reference.

2. Run the following command from the destination SVM or the destination cluster to delete the replication relationship:

   `snapmirror delete -source-path *SVM*: -destination-path *SVM*:`

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   The following example deletes the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

   ```
   cluster_dst::> snapmirror delete -source-path svm1: -destination-path
   svm_backup:
   ```

   Learn more about `snapmirror delete` in the ONTAP command reference.

3. Run the following command from the source cluster or source SVM to release the replication relationship information from the source SVM:

   `snapmirror release -source-path *SVM*: -destination-path *SVM*:`

   > You must enter a colon (:) after the SVM name in the `-source-path` and `-destination -path` options. See the example below.

   The following example releases information for the specified replication relationship from the source SVM `svm1`:

   ```
   cluster_src::> snapmirror release -source-path svm1: -destination-path
   svm_backup:
   ```

   Learn more about `snapmirror release` in the ONTAP command reference.

Manage SnapMirror root volume replication

Learn about ONTAP SnapMirror root volume replication

Every SVM in a NAS environment has a unique namespace. The SVM *root volume,* containing operating system and related information, is the entry point to the namespace hierarchy. To ensure that data remains accessible to clients in the event of a node outage or failover, you should create a load-sharing mirror copy of the SVM root volume.

The main purpose of load-sharing mirrors for SVM root volumes is no longer for load sharing; instead, their purpose is for disaster recovery.

- If the root volume is temporarily unavailable, the load-sharing mirror automatically provides read-only access to root volume data.
- If the root volume is permanently unavailable, you can promote one of the load-sharing volumes to provide write access to root volume data.

Create and initialize ONTAP load-sharing mirror relationships

You should create a load-sharing mirror (LSM) for each SVM root volume that serves NAS data in the cluster. For clusters consisting of two or more HA pairs, you should consider load-sharing mirrors of SVM root volumes to ensure the namespace remains accessible to clients in the event that both nodes of an HA pair fail. Load-sharing mirrors are not suitable for clusters consisting of a single HA pair.

Before you begin

Beginning with ONTAP 9.16.1, when you create a load-sharing mirror relationship, the destination SVM cannot have a storage limit enabled.

About this task

If you create an LSM on the same node, and the node is unavailable, you have a single point of failure, and you do not have a second copy to ensure the data remains accessible to clients. But when you create the LSM on a node other than the one containing the root volume, or on a different HA pair, your data is still accessible in the event of an outage.

For example, in a four-node cluster with a root volume on three nodes:

- For the root volume on HA 1 node 1, create the LSM on HA 2 node 1 or HA 2 node 2.
- For the root volume on HA 1 node 2, create the LSM on HA 2 node 1 or HA 2 node 2.
- For the root volume on HA 2 node 1, create the LSM on HA 1 node 1 or HA 1 node 2.

Steps

1. Create a destination volume for the LSM:

   ```
   volume create -vserver <SVM> -volume <volume> -aggregate <aggregate>
   -type DP -size <size>
   ```

   The destination volume should be the same or greater in size than the root volume.

   It is a best practice to name the root and destination volume with suffixes, such as `_root` and `_m1`.

   Learn more about `volume create` in the ONTAP command reference.

   The following example creates a load-sharing mirror volume for the root volume `svm1_root` in `cluster_src`:

```
cluster_src:> volume create -vserver svm1 -volume svm1_m1 -aggregate
aggr_1 -size 1gb -state online -type DP
```

2. Create a replications job schedule.
3. Create a load-sharing mirror relationship between the SVM root volume and the destination volume for the LSM:

```
snapmirror create -source-path <SVM:volume> -destination-path
<SVM:volume> -type LS -schedule <schedule>
```

The following example creates a load-sharing mirror relationship between the root volume `svm1_root` and the load-sharing mirror volume `svm1_m1`:

```
cluster_src::> snapmirror create -source-path svm1:svm1_root
-destination-path svm1:svm1_m1 -type LS -schedule hourly
```

The type attribute of the load-sharing mirror changes from `DP` to `LS`.

Learn more about `snapmirror create` in the ONTAP command reference.

4. Initialize the load-sharing mirror:

```
snapmirror initialize-ls-set -source-path <SVM:volume>
```

The following example initializes the load-sharing mirror for the root volume `svm1_root`:

```
cluster_src::> snapmirror initialize-ls-set -source-path svm1:svm1_root
```

Learn more about `snapmirror initialize` in the ONTAP command reference.

Update an ONTAP load-sharing mirror relationship

Load-sharing mirror (LSM) relationships are updated automatically for SVM root volumes after a volume in the SVM is mounted or unmounted, and during `volume create` operations that include the `junction-path` option. You can manually update a LSM relationship if you want it updated before the next scheduled update.

Load-sharing mirror relationships update automatically in the following circumstances:

- It’s time for a scheduled update
- A mount or unmount operation is performed on a volume in the SVM root volume

* A `volume create` command is issued that includes the `junction-path` option

  Learn more about `volume create` in the [ONTAP command reference](#).

Step

1. Update a load-sharing mirror relationship manually:

   You must replace the variables in angle brackets with the required values before running this command.

   ```
   snapmirror update-ls-set -source-path <SVM:volume>
   ```

   The following example updates the load-sharing mirror relationship for the root volume `svm1_root`:

   ```
   cluster_src::> snapmirror update-ls-set -source-path svm1:svm1_root
   ```

   Learn more about `snapmirror update` in the [ONTAP command reference](#).

Promote an ONTAP load-sharing mirror

If a root volume is permanently unavailable, you can promote the load-sharing mirror (LSM) volume to provide write access to root volume data.

Before you begin

You must use advanced privilege level commands for this task.

Steps

1. Change to advanced privilege level:

   ```
   set -privilege advanced
   ```

2. Promote an LSM volume:

   You must replace the variables in angle brackets with the required values before running this command.

   ```
   snapmirror promote -destination-path <SVM:volume>
   ```

   The following example promotes the volume `svm1_m2` as the new SVM root volume:

```
cluster_src::*> snapmirror promote -destination-path svm1:svm1_m2

Warning: Promote will delete the offline read-write volume
         cluster_src://svm1/svm1_root and replace it with
         cluster_src://svm1/svm1_m2. Because the volume is offline,
         it is not possible to determine whether this promote will
         affect other relationships associated with this source.
Do you want to continue? {y|n}: y
```

Enter `y`. ONTAP makes the LSM volume a read/write volume, and deletes the original root volume if it is accessible.

> The promoted root volume might not have all of the data that was in the original root volume if the last update did not occur recently.

Learn more about `snapmirror promote` in the ONTAP command reference.

3. Return to admin privilege level:

```
set -privilege admin
```

4. Rename the promoted volume following the naming convention you used for the root volume:

You must replace the variables in angle brackets with the required values before running this command.

```
volume rename -vserver <SVM> -volume <volume> -newname <new_name>
```

The following example renames the promoted volume `svm1_m2` with the name `svm1_root`:

```
cluster_src::> volume rename -vserver svm11 -volume svm1_m2 -newname
svm1_root
```

5. Protect the renamed root volume, as described in step 3 through step 4 in Creating and initializing load-sharing mirror relationships.

Back up to the cloud

Install an ONTAP SnapMirror cloud license

SnapMirror cloud relationships can be orchestrated using pre-qualified third-party backup applications. Beginning with ONTAP 9.9.1, you can also use System Manager to orchestrate SnapMirror cloud replication. Both SnapMirror and SnapMirror cloud capacity licenses are required when using System Manager to orchestrate on-premises ONTAP to object storage backups. You will also need to request and install the SnapMirror cloud API license.

About this task

The SnapMirror cloud and SnapMirror S3 licenses are cluster licenses, not node licenses, so they are *not* delivered with the ONTAP One license bundle. These licenses are included in the separate ONTAP One Compatibility bundle. If you want to enable SnapMirror cloud, you need to request this bundle.

Additionally, System Manager orchestration of SnapMirror cloud backups to object storage requires a SnapMirror cloud API key. This API license is a single-instance cluster-wide license, meaning it does not need to be installed on every node in the cluster.

Steps

You need to request and download the ONTAP One Compatibility bundle and the SnapMirror cloud API license and then install them using System Manager.

1. Locate and record the cluster UUID for the cluster you want to license.

   The cluster UUID is required when you submit your request to order the ONTAP One Compatibility bundle for your cluster.

2. Contact your NetApp sales team and request the ONTAP One Compatibility bundle.
3. Request the SnapMirror cloud API license by following the instructions provided on the NetApp Support Site.

   Request SnapMirror cloud API license key

4. When you've received and downloaded the license files, use System Manager to upload the ONTAP Cloud Compatibility NLF and the SnapMirror cloud API NLF to the cluster:
   a. Click **Cluster > Settings**.
   b. In the **Settings** window, click **Licenses**.
   c. In the **Licenses** window, click + Add.
   d. In the **Add License** dialog box, click **Browse** to select the NLF you downloaded, and then click **Add** to upload the file to the cluster.

NetApp Software License Search

Back up data to the cloud using ONTAP SnapMirror

Beginning with ONTAP 9.9.1, you can back up your data to the cloud and to restore your data from cloud storage to a different volume by using System Manager. You can use either StorageGRID or ONTAP S3 as your cloud object store.

Beginning with ONTAP 9.16.1:

* SnapMirror cloud backup supports fan-out relationships. This means that SnapMirror backups can be created simultaneously on two different object stores. With ONTAP 9.16.1, SnapMirror cloud supports two fan-out relationships. Fan-outs can be to two object stores and to one or two buckets in two different object

stores. Attempts to create more than two fan-out relationships will fail.

- SnapMirror cloud supports backups of volumes migrated to the cloud using a more efficient synchronization process using existing ONTAP REST APIs. The functionality supports SnapMirror cloud backups from a migrated volume in the cloud to the same destination object store endpoint without the need for performing a re-baseline operation. Both FlexVol and FlexGroup volumes are supported.

Before using the SnapMirror cloud feature, you should request a SnapMirror cloud API license key from the NetApp Support Site: Request SnapMirror cloud API license key.
Following the instructions, you should provide a simple description of your business opportunity and request the API key by sending an email to the provided email address. You should receive an email response within 24 hours with further instructions on how to acquire the API key.

Add a cloud object store

Before you configure SnapMirror cloud backups, you need to add a StorageGRID or ONTAP S3 cloud object store.

Steps

1. Click **Protection > Overview > Cloud Object Stores**.
2. Click + Add.

Back up using the default policy

You can quickly configure a SnapMirror cloud backup for an existing volume using the default cloud protection policy, DailyBackup.

Steps

1. Click **Protection > Overview** and select **Back Up Volumes to Cloud**.
2. If this is your first time backing up to the cloud, enter your SnapMirror cloud API license key in the license field as indicated.
3. Click **Authenticate and Continue**.
4. Select a source volume.
5. Select a cloud object store.
6. Click **Save**.

Create a custom cloud backup policy

If you do not want to use the default DailyBackup cloud policy for your SnapMirror cloud backups, you can create your own policy.

Steps

1. Click **Protection > Overview > Local Policy Settings** and select **Protection Policies**.
2. Click **Add** and enter the new policy details.
3. In the **Policy Type** section, select **Back up to Cloud** to indicate that you are creating a cloud policy.
4. Click **Save**.

Create a backup from the Volumes page

You can use the System Manager **Volumes** page when you want to select and create cloud backups for multiple volumes at one time or when you want to use a custom protection policy.

Steps

1. Click **Storage > Volumes**.
2. Select the volumes you want to back up to the cloud, and click **Protect**.
3. In the **Protect Volume** window, click **More Options**.
4. Select a policy.

   You can select the default policy, DailyBackup, or a custom cloud policy you created.

5. Select a cloud object store.
6. Click **Save**.

Restore from the cloud

You can use System Manager to restore backed up data from cloud storage to a different volume on the source cluster.

> If you are using ONTAP 9.16.1 or later and you are performing a SnapMirror cloud single file restore to a FlexGroup volume, you should only restore files to a new directory in the FlexGroup volume, and granular data must be set to `advanced` on the destination FlexGroup volume. For more information about setting the `-granular-data advanced` option, see Balance ONTAP FlexGroup volumes by redistributing file data.

Steps

1. From the source Cluster of a SnapMirror-to-Cloud relationship, click **Storage > Volumes**.
2. Select the volume you want to restore.
3. Select the **Back Up to Cloud** tab.
4. Click ⋮ next to the source volume you want to restore to display the menu, and select **Restore**.
5. Under **Source**, select a storage VM and then enter the name of the volume to which you want the data restored.
6. Under **Destination**, select the snapshot you want to restore.
7. Click **Save**.

Delete a SnapMirror cloud relationship

You can use System Manager to delete a cloud relationship.

Steps

1. Click **Storage > Volumes** and select the volume you want to delete.
2. Click ⋮ next to the source volume and select **Delete**.
3. Select **Delete the cloud object store endpoint (optional)** if you want to delete the cloud object store endpoint.
4. Click **Delete**.

Remove a cloud object store

You can use System Manager to remove a cloud object store if it is not part of a cloud backup relationship. When a cloud object store is part of a cloud backup relationship, it cannot be deleted.

Steps

1. Click **Protection > Overview > Cloud Object Stores**.
2. Select the object store you want to delete, click ⋮ and select **Delete**.

Back up data using BlueXP backup and recovery

Beginning with ONTAP 9.9.1, you can use System Manager to back up data in the cloud using BlueXP backup and recovery (formerly Cloud Backup service).

BlueXP backup and recovery supports FlexVol read-write volumes and data-protection (DP) volumes. Beginning with ONTAP 9.12.1, BlueXP backup and recovery supports FlexGroup volumes and SnapLock volumes.

Learn more about BlueXP backup and recovery.

Before you begin

You should perform the following procedures to establish an account in BlueXP. For the service account, you need to create the role as "Account Admin". (Other service account roles do not have the required privileges needed to establish a connection from System Manager.)

1. Create an account in BlueXP.
2. Create a connector in BlueXP with one of the following cloud providers:
   - Microsoft Azure
   - Amazon Web Services (AWS)
   - Google Cloud Platform (GCP)
   - StorageGRID (ONTAP 9.10.1)

   > Beginning with ONTAP 9.10.1, you can select StorageGRID as a cloud backup provider, but only if BlueXP is deployed on premises. The BlueXP Connector must be installed on premises and available through the BlueXP software-as-a-service (SaaS) application.

3. Subscribe to BlueXP backup and recovery in BlueXP (requires the appropriate license).
4. Generate an access key and a secret key using BlueXP.

Register the cluster with BlueXP

You can register the cluster with BlueXP by using either BlueXP or System Manager.

Steps

1. In System Manager, go to **Protection Overview**.
2. Under **BlueXP backup and recovery**, provide the following details:
   - Client ID
   - Client secret key

3. Select **Register and Continue**.

Enable BlueXP backup and recovery

After the cluster is registered with BlueXP, you need to enable the BlueXP backup and recovery and initiate the first backup to the cloud.

Steps

1. In System Manager, select **Protection > Overview**, then scroll to the **Cloud Backup Service** section.
2. Enter the **Client ID** and **Client Secret**.

   > Beginning with ONTAP 9.10.1, you can learn about the cost of using the cloud by selecting **Learn more about the cost of using the cloud**.

3. Select **Connect and Enable Cloud Backup Service**.
4. On the **Enable BlueXP backup and recovery** page, provide the following details, depending on the provider you selected.

For this cloud provider…	Enter the following data…
Azure	• Azure Subscription ID • Region • Resource group name (existing or new)
AWS	• AWS Account ID • Access key • Secret key • Region
Google Cloud Project (GCP)	• Google Cloud Project name • Google Cloud Access key • Google Cloud Secret key • Region
StorageGRID (ONTAP 9.10.1 and later, and only for on-premises deployment of BlueXP)	• Server • SG Access Key • SG Secret Key

5. Select a **Protection policy**:
   - **Existing policy**: Choose an existing policy.
   - **New Policy**: Specify a name and set up a transfer schedule.

   > Beginning with ONTAP 9.10.1, you can specify whether you want to enable archiving with Azure or AWS.

> If you enable archiving for a volume with Azure or AWS, you cannot disable the archiving.

If you enable archiving for Azure or AWS, specify the following:

   ▪ The number of days after which the volume is archived.
   ▪ The number of backups to retain in the archive. Specify "0" (zero) to archive up to the latest backup.
   ▪ For AWS, select the archive storage class.

6. Select the volumes you want to back up.
7. Select **Save**.

Edit the protection policy used for BlueXP backup and recovery

You can change which protection policy is used with BlueXP backup and recovery.

Steps

1. In System Manager, select **Protection > Overview**, then scroll to the **Cloud Backup Service** section.
2. Select ⋮, then **Edit**.
3. Select a **Protection policy**:
   ◦ **Existing policy**: Choose an existing policy.
   ◦ **New Policy**: Specify a name and set up a transfer schedule.

   > Beginning with ONTAP 9.10.1, you can specify whether you want to enable archiving with Azure or AWS.

   > If you enable archiving for a volume with Azure or AWS, you cannot disable the archiving.

   If you enable archiving for Azure or AWS, specify the following:

   ▪ The number of days after which the volume is archived.
   ▪ The number of backups to retain in the archive. Specify "0" (zero) to archive up to the latest backup.
   ▪ For AWS, select the archive storage class.

4. Select **Save**.

Protect new volumes or LUNs on the cloud

When you create a new volume or LUN, you can establish a SnapMirror protection relationship that enables backing up to the cloud for the volume or LUN.

Before you begin

- You should have a SnapMirror license.
- Intercluster LIFs should be configured.
- NTP should be configured.

- Cluster must be running ONTAP 9.9.1 or later.

About this task

You cannot protect new volumes or LUNs on the cloud for the following cluster configurations:

- The cluster cannot be in a MetroCluster environment.
- SVM-DR is not supported.
- FlexGroup volumes cannot be backed up using BlueXP backup and recovery.

Steps

1. When provisioning a volume or LUN, on the **Protection** page in System Manager, select the checkbox labeled **Enable SnapMirror (Local or Remote)**.
2. Select the BlueXP backup and recovery policy type.
3. If the BlueXP backup and recovery is not enabled, select **Enable Backup using BlueXP backup and recovery**.

Protect existing volumes or LUNs on the cloud

You can establish a SnapMirror protection relationship for existing volumes and LUNs.

Steps

1. Select an existing volume or LUN, and select **Protect**.
2. On the **Protect Volumes** page, specify **Backup using BlueXP backup and recovery** for the protection policy.
3. Select **Protect**.
4. On the **Protection** page, select the checkbox labeled **Enable SnapMirror (Local or Remote)**.
5. Select **Connect and enable BlueXP backup and recovery**.

Restore data from backup files

You can perform backup management operations, such as restoring data, updating relationships, and deleting relationships, only when using the BlueXP interface. Refer to Restoring data from backup files for more information.

Archive and compliance using SnapLock technology

Learn about ONTAP SnapLock

SnapLock is a high-performance compliance solution for organizations that use WORM storage to retain files in unmodified form for regulatory and governance purposes.

SnapLock helps to prevent deletion, change, or renaming of data to meet regulations such as SEC 17a-4(f), HIPAA, FINRA, CFTC, and GDPR. With SnapLock, you can create special-purpose volumes in which files can be stored and committed to a non-erasable, non-writable state either for a designated retention period or indefinitely. SnapLock allows this retention to be performed at the file level through standard open file protocols such as CIFS and NFS. The supported open file protocols for SnapLock are NFS (versions 2, 3, and 4) and CIFS (SMB 1.0, 2.0, and 3.0).

Using SnapLock, you commit files and snapshots to WORM storage, and set retention periods for WORM-protected data. SnapLock WORM storage uses NetApp snapshot technology and can leverage SnapMirror replication, and SnapVault backups as the base technology for providing backup recovery protection for data. Learn more about WORM storage: Compliant WORM storage using NetApp SnapLock - TR-4526.

You can use an application to commit files to WORM over NFS or CIFS, or use the SnapLock autocommit feature to commit files to WORM automatically. You can use a *WORM appendable file* to retain data that is written incrementally, like log information. For more information see Use volume append mode to create WORM appendable files.

SnapLock supports data protection methods that should satisfy most compliance requirements:

- You can use SnapLock for SnapVault to WORM-protect snapshots on secondary storage. See Commit snapshots to WORM.
- You can use SnapMirror to replicate WORM files to another geographic location for disaster recovery. See Mirror WORM files.

SnapLock is a license-based feature of NetApp ONTAP. A single license entitles you to use SnapLock in strict Compliance mode, to satisfy external mandates like SEC Rule 17a-4(f), and a looser Enterprise mode, to meet internally mandated regulations for the protection of digital assets. SnapLock licenses are part of the ONTAP One software suite.

SnapLock is supported on all AFF and FAS systems as well as ONTAP Select. SnapLock is not a software-only solution; it is an integrated hardware and software solution. This distinction is important for strict WORM regulations such as SEC 17a-4(f), which requires an integrated hardware and software solution. For more information, refer to SEC Guidance to Broker-Dealers on the Use of Electronic Storage Media.

What you can do with SnapLock

After you configure SnapLock, you can complete the following tasks:

- Commit files to WORM
- Commit snapshots to WORM for secondary storage
- Mirror WORM files for disaster recovery
- Retain WORM files during litigation using Legal Hold
- Delete WORM files using the privileged delete feature
- Set the file retention period
- Move a SnapLock volume
- Lock a snapshot for protection against ransomware attacks
- Review snapLock use with the Audit Log
- Use SnapLock APIs

SnapLock Compliance and Enterprise modes

SnapLock Compliance and Enterprise modes differ mainly in the level at which each mode protects WORM files:

SnapLock mode	Protection level	WORM file deleting during retention

Compliance mode	At the disk level	Cannot be deleted
Enterprise mode	At the file level	Can be deleted by the compliance administrator using an audited “privileged delete” procedure

After the retention period has elapsed, you are responsible for deleting any files you no longer need. Once a file has been committed to WORM, whether under Compliance or Enterprise mode, it cannot be modified, even after the retention period has expired.

You cannot move a WORM file during or after the retention period. You can copy a WORM file, but the copy will not retain its WORM characteristics.

The following table shows the differences in capabilities supported by SnapLock Compliance and Enterprise modes:

Capability	SnapLock Compliance	SnapLock Enterprise
Enable and delete files using privileged delete	No	Yes
Reinitialize disks	No	Yes
Destroy SnapLock aggregates and volumes during retention period	No	Yes, with the exception of the SnapLock audit log volume
Rename aggregates or volumes	No	Yes
Use non-NetApp disks	No	No
Use the SnapLock volume for audit logging	Yes	Yes, beginning with ONTAP 9.5

Supported and unsupported features with SnapLock

The following table shows the features that are supported with SnapLock Compliance mode, SnapLock Enterprise mode, or both:

Feature	Supported with SnapLock Compliance	Supported with SnapLock Enterprise
Consistency Groups	No	No
Encrypted volumes	Yes, learn more about Encryption and SnapLock.	Yes, learn more about Encryption and SnapLock.

FabricPools on SnapLock aggregates	No	Yes, beginning with ONTAP 9.8. Learn more about FabricPool on SnapLock Enterprise aggregates.
Flash Pool aggregates	Yes.	Yes.
FlexClone	You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.	You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.
FlexGroup volumes	Yes, beginning with ONTAP 9.11.1. Learn more about FlexGroup volumes.	Yes, beginning with ONTAP 9.11.1. Learn more about FlexGroup volumes.
LUNs	No. Learn more about LUN support with SnapLock.	No. Learn more about LUN support with SnapLock.
MetroCluster configurations	Yes, beginning with ONTAP 9.3. Learn more about MetroCluster support.	Yes, beginning with ONTAP 9.3. Learn more about MetroCluster support.
Multi-admin verification (MAV)	Yes, beginning with ONTAP 9.13.1. Learn more about MAV support.	Yes, beginning with ONTAP 9.13.1. Learn more about MAV support.
SAN	No	No
Single-file SnapRestore	No	Yes
SnapMirror active sync	No	No
SnapRestore	No	Yes
SMTape	No	No
SnapMirror Synchronous	No	No
SSDs	Yes.	Yes.
Storage efficiency features	Yes, beginning with ONTAP 9.9.1. Learn more about storage efficiency support.	Yes, beginning with ONTAP 9.9.1. Learn more about storage efficiency support.

FabricPool on SnapLock Enterprise aggregates

FabricPools are supported on SnapLock Enterprise aggregates beginning with ONTAP 9.8. However, your account team needs to open a product variance request documenting that you understand that FabricPool data tiered to a public or private cloud is no longer protected by SnapLock because a cloud admin can delete that data.

> Any data that FabricPool tiers to a public or private cloud is no longer protected by SnapLock because that data can be deleted by a cloud administrator.

FlexGroup volumes

SnapLock supports FlexGroup volumes beginning with ONTAP 9.11.1; however, the following features are not supported:

- Legal-hold
- Event-based retention
- SnapLock for SnapVault (supported beginning with ONTAP 9.12.1)

You should also be aware of the following behaviors:

- The volume compliance clock (VCC) of a FlexGroup volume is determined by the VCC of the root constituent. All non-root constituents will have their VCC closely synced to the root VCC.
- SnapLock configuration properties are set only on the FlexGroup as a whole. Individual constituents cannot have different configuration properties, such as default retention time and autocommit period.

LUN support

LUNs are supported in SnapLock volumes only in scenarios where snapshots created on a non-SnapLock volume are transferred to a SnapLock volume for protection as part of SnapLock vault relationship. LUNs are not supported in read/write SnapLock volumes. Tamperproof snapshots however are supported on both SnapMirror source volumes and destination volumes that contain LUNs.

MetroCluster support

SnapLock support in MetroCluster configurations differs between SnapLock Compliance mode and SnapLock Enterprise mode.

SnapLock Compliance

- Beginning with ONTAP 9.3, SnapLock Compliance is supported on unmirrored MetroCluster aggregates.
- Beginning with ONTAP 9.3, SnapLock Compliance is supported on mirrored aggregates, but only if the aggregate is used to host SnapLock audit log volumes.
- SVM-specific SnapLock configurations can be replicated to primary and secondary sites using MetroCluster.

SnapLock Enterprise

- SnapLock Enterprise aggregates are supported.
- Beginning with ONTAP 9.3, SnapLock Enterprise aggregates with privileged delete are supported.
- SVM-specific SnapLock configurations can be replicated to both sites using MetroCluster.

MetroCluster configurations and compliance clocks

MetroCluster configurations use two compliance clock mechanisms, the Volume Compliance Clock (VCC) and the System Compliance Clock (SCC). The VCC and SCC are available to all SnapLock configurations. When you create a new volume on a node, its VCC is initialized with the current value of the SCC on that node. After the volume is created, the volume and file retention time is always tracked with the VCC.

When a volume is replicated to another site, its VCC is also replicated. When a volume switchover occurs, from Site A to Site B, for example, the VCC continues to be updated on Site B while the SCC on Site A halts when Site A goes offline.

When Site A is brought back online and the volume switchback is performed, the Site A SCC clock restarts while the VCC of the volume continues to be updated. Because the VCC is continuously updated, regardless of switchover and switchback operations, the file retention times do not depend on SCC clocks and do not stretch.

Multi-admin verification (MAV) support

Beginning with ONTAP 9.13.1, a cluster administrator can explicitly enable multi-admin verification on a cluster to require quorum approval before some SnapLock operations are executed. When MAV is enabled, SnapLock volume properties such as default-retention-time, minimum-retention-time, maximum-retention-time, volume-append-mode, autocommit-period and privileged-delete will require quorum approval. Learn more about MAV.

Storage efficiency

Beginning with ONTAP 9.9.1, SnapLock supports storage efficiency features, such as data compaction, cross-volume-deduplication, and adaptive compression for SnapLock volumes and aggregates. For more information about storage efficiency, see ONTAP storage efficiency overview.

Encryption

ONTAP offers both software- and hardware-based encryption technologies for ensuring that data at rest cannot be read if the storage medium is repurposed, returned, misplaced, or stolen.

Disclaimer: NetApp cannot guarantee that SnapLock-protected WORM files on self-encrypting drives or volumes will be retrievable if the authentication key is lost or if the number of failed authentication attempts exceeds the specified limit and results in the drive being permanently locked. You are responsible for ensuring against authentication failures.

> Encrypted volumes are supported on SnapLock aggregates.

7-Mode Transition

You can migrate SnapLock volumes from 7-Mode to ONTAP by using the Copy-Based Transition (CBT) feature of the 7-Mode Transition Tool. The SnapLock mode of the destination volume, Compliance or Enterprise, must match the SnapLock mode of the source volume. You cannot use Copy-Free Transition (CFT) to migrate SnapLock volumes.

Configure SnapLock

Learn about configuring ONTAP SnapLock

Before you use SnapLock, you need to configure SnapLock by completing various tasks such as install the SnapLock license for each node that hosts an aggregate with a SnapLock volume, initialize the Compliance Clock, create a SnapLock aggregate for clusters running ONTAP releases earlier than ONTAP 9.10.1, create and mount a SnapLock volume, and more.

Initialize the ONTAP Compliance Clock

SnapLock uses the *volume Compliance Clock* to ensure against tampering that might alter the retention period for WORM files. You must first initialize the *system ComplianceClock* on each node that hosts a SnapLock aggregate.

Beginning with ONTAP 9.14.1, you can initialize or reinitialize the system Compliance Clock when there are no SnapLock volumes or no volumes with snapshot locking enabled. The ability to reinitialize enables system administrators to reset the system Compliance Clock in instances where it might have been incorrectly initialized or to correct clock drift on the system. In ONTAP 9.13.1 and earlier releases, once you initialize the Compliance Clock on a node, you cannot initialize it again.

Before you begin

To reinitialize the Compliance Clock:

- All nodes in the cluster must be in the healthy state.
- All volumes must be online.
- No volumes can be present the the recovery queue.
- No SnapLock volumes can be present.
- No volumes with snapshot locking enabled can be present.

General requirements for initializing the Compliance Clock:

- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.

About this task

The time on the system Compliance Clock is inherited by the *volume Compliance Clock*, the latter of which controls the retention period for WORM files on the volume. The volume Compliance Clock is initialized automatically when you create a new SnapLock volume.

> The initial setting of the system Compliance Clock is based on the current hardware system clock. For that reason, you should verify that the system time and time zone are correct before initializing the system Compliance Clock on each node. Once you initialize the system Compliance Clock on a node, you cannot initialize it again when SnapLock volumes or volumes with locking enabled are present.

Steps

You can use the ONTAP CLI to initialize the Compliance Clock or, beginning with ONTAP 9.12.1, you can use System Manager to initialize the Compliance Clock.

System Manager

1. Navigate to **Cluster > Overview**.
2. In the **Nodes** section, click **Initialize SnapLock Compliance Clock**.
3. To display the **Compliance Clock** column and to verify that the Compliance Clock is initialized, in the **Cluster > Overview > Nodes** section, click **Show/Hide** and select **SnapLock Compliance Clock**.

CLI

1. Initialize the system Compliance Clock:

   `snaplock compliance-clock initialize -node` *`node_name`*

   The following command initializes the system Compliance Clock on `node1`:

   ```
   cluster1::> snaplock compliance-clock initialize -node node1
   ```

   Learn more about `snaplock compliance-clock initialize` in the ONTAP command reference.

2. When prompted, confirm that the system clock is correct and that you want to initialize the Compliance Clock:

   ```
   Warning: You are about to initialize the secure ComplianceClock of
   the node "node1" to the current value of the node's system clock.
   This procedure can be performed only once on a given node, so you
   should ensure that the system time is set correctly before
   proceeding.

   The current node's system clock is: Mon Apr 25 06:04:10 GMT 2016

   Do you want to continue? (y|n): y
   ```

3. Repeat this procedure for each node that hosts a SnapLock aggregate.

Enable Compliance Clock resynchronization for an NTP-configured system

You can enable the SnapLock Compliance Clock synchronization feature when an NTP server is configured.

Before you begin

- This feature is available only at the advanced privilege level.
- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.
- This feature is available only for Cloud Volumes ONTAP, ONTAP Select, and VSIM platforms.

About this task

When the SnapLock secure clock daemon detects a skew beyond the threshold, ONTAP uses the system time to reset both the system and volume Compliance Clocks. A period of 24 hours is set as the skew threshold. This means that the system Compliance Clock is synchronized to the system clock only if the skew is more than a day old.

The SnapLock secure clock daemon detects a skew and changes the Compliance Clock to the system time. Any attempt at modifying the system time to force the Compliance Clock to synchronize to the system time fails, since the Compliance Clock synchronizes to the system time only if the system time is synchronized with the NTP time.

Steps

1. Enable the SnapLock Compliance Clock synchronization feature when an NTP server is configured:

   `snaplock compliance-clock ntp`

   The following command enables the system Compliance Clock synchronization feature:

   ```
   cluster1::*> snaplock compliance-clock ntp modify -is-sync-enabled true
   ```

   Learn more about `snaplock compliance-clock ntp modify` in the ONTAP command reference.

2. When prompted, confirm that the configured NTP servers are trusted and that the communications channel is secure to enable the feature:
3. Check that the feature is enabled:

   `snaplock compliance-clock ntp show`

   The following command checks that the system Compliance Clock synchronization feature is enabled:

   ```
   cluster1::*> snaplock compliance-clock ntp show

   Enable clock sync to NTP system time: true
   ```

   Learn more about `snaplock compliance-clock ntp show` in the ONTAP command reference.

Create an ONTAP SnapLock aggregate

You use the volume `-snaplock-type` option to specify a Compliance or Enterprise SnapLock volume type. For releases earlier than ONTAP 9.10.1, you must create a separate SnapLock aggregate. Beginning with ONTAP 9.10.1, SnapLock and non-SnapLock volumes can exist on the same aggregate; therefore, you are no longer required to create a separate SnapLock aggregate if you are using ONTAP 9.10.1.

Before you begin

- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node. This license in included in ONTAP One.
- The Compliance Clock on the node must be initialized.

- If you have partitioned the disks as “root”, “data1”, and “data2”, you must ensure that spare disks are available.

Upgrade considerations

When upgrading to ONTAP 9.10.1, existing SnapLock and non-SnapLock aggregates are upgraded to support the existence of both SnapLock and non-SnapLock volumes; however, the existing SnapLock volume attributes are not automatically updated. For example, data-compaction, cross-volume-dedupe, and cross-volume-background-dedupe fields remain unchanged. New SnapLock volumes created on existing aggregates have the same default values as non-SnapLock volumes, and the default values for new volumes and aggregates are platform dependent.

Revert considerations

If you need to revert to an ONTAP version earlier than 9.10.1, you must move all SnapLock Compliance, SnapLock Enterprise, and SnapLock volumes to their own SnapLock aggregates.

About this task

- You cannot create Compliance aggregates with the SyncMirror option.
- You can create mirrored Compliance aggregates in a MetroCluster configuration only if the aggregate is used to host SnapLock audit log volumes.

> In a MetroCluster configuration, SnapLock Enterprise is supported on mirrored and unmirrored aggregates. SnapLock Compliance is supported only on unmirrored aggregates.

Steps

1. Create a SnapLock aggregate:

```
storage aggregate create -aggregate <aggregate_name> -node <node_name>
-diskcount <number_of_disks> -snaplock-type <compliance|enterprise>
```

   The following command creates a SnapLock `Compliance` aggregate named `aggr1` with three disks on `node1`:

```
cluster1::> storage aggregate create -aggregate aggr1 -node node1
-diskcount 3 -snaplock-type compliance
```

   Learn more about `storage aggregate create` in the ONTAP command reference.

Create and mount ONTAP SnapLock volumes

You must create a SnapLock volume for the files or snapshots that you want to commit to the WORM state. Beginning with ONTAP 9.10.1, any volume you create, regardless of the aggregate type, is created by default as a non-SnapLock volume. You must use the `-snaplock-type` option to explicitly create a SnapLock volume by specifying either Compliance or Enterprise as the SnapLock type. By default, the SnapLock type is set to `non-snaplock`.

Before you begin

- The SnapLock aggregate must be online.
- You should verify that a SnapLock license is installed. If a SnapLock license is not installed on the node, you must install it. This license is included with ONTAP One. Prior to ONTAP One, the SnapLock license was included in the Security and Compliance bundle. The Security and Compliance bundle is no longer offered but is still valid. Although not currently required, existing customers can choose to upgrade to ONTAP One.
- The Compliance Clock on the node must be initialized.

About this task

With the proper SnapLock permissions, you can destroy or rename an Enterprise volume at any time. You cannot destroy a Compliance volume until the retention period has elapsed. You can never rename a Compliance volume.

You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume. The clone volume will be of the same SnapLock type as the parent volume.

> LUNs are not supported in SnapLock volumes. LUNs are supported in SnapLock volumes only in scenarios where snapshots created on a non-SnapLock volume are transferred to a SnapLock volume for protection as part of SnapLock vault relationship. LUNs are not supported in read/write SnapLock volumes. Tamperproof snapshots however are supported on both SnapMirror source volumes and destination volumes that contain LUNs.

Perform this task using ONTAP System Manager or the ONTAP CLI.

System Manager

Beginning with ONTAP 9.12.1, you can use System Manager to create a SnapLock volume.

Steps

1. Navigate to **Storage > Volumes** and click **Add**.
2. In the **Add Volume** window, click **More Options**.
3. Enter the new volume information, including the name and size of the volume.
4. Select **Enable SnapLock** and choose the SnapLock type, either Compliance or Enterprise.
5. In the **Auto-Commit Files** section, select **Modified** and enter the amount of time a file should remain unchanged before it is automatically committed. The minimum value is 5 minutes and the maximum value is 10 years.
6. In the **Data Retention** section, select the minimum and maximum retention period.
7. Select the default retention period.
8. Click **Save**.
9. Select the new volume in the **Volumes** page to verify the SnapLock settings.

CLI

1. Create a SnapLock volume:

```
volume create -vserver <SVM_name> -volume <volume_name> -aggregate
<aggregate_name> -snaplock-type <compliance|enterprise>
```

Learn more about `volume create` in the ONTAP command reference.
The following options are not available for SnapLock volumes: `-nvfail`, `-atime-update`, `-is-autobalance-eligible`, `-space-mgmt-try-first`, and `vmalign`.

The following command creates a SnapLock `Compliance` volume named `vol1` on `aggr1` on `vs1`:

```
cluster1::> volume create -vserver vs1 -volume vol1 -aggregate aggr1
-snaplock-type compliance
```

Mount a SnapLock volume

You can mount a SnapLock volume to a junction path in the SVM namespace for NAS client access.

Before you begin

The SnapLock volume must be online.

About this task

- You can mount a SnapLock volume only under the root of the SVM.
- You cannot mount a regular volume under a SnapLock volume.

Steps

1. Mount a SnapLock volume:

   `volume mount -vserver SVM_name -volume volume_name -junction-path path`

   Learn more about `volume mount` in the ONTAP command reference.

   The following command mounts a SnapLock volume named `vol1` to the junction path `/sales` in the `vs1` namespace:

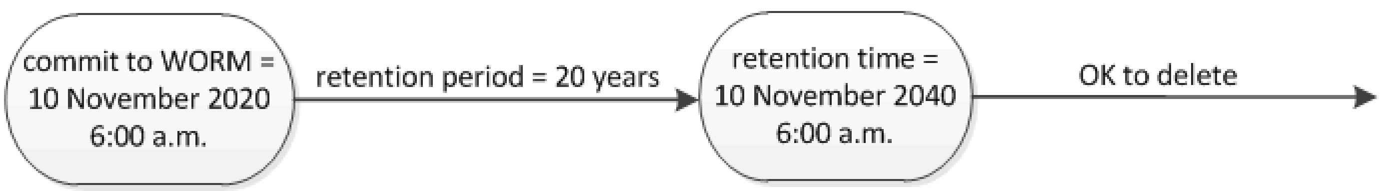
   ```
   cluster1::> volume mount -vserver vs1 -volume vol1 -junction-path /sales
   ```

Set the ONTAP SnapLock retention time

You can set the retention time for a file explicitly, or you can use the default retention period for the volume to derive the retention time. Unless you set the retention time explicitly, SnapLock uses the default retention period to calculate the retention time. You can also set file retention after an event.

About retention period and retention time

The *retention period* for a WORM file specifies the length of time the file must be retained after it is committed to the WORM state. The *retention time* for a WORM file is the time after which the file no longer needs to be retained. A retention period of 20 years for a file committed to the WORM state on 10 November 2020 6:00 a.m., for example, would yield a retention time of 10 November 2040 6:00 a.m.



> Beginning with ONTAP 9.10.1, you can set a retention time up to October 26, 3058 and a retention period up to 100 years. When you extend retention dates, older policies are converted automatically. In ONTAP 9.9.1 and earlier releases, unless you set the default retention period to infinite, the maximum supported retention time is January 19 2071 (GMT).

Important replication considerations

When establishing a SnapMirror relationship with a SnapLock source volume using a retention date later than January 19th 2071 (GMT), the destination cluster must be running ONTAP 9.10.1 or later or the SnapMirror transfer will fail.

Important revert considerations

ONTAP prevents you from reverting a cluster from ONTAP 9.10.1 to an earlier ONTAP version when there are any files with a retention period later than “January 19, 2071 8:44:07 AM”.

Understanding the retention periods

A SnapLock Compliance or Enterprise volume has four retention periods:

- Minimum retention period (`min`), with a default of 0

* Maximum retention period (`max`), with a default of 30 years
* Default retention period, with a default equal to `min` for both Compliance mode and Enterprise mode beginning with ONTAP 9.10.1. In ONTAP releases earlier than ONTAP 9.10.1, the default retention period depends on the mode:
    * For Compliance mode, the default is equal to `max`.
    * For Enterprise mode, the default is equal to `min`.
* Unspecified retention period.

  Beginning with ONTAP 9.8, you can set the retention period on files in a volume to `unspecified`, to enable the file to be retained until you set an absolute retention time. You can set a file with absolute retention time to unspecified retention and back to absolute retention as long as the new absolute retention time is later than the absolute time you previously set.

  Beginning with ONTAP 9.12.1, WORM files with the retention period set to `unspecified` are guaranteed to have a retention period set to the minimum retention period configured for the SnapLock volume. When you change the file retention period from `unspecified` to an absolute retention time, the new retention time specified must be greater than the minimum retention time already set on the file.

So, if you do not set the retention time explicitly before committing a Compliance-mode file to the WORM state, and you do not modify the defaults, the file will be retained for 30 years. Similarly, if you do not set the retention time explicitly before committing an Enterprise-mode file to the WORM state, and you do not modify the defaults, the file will be retained for 0 years, or, effectively, not at all.

Set the default retention period

You can use the `volume snaplock modify` command to set the default retention period for files on a SnapLock volume.

Before you begin

The SnapLock volume must be online.

About this task

The following table shows the possible values for the default retention period option:

> The default retention period must be greater than or equal to (>=) the minimum retention period and less than or equal to (<=) the maximum retention period.

Value	Unit	Notes
0 - 65535	seconds	
0 - 24	hours	
0 - 365	days	
0 - 12	months	

Value	Unit	Notes
0 - 100	years	Beginning with ONTAP 9.10.1. For earlier ONTAP releases, the value is 0 - 70.
max	-	Use the maximum retention period.
min	-	Use the minimum retention period.
infinite	-	Retain the files forever.
unspecified	-	Retain the files until an absolute retention period is set.

The values and ranges for the maximum and minimum retention periods are identical, except for `max` and `min`, which are not applicable. For more information about this task, see Set the retention time overview.

You can use the `volume snaplock show` command to view the retention period settings for the volume. Learn more about `volume snaplock show` in the ONTAP command reference.

After a file has been committed to the WORM state, you can extend but not shorten the retention period.

Steps

1. Set the default retention period for files on a SnapLock volume:

   `volume snaplock modify -vserver` *`SVM_name`* `-volume` *`volume_name`* `-default -retention-period` *`default_retention_period`* `-minimum-retention-period` *`min_retention_period`* `-maximum-retention-period` *`max_retention_period`*

   Learn more about `volume snaplock modify` in the ONTAP command reference.

   The following examples assume that the minimum and maximum retention periods have not been modified previously.

   The following command sets the default retention period for a Compliance or Enterprise volume to 20 days:

   ```
   cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default
   -retention-period 20days
   ```

   The following command sets the default retention period for a Compliance volume to 70 years:

   ```
   cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -maximum
   -retention-period 70years
   ```

The following command sets the default retention period for an Enterprise volume to 10 years:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default
-retention-period max -maximum-retention-period 10years
```

The following commands set the default retention period for an Enterprise volume to 10 days:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -minimum
-retention-period 10days
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default
-retention-period min
```

The following command sets the default retention period for a Compliance volume to infinite:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default
-retention-period infinite -maximum-retention-period infinite
```

Set the retention time for a file explicitly

You can set the retention time for a file explicitly by modifying its last access time. You can use any suitable command or program over NFS or CIFS to modify the last access time.

About this task

After a file has been committed to WORM, you can extend but not shorten the retention time. The retention time is stored in the `atime` field for the file.

> You cannot explicitly set the retention time of a file to `infinite`. That value is only available when you use the default retention period to calculate the retention time.

Steps

1. Use a suitable command or program to modify the last access time for the file whose retention time you want to set.

   In a UNIX shell, use the following command to set a retention time of 21 November 2020 6:00 a.m. on a file named `document.txt`:

   ```
   touch -a -t 202011210600 document.txt
   ```

   > You can use any suitable command or program to modify the last access time in Windows.

Set the file retention period after an event

Beginning with ONTAP 9.3, you can define how long a file is retained after an event occurs by using the SnapLock *Event Based Retention (EBR)* feature.

Before you begin

- You must be a SnapLock administrator to perform this task.

  Create a SnapLock administrator account

- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

The *event retention policy* defines the retention period for the file after the event occurs. The policy can be applied to a single file or all the files in a directory.

- If a file is not a WORM file, it will be committed to the WORM state for the retention period defined in the policy.
- If a file is a WORM file or a WORM appendable file, its retention period will be extended by the retention period defined in the policy.

You can use a Compliance-mode or Enterprise-mode volume.

> ⓘ EBR policies cannot be applied to files under a Legal Hold.

For advanced usage, see Compliant WORM Storage Using NetApp SnapLock.

Using EBR to extend the retention period of already existing WORM files
EBR is convenient when you want to extend the retention period of already existing WORM files. For example, it might be your firm's policy to retain employee W-4 records in unmodified form for three years after the employee changes a withholding election. Another company policy might require that W-4 records be retained for five years after the employee is terminated. In this situation, you could create an EBR policy with a five-year retention period. After the employee is terminated (the "event"), you would apply the EBR policy to the employee's W-4 record, causing its retention period to be extended. That will usually be easier than extending the retention period manually, particularly when a large number of files is involved.

Steps

1. Create an EBR policy:

   `snaplock event-retention policy create -vserver` *`SVM_name`* `-name` *`policy_name`* `-retention-period` *`retention_period`*

   The following command creates the EBR policy `employee_exit` on `vs1` with a retention period of ten years:

   ```
   cluster1::>snaplock event-retention policy create -vserver vs1 -name
   employee_exit -retention-period 10years
   ```

2. Apply an EBR policy:

   `snaplock event-retention apply -vserver` *`SVM_name`* `-name` *`policy_name`* `-volume` *`volume_name`* `-path` *`path_name`*

The following command applies the EBR policy `employee_exit` on `vs1` to all the files in the directory `d1`:

```
cluster1::>snaplock event-retention apply -vserver vs1 -name
employee_exit -volume vol1 -path /d1
```

- snaplock event-retention apply

Create an ONTAP SnapLock-protected audit log

If you are using ONTAP 9.9.1 or earlier, you must first create a SnapLock aggregate and then you must create a SnapLock-protected audit log before performing a privileged delete or SnapLock volume move. The audit log records the creation and deletion of SnapLock administrator accounts, modifications to the log volume, whether privileged delete is enabled, privileged delete operations, and SnapLock volume move operations.

Beginning with ONTAP 9.10.1, you no longer create a SnapLock aggregate. You must use the -snaplock-type option to explicitly create a SnapLock volume by specifying either Compliance or Enterprise as the SnapLock type.

Before you begin

If you are using ONTAP 9.9.1 or earlier, you must be a cluster administrator to create a SnapLock aggregate.

About this task

You cannot delete an audit log until the log file retention period has elapsed. You cannot modify an audit log even after the retention period has elapsed. This is true for both SnapLock Compliance and Enterprise modes.

> In ONTAP 9.4 and earlier, you cannot use a SnapLock Enterprise volume for audit logging. You must use a SnapLock Compliance volume. In ONTAP 9.5 and later, you can use either a SnapLock Enterprise volume or a SnapLock Compliance volume for audit logging. In all cases, the audit log volume must be mounted at the junction path `/snaplock_audit_log`. No other volume can use this junction path.

You can find the SnapLock audit logs in the `/snaplock_log` directory under the root of the audit log volume, in subdirectories named `privdel_log` (privileged delete operations) and `system_log` (everything else). Audit log file names contain the timestamp of the first logged operation, making it easy to search for records by the approximate time that operations were executed.

- You can use the `snaplock log file show` command to view the log files on the audit log volume.
- You can use the `snaplock log file archive` command to archive the current log file and create a new one, which is useful in cases where you need to record audit log information in a separate file.

Learn more about `snaplock log file show` and `snaplock log file archive` in the ONTAP command reference.

> A data protection volume cannot be used as a SnapLock audit log volume.

Steps

1. Create a SnapLock aggregate.

   Create a SnapLock aggregate

2. On the SVM that you want to configure for audit logging, create a SnapLock volume.

   Create a SnapLock volume

3. Configure the SVM for audit logging:

   `snaplock log create -vserver SVM_name -volume snaplock_volume_name -max-log -size size -retention-period default_retention_period`

   > The minimum default retention period for audit log files is six months. If the retention period of an affected file is longer than the retention period of the audit log, the retention period of the log inherits the retention period of the file. So, if the retention period for a file deleted using privileged delete is 10 months, and the retention period of the audit log is 8 months, the retention period of the log is extended to 10 months. For more information about retention time and default retention period, see Set the retention time.

   The following command configures `SVM1` for audit logging using the SnapLock volume `logVol`. The audit log has a maximum size of 20 GB and is retained for eight months.

   ```
   SVM1::> snaplock log create -vserver SVM1 -volume logVol -max-log-size
   20GB -retention-period 8months
   ```

   Learn more about `snaplock log create` in the ONTAP command reference.

4. On the SVM that you configured for audit logging, mount the SnapLock volume at the junction path `/snaplock_audit_log`.

   Mount a SnapLock volume

Verify ONTAP SnapLock settings

You can use the `volume file fingerprint start` and `volume file fingerprint dump` commands to view key information about files and volumes, including the file type (regular, WORM, or WORM appendable), the volume expiration date, and so forth.

Steps

1. Generate a file fingerprint:

   `volume file fingerprint start -vserver <SVM_name> -file <file_path>`

```
svm1::> volume file fingerprint start -vserver svm1 -file
/vol/sle/vol/f1
File fingerprint operation is queued. Run "volume file fingerprint show
-session-id 16842791" to view the fingerprint session status.
```

The command generates a session ID that you can use as input to the `volume file fingerprint dump` command.

> You can use the `volume file fingerprint show` command with the session ID to monitor the progress of the fingerprint operation. Make sure that the operation has completed before attempting to display the fingerprint.

2. Display the fingerprint for the file:

`volume file fingerprint dump -session-id <session_ID>`

```
svm1::> volume file fingerprint dump -session-id 33619976
        Vserver:svm1
        Session-ID:33619976
        Volume:slc_vol
        Path:/vol/slc_vol/f1

Manage WORM files

Manage WORM files with ONTAP SnapLock

You can manage WORM files in the following ways:

- Commit files to WORM
- Commit snapshots to WORM on a vault destination
- Mirror WORM files for disaster recovery
- Retain WORM files during litigation
- Delete WORM files

Commit files to WORM using ONTAP SnapLock

You can commit files to WORM (write once, read many) either manually or by committing them automatically. You can also create WORM appendable files.

Commit files to WORM manually

You commit a file to WORM manually by making the file read-only. You can use any suitable command or program over NFS or CIFS to change the read-write attribute of a file to read-only. You might choose to manually commit files if you want to ensure an application has finished writing to a file so that the file isn't committed prematurely or if there are scaling issues for the autocommit scanner because of a high number of volumes.

Before you begin

- The file you want to commit must reside on a SnapLock volume.
- The file must be writable.

About this task

The volume ComplianceClock time is written to the `ctime` field of the file when the command or program is executed. The ComplianceClock time determines when the retention time for the file has been reached.

Steps

1. Use a suitable command or program to change the read-write attribute of a file to read-only.

   In a UNIX shell, use the following command to make a file named `document.txt` read-only:

   ```
   chmod -w document.txt
   ```

   In a Windows shell, use the following command to make a file named `document.txt` read-only:

   ```
   attrib +r document.txt
   ```

Commit files to WORM automatically

The SnapLock autocommit feature enables you to commit files to WORM automatically. The autocommit feature commits a file to WORM state on a SnapLock volume if the file did not change for the autocommit-period
duration. The autocommit feature is disabled by default.

Before you begin

- The files you want to autocommit must reside on a SnapLock volume.
- The SnapLock volume must be online.
- The SnapLock volume must be a read-write volume.

> ⓘ The SnapLock autocommit feature scans through all of the files in the volume and commits a file if it meets the autocommit requirement. There might be a time interval between when the file is ready for autocommit and when it is actually committed by the SnapLock autocommit scanner. However, the file is still protected from modifications and deletion by the file system as soon as it is eligible for autocommit.

About this task

The *autocommit period* specifies the amount of time that files must remain unchanged before they are autocommitted. Changing a file before the autocommit period has elapsed restarts the autocommit period for the file.

The following table shows the possible values for the autocommit period:

Value	Unit	Notes
none	-	The default.
5 - 5256000	minutes	-
1 - 87600	hours	-
1 - 3650	days	-
1 - 120	months	-
1 - 10	years	-

The minimum value is 5 minutes and the maximum value is 10 years.

Steps

1. Autocommit files on a SnapLock volume to WORM:

   volume snaplock modify -vserver *SVM_name* -volume *volume_name* -autocommit -period *autocommit_period*

   Learn more about `volume snaplock modify` in the ONTAP command reference.

   The following command autocommits the files on volume `vol1` of SVM vs1, as long as the files remain unchanged for 5 hours:

   ```
   cluster1::>volume snaplock modify -vserver vs1 -volume vol1 -autocommit
   -period 5hours
   ```

Create a WORM appendable file

A WORM appendable file retains data written incrementally, like log entries. You can use any suitable command or program to create a WORM appendable file, or you can use the SnapLock *volume append mode* feature to create WORM appendable files by default.

Use a command or program to create a WORM appendable file

You can use any suitable command or program over NFS or CIFS to create a WORM appendable file. A WORM appendable file retains data written incrementally, like log entries. Data is appended to the file in 256 KB chunks. As each chunk is written, the previous chunk becomes WORM-protected. You cannot delete the file until the retention period has elapsed.

Before you begin

The WORM appendable file must reside on a SnapLock volume.

About this task

Data does not have to be written sequentially to the active 256 KB chunk. When data is written to byte n×256KB+1 of the file, the previous 256 KB segment becomes WORM-protected.

Any unordered writes beyond the current active 256 KB chunk will result in the active 256KB chunk being reset to the latest offset and will cause writes to older offsets to fail with a 'Read Only File System (ROFS)' error. The write offsets are dependent on the client application. A client that does not conform to the WORM append file write semantics can cause incorrect termination of the write contents. Therefore, it is recommended to either ensure that the client follows the offset restrictions for unordered writes, or to ensure synchronous writes by mounting the file system in synchronous mode.

Steps

1. Use a suitable command or program to create a zero-length file with the desired retention time.

   In a UNIX shell, use the following command to set a retention time of 21 November 2020 6:00 a.m. on a zero-length file named `document.txt`:

   ```
   touch -a -t 202011210600 document.txt
   ```

2. Use a suitable command or program to change the read-write attribute of the file to read-only.

   In a UNIX shell, use the following command to make a file named `document.txt` read-only:

   ```
   chmod 444 document.txt
   ```

3. Use a suitable command or program to change the read-write attribute of the file back to writable.

   > This step is not deemed a compliance risk because there is no data in the file.

   In a UNIX shell, use the following command to make a file named `document.txt` writable:

   ```
   chmod 777 document.txt
   ```

4. Use a suitable command or program to start writing data to the file.

   In a UNIX shell, use the following command to write data to `document.txt`:

   ```
   echo test data >> document.txt
   ```

   > Change the file permissions back to read-only when you no longer need to append data to the file.

Use volume append mode to create WORM appendable files

Beginning with ONTAP 9.3, you can use the SnapLock *volume append mode* (VAM) feature to create WORM appendable files by default. A WORM appendable file retains data written incrementally, like log entries. Data is appended to the file in 256 KB chunks. As each chunk is written, the previous chunk becomes WORM-protected. You cannot delete the file until the retention period has elapsed.

Before you begin

- The WORM appendable file must reside on a SnapLock volume.
- The SnapLock volume must be unmounted and empty of snapshots and user-created files.

About this task

Data does not have to be written sequentially to the active 256 KB chunk. When data is written to byte n×256KB+1 of the file, the previous 256 KB segment becomes WORM-protected.

If you specify an autocommit period for the volume, WORM appendable files that are not modified for a period greater than the autocommit period are committed to WORM.

> VAM is not supported on SnapLock audit log volumes.

Steps

1. Enable VAM:

   `volume snaplock modify -vserver` *`SVM_name`* `-volume` *`volume_name`* `-is-volume-append -mode-enabled true|false`

   Learn more about `volume snaplock modify` in the [ONTAP command reference](#).

   The following command enables VAM on volume `vol1` of SVM`vs1`:

   ```
   cluster1::>volume snaplock modify -vserver vs1 -volume vol1 -is-volume
   -append-mode-enabled true
   ```

2. Use a suitable command or program to create files with write permissions.

   The files are WORM-appendable by default.

Commit snapshots to WORM on an ONTAP vault destination

You can use SnapLock for SnapVault to WORM-protect snapshots on secondary storage. You perform all of the basic SnapLock tasks on the vault destination. The destination volume is automatically mounted read-only, so there is no need to explicitly commit the snapshots to WORM.

Before you begin

- If you want to use System Manager to configure the relationship, both the source and the destination clusters must be running ONTAP 9.15.1 or later.
- On the destination cluster:
  - Install the SnapLock license.
  - Initialize the Compliance Clock.
  - If you are using the CLI with an ONTAP release earlier than 9.10.1, create a SnapLock aggregate.
- The protection policy must be of type "vault".
- The source and destination aggregates must be 64-bit.

- The source volume cannot be a SnapLock volume.
- If you are using the ONTAP CLI, the source and destination volumes must be created in peered clusters and SVMs.

About this task

The source volume can use NetApp or non-NetApp storage.

> You cannot rename a snapshot that is committed to the WORM state.

You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.

> LUNs are not supported in SnapLock volumes. LUNs are supported in SnapLock volumes only in scenarios where snapshots created on a non-SnapLock volume are transferred to a SnapLock volume for protection as part of SnapLock vault relationship. LUNs are not supported in read/write SnapLock volumes. Tamperproof snapshots, however, are supported on both SnapMirror source volumes and destination volumes that contain LUNs.

Beginning with ONTAP 9.10.1, SnapLock and non-SnapLock volumes can exist on the same aggregate; therefore, you are no longer required to create a separate SnapLock aggregate if you are using ONTAP 9.10.1. You use the volume '-snaplock-type' option to specify a Compliance or Enterprise SnapLock volume type. In ONTAP releases earlier than ONTAP 9.10.1, the SnapLock mode, Compliance or Enterprise, is inherited from the aggregate. Version-flexible destination volumes are not supported. The language setting of the destination volume must match the language setting of the source volume.

A SnapLock volume that is a vault destination has a default retention period assigned to it. The value for this period is initially set to a minimum of 0 years for SnapLock Enterprise volumes and a maximum of 30 years for SnapLock Compliance volumes. Each NetApp snapshot is committed with this default retention period at first. The retention period can be extended later, if needed. For more information, see Set retention time overview.

Beginning with ONTAP 9.14.1, you can specify retention periods for specific SnapMirror labels in the SnapMirror policy of the SnapMirror relationship so that the replicated snapshots from the source to the destination volume are retained for the retention-period specified in the rule. If no retention period is specified, the default-retention-period of the destination volume is used.

Beginning with ONTAP 9.13.1, you can instantaneously restore a locked snapshot on the destination SnapLock volume of a SnapLock vault relationship by creating a FlexClone with the `snaplock-type` option set to `non-snaplock` and specifying the snapshot as the "parent-snapshot" when executing the volume clone creation operation. Learn more about creating a FlexClone volume with a SnapLock type.

For MetroCluster configurations, you should be aware of the following:

- You can create a SnapVault relationship only between sync-source SVMs, not between a sync-source SVM and a sync-destination SVM.
- You can create a SnapVault relationship from a volume on a sync-source SVM to a data-serving SVM.
- You can create a SnapVault relationship from a volume on a data-serving SVM to a DP volume on a sync-source SVM.

The following illustration shows the procedure for initializing a SnapLock vault relationship:

Steps

You can use the ONTAP CLI to create a SnapLock vault relationship or, beginning with ONTAP 9.15.1, you can use System Manager to create a SnapLock vault relationship.

System Manager

1. If the volume doesn't already exist, on the source cluster, navigate to **Storage > Volumes** and select **Add**.
2. In the **Add Volume** window, choose **More Options**.
3. Enter the volume name, size, export policy and share name.
4. Save your changes.
5. On the destination cluster, navigate to **Protection > Relationships**.
6. Above the **Source** column, select **Protect** and choose **Volumes** from the menu.
7. In the **Protect volumes** window, choose **Vault** as the protection policy.
8. In the **Source** section, select the cluster, storage VM, and volume you want to protect.
9. In the **Destination** section, under **Configuration details**, select **Lock destination snapshots**, and then choose **SnapLock for SnapVault** as the locking method. **Locking method** is not displayed if the policy type selected is not of type `vault`, if the SnapLock license is not installed, or if the Compliance Clock is not initialized.
10. If it is not already enabled, select **Initialize SnapLock Compliance Clock**.
11. Save your changes.

CLI

1. On the destination cluster, create a SnapLock destination volume of type `DP` that is either the same or greater in size than the source volume:

   ```
   volume create -vserver <SVM_name> -volume <volume_name> -aggregate
   <aggregate_name> -snaplock-type <compliance|enterprise> -type DP
   -size <size>
   ```

   The following command creates a 2GB SnapLock Compliance volume named `dstvolB` in `SVM2` on the aggregate `node01_aggr`:

   ```
   cluster2::> volume create -vserver SVM2 -volume dstvolB -aggregate
   node01_aggr -snaplock-type compliance -type DP -size 2GB
   ```

2. On the destination cluster, set the default retention period.
3. Create a new replication relationship between the non-SnapLock source and the new SnapLock destination you created.

   This example creates a new SnapMirror relationship with destination SnapLock volume `dstvolB` using a policy of `XDPDefault` to vault snapshots labeled daily and weekly on an hourly schedule:

   ```
   cluster2::> snapmirror create -source-path SVM1:srcvolA -destination
   -path SVM2:dstvolB -vserver SVM2 -policy XDPDefault -schedule hourly
   ```

Create a custom replication policy or a custom schedule if the available defaults are not suitable.

4. On the destination SVM, initialize the SnapVault relationship created:

```
snapmirror initialize -destination-path <destination_path>
```

The following command initializes the relationship between the source volume `srcvolA` on `SVM1` and the destination volume `dstvolB` on `SVM2`:

```
cluster2::> snapmirror initialize -destination-path SVM2:dstvolB
```

5. After the relationship is initialized and idle, use the `snapshot show` command on the destination to verify the SnapLock expiry time applied to the replicated snapshots.

This example lists the snapshots on volume `dstvolB` that have the SnapMirror label and the SnapLock expiration date:

```
cluster2::> snapshot show -vserver SVM2 -volume dstvolB -fields
snapmirror-label, snaplock-expiry-time
```

Mirror WORM files with ONTAP SnapMirror for disaster recovery

You can use SnapMirror to replicate WORM files to another geographic location for disaster recovery and other purposes. Both the source volume and destination volume must be configured for SnapLock, and both volumes must have the same SnapLock mode, Compliance or Enterprise. All key SnapLock properties of the volume and files are replicated.

Prerequisites

The source and destination volumes must be created in peered clusters with peered SVMs. For more information, see Cluster and SVM peering.

About this task

- Beginning with ONTAP 9.5, you can replicate WORM files with the XDP (extended data protection) type SnapMirror relationship rather than the DP (data protection) type relationship. XDP mode is ONTAP version-independent, and is able to differentiate files stored in the same block, making it much easier to resync replicated Compliance-mode volumes. For information on how to convert an existing DP-type relationship to an XDP-type relationship, see Data Protection.

* A resync operation on a DP type SnapMirror relationship fails for a Compliance-mode volume if SnapLock determines that it will result in a loss of data. If a resync operation fails, you can use the `volume clone create` command to make a clone of the destination volume. You can then resync the source volume with the clone.
* A SnapMirror relationship of a SnapLock volume only supports the `MirrorAllSnapshots` policy of type async-mirror. The retention period of a SnapLock volume is determined by the maximum retention period among all the WORM files that it holds. Because the destination is a DR copy of the source, the retention period of the destination SnapLock volume will be same as the source.
* A SnapMirror relationship of type XDP between SnapLock compliant volumes supports a resync after a break even if data on the destination has diverged from the source post the break.

  On a resync, when data divergence is detected between the source the destination beyond the common snapshot, a new snapshot is cut on the destination to capture this divergence. The new snapshot and the common snapshot are both locked with a retention time as follows:

  ◦ The volume expiry time of the destination
  ◦ If the volume expiry time is in the past or has not been set, then the snapshot is locked for a period of 30 days
  ◦ If the destination has legal-holds, the actual volume expiry period is masked and shows up as ‘indefinite’; however, the snapshot is locked for the duration of the actual volume expiry period.

If the destination volume has an expiry period that is later than the source, the destination expiry period is retained and will not be overwritten by the expiry period of the source volume post the resync.

If the destination has legal-holds placed on it that differ from the source, a resync is not allowed. The source and destination must have identical legal-holds or all legal-holds on the destination must be released before a resync is attempted.

A locked snapshot on the destination volume created to capture the divergent data can be copied to the source using the CLI by running the `snapmirror update -s snapshot` command. The snapshot once copied will continue to be locked at the source as well.

* SVM data protection relationships are not supported.
* Load-sharing data protection relationships are not supported.

The following illustration shows the procedure for initializing a SnapMirror relationship:

System Manager

Beginning with ONTAP 9.12.1, you can use System Manager to set up SnapMirror replication of WORM files.

Steps

1. Navigate to **Storage > Volumes**.
2. Click **Show/Hide** and select **SnapLock Type** to display the column in the **Volumes** window.
3. Locate a SnapLock volume.
4. Click ⋮ and select **Protect**.
5. Choose the destination cluster and the destination storage VM.
6. Click **More Options**.
7. Select **Show legacy policies** and select **DPDefault (legacy)**.
8. In the **Destination Configuration details** section, select **Override transfer schedule** and select **hourly**.
9. Click **Save**.
10. To the left of the source volume name, click the arrow to expand the volume details, and on the right side of the page,review the remote SnapMirror protection details.
11. On the remote cluster, navigate to **Protection Relationships**.
12. Locate the relationship and click the destination volume name to view the relationship details.
13. Verify that the destination volume SnapLock type and other SnapLock information.

CLI

1. Identify the destination cluster.
2. On the destination cluster, install the SnapLock license, initialize the Compliance Clock, and, if you are using an ONTAP release earlier than 9.10.1, create a SnapLock aggregate.
3. On the destination cluster, create a SnapLock destination volume of type `DP` that is either the same size as or greater in size than the source volume:

   volume create -vserver *SVM_name* -volume *volume_name* -aggregate *aggregate_name* -snaplock-type compliance|enterprise -type DP -size *size*

   > ⓘ Beginning with ONTAP 9.10.1, SnapLock and non-SnapLock volumes can exist on the same aggregate; therefore, you are no longer required to create a separate SnapLock aggregate if you are using ONTAP 9.10.1. You use the volume -snaplock-type option to specify a Compliance or Enterprise SnapLock volume type. In ONTAP releases earlier than ONTAP 9.10.1, the SnapLock mode—Compliance or Enterprise—is inherited from the aggregate. The language setting of the destination volume must match the language setting of the source volume.

   The following command creates a 2 GB SnapLock `Compliance` volume named `dstvolB` in `SVM2` on the aggregate `node01_aggr`:

```
cluster2::> volume create -vserver SVM2 -volume dstvolB -aggregate
node01_aggr -snaplock-type compliance -type DP -size 2GB
```

4. On the destination SVM, create a SnapMirror policy:

   `snapmirror policy create -vserver` *`SVM_name`* `-policy` *`policy_name`*

   The following command creates the SVM-wide policy `SVM1-mirror`:

   ```
   SVM2::> snapmirror policy create -vserver SVM2 -policy SVM1-mirror
   ```

5. On the destination SVM, create a SnapMirror schedule:

   `job schedule cron create -name` ***`schedule_name`*** **`-dayofweek`** ***`day_of_week`*** **`-hour`** ***`hour`*** **`-minute`** ***`minute`***

   The following command creates a SnapMirror schedule named `weekendcron`:

   ```
   SVM2::> job schedule cron create -name weekendcron -dayofweek
   "Saturday, Sunday" -hour 3 -minute 0
   ```

6. On the destination SVM, create a SnapMirror relationship:

   `snapmirror create -source-path` *`source_path`* `-destination-path` *`destination_path`* `-type XDP|DP -policy` *`policy_name`* `-schedule` *`schedule_name`*

   The following command creates a SnapMirror relationship between the source volume `srcvolA` on `SVM1` and the destination volume `dstvolB` on `SVM2`, and assigns the policy `SVM1-mirror` and the schedule `weekendcron`:

   ```
   SVM2::> snapmirror create -source-path SVM1:srcvolA -destination
   -path SVM2:dstvolB -type XDP -policy SVM1-mirror -schedule
   weekendcron
   ```

   The XDP type is available in ONTAP 9.5 and later. You must use the DP type in ONTAP 9.4 and earlier.

7. On the destination SVM, initialize the SnapMirror relationship:

   `snapmirror initialize -destination-path` *`destination_path`*

   The initialization process performs a *baseline transfer* to the destination volume. SnapMirror makes a snapshot of the source volume, then transfers the copy and all the data blocks that it references to the destination volume. It also transfers any other snapshots on the source volume to the destination volume.

The following command initializes the relationship between the source volume `srcvolA` on `SVM1` and the destination volume `dstvolB` on `SVM2`:

```
SVM2::> snapmirror initialize -destination-path SVM2:dstvolB
```

- snapmirror initialize
- snapmirror policy create

Retain WORM files during litigation using ONTAP SnapLock Legal Hold

Beginning with ONTAP 9.3, you can retain Compliance-mode WORM files for the duration of a litigation by using the *Legal Hold* feature.

Before you begin

- You must be a SnapLock administrator to perform this task.

  Create a SnapLock administrator account

- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

A file under a Legal Hold behaves like a WORM file with an indefinite retention period. It is your responsibility to specify when the Legal Hold period ends.

The number of files you can place under a Legal Hold depends on the space available on the volume.

Steps

1. Start a Legal Hold:

   ```
   snaplock legal-hold begin -litigation-name <litigation_name> -volume
   <volume_name> -path <path_name>
   ```

   The following command starts a Legal Hold for all the files in `vol1`:

   ```
   cluster1::>snaplock legal-hold begin -litigation-name litigation1
   -volume vol1 -path /
   ```

2. End a Legal Hold:

   ```
   snaplock legal-hold end -litigation-name <litigation_name> -volume
   ```

<volume_name> -path <path_name>

The following command ends a Legal Hold for all the files in `vol1`:

```
cluster1::>snaplock legal-hold end -litigation-name litigation1 -volume
vol1 -path /
```

Related information

- snaplock legal-hold begin
- snaplock legal-hold end

Delete WORM files with ONTAP SnapLock

You can delete Enterprise-mode WORM files during the retention period using the privileged delete feature.
Before you can use this feature, you must create a SnapLock administrator account and then using the account, enable the feature.

Create a SnapLock administrator account

You must have SnapLock administrator privileges to perform a privileged delete. These privileges are defined in the vsadmin-snaplock role. If you have not already been assigned that role, you can ask your cluster administrator to create an SVM administrator account with the SnapLock administrator role.

Before you begin

- You must be a cluster administrator to perform this task.
- You must have logged in on a secure connection (SSH, console, or ZAPI).

Steps

1. Create an SVM administrator account with the SnapLock administrator role:

   security login create -vserver *SVM_name* -user-or-group-name *user_or_group_name* -application *application* -authmethod *authentication_method* -role *role* -comment *comment*

   The following command enables the SVM administrator account `SnapLockAdmin` with the predefined `vsadmin-snaplock` role to access `SVM1` using a password:

   ```
   cluster1::> security login create -vserver SVM1 -user-or-group-name
   SnapLockAdmin -application ssh -authmethod password -role vsadmin-
   snaplock
   ```

   Learn more about `security login create` in the ONTAP command reference.

Enable the privileged delete feature

You must explicitly enable the privileged delete feature on the Enterprise volume that contains the WORM files you want to delete.

About this task

The value of the `-privileged-delete` option determines whether privileged delete is enabled. Possible values are `enabled`, `disabled`, and `permanently-disabled`.

> `permanently-disabled` is the terminal state. You cannot enable privileged delete on the volume after you set the state to `permanently-disabled`.

Steps

1. Enable privileged delete for a SnapLock Enterprise volume:

   `volume snaplock modify -vserver` *`SVM_name`* `-volume` *`volume_name`* `-privileged -delete disabled|enabled|permanently-disabled`

   The following command enables the privileged delete feature for the Enterprise volume `dataVol` on `SVM1`:

```
SVM1::> volume snaplock modify -vserver SVM1 -volume dataVol -privileged
-delete enabled
```

Delete Enterprise-mode WORM files

You can use the privileged delete feature to delete Enterprise-mode WORM files during the retention period.

Before you begin

- You must be a SnapLock administrator to perform this task.
- You must have created a SnapLock audit log and enabled the privileged delete feature on the Enterprise volume.

About this task

You cannot use a privileged delete operation to delete an expired WORM file. You can use the `volume file retention show` command to view the retention time of the WORM file that you want to delete.
Learn more about `volume file retention show` in the ONTAP command reference.

Step

1. Delete a WORM file on an Enterprise volume:

   `volume file privileged-delete -vserver` *`SVM_name`* `-file` *`file_path`*

   The following command deletes the file `/vol/dataVol/f1` on the SVM`SVM1`:

```
SVM1::> volume file privileged-delete -file /vol/dataVol/f1
```

Move an ONTAP SnapLock volume

Beginning with ONTAP 9.8, you can move a SnapLock volume to a destination aggregate of the same type, either Enterprise to Enterprise, or Compliance to Compliance. You must be assigned the SnapLock security role to move a SnapLock volume.

Create a SnapLock security administrator account

You must have SnapLock security administrator privileges to perform a SnapLock volume move. This privilege is granted to you with the *snaplock* role, introduced in ONTAP 9.8. If you have not already been assigned that role, you can ask your cluster administrator to create a SnapLock security user with this SnapLock security role.

Before you begin

- You must be a cluster administrator to perform this task.
- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

The snaplock role is associated with the admin SVM, unlike the vsadmin-snaplock role, which is associated with the data SVM.

Step

1. Create an SVM administrator account with the SnapLock administrator role:

   `security login create -vserver` ***`SVM_name`*** **`-user-or-group-name`** ***`user_or_group_name`*** **`-application`** ***`application`*** **`-authmethod`** ***`authentication_method`*** **`-role`** ***`role`*** **`-comment`** ***`comment`***

   The following command enables the SVM administrator account `SnapLockAdmin` with the predefined `snaplock` role to access admin SVM `cluster1` using a password:

   ```
   cluster1::> security login create -vserver cluster1 -user-or-group-name
   SnapLockAdmin -application ssh -authmethod password -role snaplock
   ```

   Learn more about `security login create` in the ONTAP command reference.

Move a SnapLock volume

You can use the `volume move` command to move a SnapLock volume to a destination aggregate.

Before you begin

- You must have created a SnapLock-protected audit log before performing SnapLock volume move.

  Create an audit log.

- If you are using a version of ONTAP earlier than ONTAP 9.10.1, the destination aggregate must be the same SnapLock type as the SnapLock volume you want to move; either Compliance to Compliance or Enterprise to Enterprise. Beginning with ONTAP 9.10.1, this restriction is removed and an aggregate can include both Compliance and Enterprise SnapLock volumes, as well as non-SnapLock volumes.

* You must be a user with the SnapLock security role.

Steps

1. Using a secure connection, log in to the ONTAP cluster management LIF:

   `ssh snaplock_user@cluster_mgmt_ip`

2. Move a SnapLock volume:

   `volume move start -vserver` ***`SVM_name`*** **`-volume`** ***`SnapLock_volume_name`*** **`-destination -aggregate`** ***`destination_aggregate_name`***

3. Check the status of the volume move operation:

   `volume move show -volume` ***`SnapLock_volume_name`*** **`-vserver`** ***`SVM_name`*** **`-fields volume,phase,vserver`**

Lock an ONTAP snapshot for protection against ransomware attacks

Beginning with ONTAP 9.12.1, you can lock a snapshot on a non-SnapLock volume to provide protection from ransomware attacks. Locking snapshots ensures that they can't be deleted accidentally or maliciously.

You use the SnapLock compliance clock feature to lock snapshots for a specified period so that they cannot be deleted until the expiration time is reached. Locking snapshots makes them tamperproof, protecting them from ransomware threats. You can use locked snapshots to recover data if a volume is compromised by a ransomware attack.

Beginning with ONTAP 9.14.1, snapshot locking supports long-term retention snapshots on SnapLock vault destinations and on non-SnapLock SnapMirror destination volumes. Snapshot locking is enabled by setting the retention period using SnapMirror policy rules associated with an existing policy label. The rule overrides the default retention period set on the volume. If there is no retention period associated with the SnapMirror label, the default retention period of the volume is used.

Tamperproof snapshot requirements and considerations

* If you are using the ONTAP CLI, all nodes in the cluster must be running ONTAP 9.12.1 or later. If you are using System Manager, all nodes must be running ONTAP 9.13.1 or later.
* The SnapLock license must be installed on the cluster. This license is included in ONTAP One.
* The compliance clock on the cluster must be initialized.
* When snapshot locking is enabled on a volume, you can upgrade the clusters to a version of ONTAP later than ONTAP 9.12.1; however, you cannot revert to an earlier version of ONTAP until all locked snapshots have reached their expiration date and are deleted and snapshot locking is disabled.
* When a snapshot is locked, the volume expiry time is set to the expiry time of the snapshot. If more than one snapshot is locked, the volume expiry time reflects the largest expiry time among all snapshots.
* The retention period for locked snapshots takes precedence over the snapshot keep count, which means the keep count limit is not honored if the snapshot retention period for locked snapshots has not expired.
* In a SnapMirror relationship, you can set a retention period on a mirror-vault policy rule, and the retention period is applied for snapshots replicated to the destination if the destination volume has snapshot locking enabled. The retention period takes precedence over keep count; for example, snapshots that have not passed their expiry will be retained even if the keep count is exceeded.

- You can rename a snapshot on a non-SnapLock volume. Snapshot rename operations on the primary volume of a SnapMirror relationship are reflected on the secondary volume only if the policy is MirrorAllSnapshots. For other policy types, the renamed snapshot is not propagated during updates.
- If you are using the ONTAP CLI, you can restore a locked snapshot with the `volume snapshot restore` command only if the locked snapshot is the most recent. If there are any unexpired snapshots later than the one being restored, the snapshot restore operation fails.

Features supported with tamperproof snapshots

- Cloud Volumes ONTAP
- FlexGroup volumes

  Snapshot locking is supported on FlexGroup volumes. Snapshot locking occurs only on the root constituent snapshot. Deleting the FlexGroup volume is allowed only if the root constituent expiration time has passed.

- FlexVol to FlexGroup conversion

  You can convert a FlexVol volume with locked snapshots to a FlexGroup volume. Snapshots remain locked after the conversion.

- SnapMirror asynchronous

  The compliance clock must be initialized on both the source and destination.

- SVM data mobility (used for migrating or relocating an SVM from a source cluster to a destination cluster)

  Supported beginning with ONTAP 9.14.1.

- SnapMirror policy rules using the `-schedule` parameter
- SVM DR

  The compliance clock must be initialized on both the source and destination.

- Volume clone and file clone

  You can create volume clones and file clones from a locked snapshot.

Unsupported features

The following features currently are not supported with tamperproof snapshots:

- Consistency groups
- FabricPool

  Tamperproof snapshots provide immutable protections that cannot be deleted. Because FabricPool requires the ability to delete data, FabricPool and snapshot locks cannot be enabled on the same volume.

- FlexCache volumes
- SMtape
- SnapMirror active sync
- SnapMirror synchronous

Enable snapshot locking when creating a volume

Beginning with ONTAP 9.12.1, you can enable snapshot locking when you create a new volume or when you modify an existing volume by using the `-snapshot-locking-enabled` option with the `volume create` and `volume modify` commands in the CLI. Beginning with ONTAP 9.13.1, you can use System Manager to enable snapshot locking.

System Manager

1. Navigate to **Storage > Volumes** and select **Add**.
2. In the **Add Volume** window, choose **More Options**.
3. Enter the volume name, size, export policy and share name.
4. Select **Enable Snapshot locking**. This selection is not displayed if the SnapLock license is not installed.
5. If it is not already enabled, select **Initialize SnapLock Compliance Clock**.
6. Save your changes.
7. In the **Volumes** window, select the volume you updated and choose **Overview**.
8. Verify that **SnapLock Snapshot Locking** displays as **Enabled**.

CLI

1. To create a new volume and enable snapshot locking, enter the following command:

   ```
   volume create -vserver <vserver_name> -volume <volume_name> -snapshot
   -locking-enabled true
   ```

   The following command enables snapshot locking on a new volume named vol1:

   ```
   > volume create -volume vol1 -aggregate aggr1 -size 100m -snapshot
   -locking-enabled true
   Warning: snapshot locking is being enabled on volume “vol1” in
   Vserver “vs1”. It cannot be disabled until all locked snapshots are
   past their expiry time. A volume with unexpired locked snapshots
   cannot be deleted.
   Do you want to continue: {yes|no}: y
   [Job 32] Job succeeded: Successful
   ```

Enable snapshot locking on an existing volume

Beginning with ONTAP 9.12.1, you can enable snapshot locking on an existing volume using the ONTAP CLI. Beginning with ONTAP 9.13.1, you can use System Manager to enable snapshot locking on an existing volume.

System Manager

1. Navigate to **Storage > Volumes**.
2. Select ⋮ and choose **Edit > Volume**.
3. In the **Edit Volume** window, locate the Snapshots (Local) Settings section and select **Enable snapshot locking**.

   This selection is not displayed if the SnapLock license is not installed.

4. If it is not already enabled, select **Initialize SnapLock Compliance Clock**.
5. Save your changes.
6. In the **Volumes** window, select the volume you updated and choose **Overview**.
7. Verify that **SnapLock snapshot locking** displays as **Enabled**.

CLI

1. To modify an existing volume to enable snapshot locking, enter the following command:

```
volume modify -vserver <vserver_name> -volume <volume_name> -snapshot
-locking-enabled true
```

Create a locked snapshot policy and apply retention

Beginning with ONTAP 9.12.1, you can create snapshot policies to apply a snapshot retention period and apply the policy to a volume to lock snapshots for the specified period. You can also lock a snapshot by manually setting a retention period. Beginning with ONTAP 9.13.1, you can use System Manager to create snapshot locking policies and apply them to a volume.

Create a snapshot locking policy

System Manager

1. Navigate to **Storage > Storage VMs** and select a storage VM.
2. Select **Settings**.
3. Locate **Snapshot Policies** and select →.
4. In the **Add Snapshot Policy** window, enter the policy name.
5. Select + Add .
6. Provide the snapshot schedule details, including the schedule name, maximum snapshots to keep, and SnapLock retention period.
7. In the **SnapLock Retention Period** column, enter the number of hours, days, months or years to retain the snapshots. For example, a snapshot policy with a retention period of 5 days locks a snapshot for 5 days from the time it is created, and it cannot be deleted during that time. The following retention period ranges are supported:
   - Years: 0 - 100
   - Months: 0 - 1200
   - Days: 0 - 36500
   - Hours: 0 - 24
8. Save your changes.

CLI

1. To create a snapshot policy, enter the following command:

   ```
   volume snapshot policy create -policy <policy_name> -enabled true
   -schedule1 <schedule1_name> -count1 <maximum snapshots> -retention-period1
   <retention_period>
   ```

   The following command creates a snapshot locking policy:

   ```
   cluster1> volume snapshot policy create -policy lock_policy -enabled
   true -schedule1 hourly -count1 24 -retention-period1 "1 days"
   ```

   A snapshot is not replaced if it is under active retention; that is, the retention count will not be honored if there are locked snapshots that have not yet expired.

Apply a locking policy to a volume

System Manager

1. Navigate to **Storage > Volumes**.
2. Select ⋮ and choose **Edit > Volume**.
3. In the **Edit Volume** window, select **Schedule snapshots**.
4. Select the locking snapshot policy from the list.
5. If snapshot locking is not already enabled, select **Enable snapshot locking**.
6. Save your changes.

CLI

1. To apply a snapshot locking policy to an existing volume, enter the following command:

```
volume modify -volume <volume_name> -vserver <vserver_name> -snapshot
-policy <policy_name>
```

Apply retention period during manual snapshot creation

You can apply a snapshot retention period when you manually create a snapshot. Snapshot locking must be enabled on the volume; otherwise, the retention period setting is ignored.

System Manager

1. Navigate to **Storage > Volumes** and select a volume.
2. In the volume details page, select the **Snapshots** tab.
3. Select + Add.
4. Enter the snapshot name and the SnapLock expiration time. You can select the calendar to choose the retention expiration date and time.
5. Save your changes.
6. In the **Volumes > Snapshots** page, select **Show/Hide** and choose **SnapLock Expiration Time** to display the **SnapLock Expiration Time** column and verify that the retention time is set.

CLI

1. To create a snapshot manually and apply a locking retention period, enter the following command:

```
volume snapshot create -volume <volume_name> -snapshot <snapshot name>
-snaplock-expiry-time <expiration_date_time>
```

The following command creates a new snapshot and sets the retention period:

```
cluster1> volume snapshot create -vserver vs1 -volume vol1 -snapshot
snap1 -snaplock-expiry-time "11/10/2022 09:00:00"
```

Apply retention period to an existing snapshot

System Manager

1. Navigate to **Storage > Volumes** and select a volume.
2. In the volume details page, select the **Snapshots** tab.
3. Select the snapshot, select ⋮, and choose **Modify SnapLock Expiration Time**. You can select the calendar to choose the retention expiration date and time.
4. Save your changes.
5. In the **Volumes > Snapshots** page, select **Show/Hide** and choose **SnapLock Expiration Time** to display the **SnapLock Expiration Time** column and verify that the retention time is set.

CLI

1. To manually apply a retention period to an existing snapshot, enter the following command:

   `volume snapshot modify-snaplock-expiry-time -volume <volume_name> -snapshot <snapshot name> -snaplock-expiry-time <expiration_date_time>`

   The following example applies a retention period to an existing snapshot:

   ```
   cluster1> volume snapshot modify-snaplock-expiry-time -volume vol1
   -snapshot snap2 -snaplock-expiry-time "11/10/2022 09:00:00"
   ```

Modify an existing policy to apply long-term retention

In a SnapMirror relationship, you can set a retention period on a mirror-vault policy rule, and the retention period is applied for snapshots replicated to the destination if the destination volume has snapshot locking enabled. The retention period takes precedence over keep count; for example, snapshots that have not passed their expiry will be retained even if the keep count is exceeded.

Beginning with ONTAP 9.14.1, you can modify an existing SnapMirror policy by adding a rule to set long-term retention of snapshots. The rule is used to override the default volume retention period on SnapLock vault destinations and on non-SnapLock SnapMirror destination volumes.

1. Add a rule to an existing SnapMirror policy:

   `snapmirror policy add-rule -vserver <SVM name> -policy <policy name> -snapmirror-label <label name> -keep <number of snapshots> -retention-period [<integer> days|months|years]`

   The following example creates a rule that applies a retention period of 6 months to the existing policy called "lockvault":

   ```
   snapmirror policy add-rule -vserver vs1 -policy lockvault -snapmirror
   -label test1 -keep 10 -retention-period "6 months"
   ```

   Learn more about `snapmirror policy add-rule` in the ONTAP command reference.

Consistency groups

Learn about ONTAP consistency groups

A consistency group is a collection of volumes that are managed as a single unit. In ONTAP, consistency groups provide easy management and a protection guarantee for an application workload spanning multiple volumes.

You can use consistency groups to simplify your storage management. Imagine you have an important database spanning twenty LUNs. You could manage the LUNs on an individual basis or treat the LUNs as a solitary dataset, organizing them into a single consistency group.

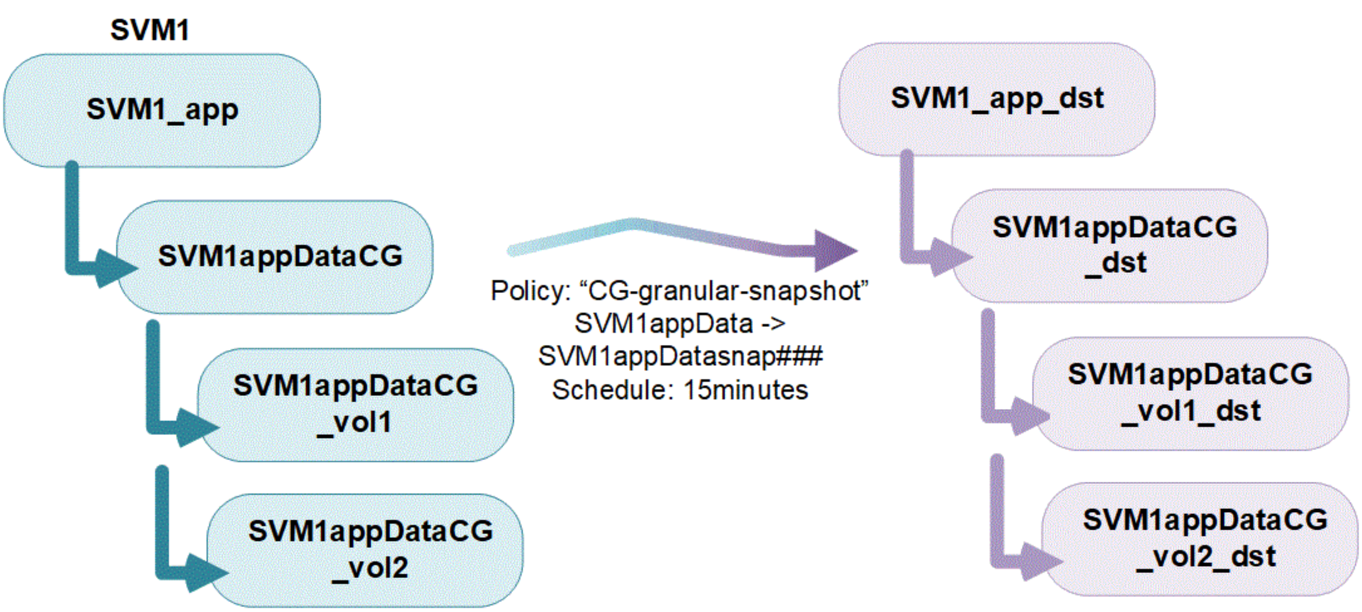
Consistency groups facilitate application workload management, providing easily configured local and remote protection policies and simultaneous crash-consistent or application-consistent snapshots of a collection of volumes at a point in time. Snapshots of a consistency groups enable an entire application workload to be restored.

Learn about consistency groups

Consistency groups support any FlexVol volume regardless of protocol (NAS, SAN, or NVMe) and can be managed through the ONTAP REST API or in System Manager under the **Storage > Consistency Groups** menu item. Beginning with ONTAP 9.14.1, consistency groups can be managed with the ONTAP CLI.

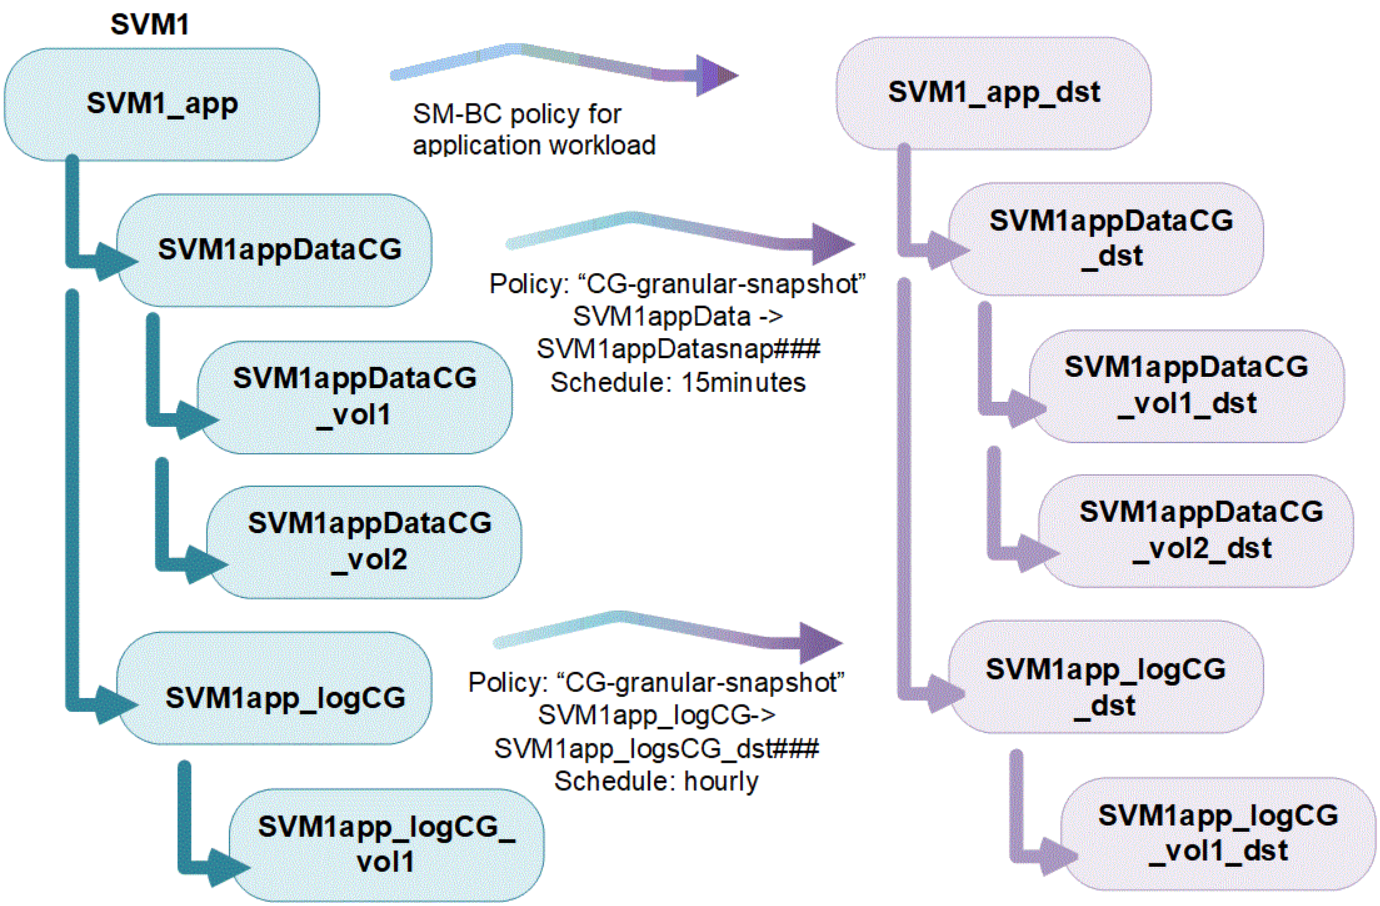
Consistency groups can exist as individual entities—as a collection of volumes—or in a hierarchical relationship, which consists of other consistency groups. Individual volumes can have their own volume-granular snapshot policy. In addition, there can be a consistency group-wide snapshot policy. The consistency group can only have one SnapMirror active sync relationship and shared SnapMirror policy, which can be used to recover the entire consistency group.

The following diagram illustrates how you might use an individual consistency group. The data for an application hosted on `SVM1` spans two volumes: `vol1` and `vol2`. A snapshot policy on the consistency group captures snapshots of the data every 15 minutes.



Larger application workloads might require multiple consistency groups. In these situations, you can create hierarchical consistency groups, where a single consistency group becomes the child components of a parent consistency group. The parent consistency group can include up to five child consistency groups. Like in individual consistency groups, a remote SnapMirror active sync protection policy can be applied to the entire configuration of consistency groups (parent and children) to recover the application workload.

In the following example, an application is hosted on `SVM1`. The administrator has created a parent consistency group, `SVM1_app`, which includes two child consistency groups: `SVM1appDataCG` for the data and `SVM1app_logCG` for the logs. Each child consistency group has its own snapshot policy. Snapshots of the volumes in `SVM1appDataCG` are taken every 15 minutes. Snapshots of `SVM1app_logCG` are taken hourly. The parent consistency group `SVM1_app` has an SnapMirror active sync policy which replicates the data to ensure continued service in the event of a disaster.



Beginning with ONTAP 9.12.1, consistency groups support cloning and modifying the members of the consistency by adding or removing volumes in both System Manager and the ONTAP REST API. Beginning with ONTAP 9.12.1, the ONTAP REST API also supports:

- Creating consistency groups with new NFS or SMB volumes or NVMe namespaces.
- Adding new or existing NFS or SMB volumes or NVMe namespaces to existing consistency groups.

For more information about the ONTAP REST API, refer to ONTAP REST API reference documentation.

Monitor consistency groups

Beginning with ONTAP 9.13.1, consistency groups offer real-time and historical capacity and performance monitoring, offering insights about the performance of applications and individual consistency groups.

Monitoring data is refreshed every five minutes and is maintained for up to one year. You can track metrics for:

- Performance: IOPS, latency, and throughput
- Capacity: Size, logical used, available

You can view monitoring data in the **Overview** tab of the consistency group menu in System Manager or by requesting it in the REST API. Beginning with ONTAP 9.14.1, you can view consistency group metrics with the CLI using the `consistency-group metrics show` command. Learn more about `consistency-group metrics show` in the ONTAP command reference.

> In ONTAP 9.13.1, you can only retrieve historical metrics using the REST API. Beginning with ONTAP 9.14.1, historical metrics are also available in System Manager.

Protect consistency groups

Consistency groups offer application-consistent protection, ensuring consistency of your data across multiple volumes or LIFs. When creating a snapshot of a consistency group, a "fence" is established on the consistency group. The fence initiates a queue for I/O until after the snapshot operation completes, ensuring point-in-time consistency of data across all entities in the consistency group. The fence can cause a transient spike in latency during snapshot creation operations, such as a scheduled snapshot policy or creating a snapshot with System Manager. Learn more about the context of REST API and CLI in the ONTAP REST API documentation and ONTAP command reference.

Consistency groups offer protection through:

- Snapshot policies
- SnapMirror active sync
- MetroCluster support (beginning with ONTAP 9.11.1)
- SnapMirror asynchronous (beginning with ONTAP 9.13.1)
- SVM disaster recovery (beginning with ONTAP 9.14.1)

Creating a consistency group does not automatically enable protection. Local and remote protection policies can be set when creating or after creating a consistency group.

To configure protection on a consistency group, see Protect a consistency group.

In order to use remote protection, you must meet the requirements for SnapMirror active sync.

> SnapMirror active sync relationships cannot be established on volumes mounted for NAS access.

Multi-admin verification support for consistency groups

Beginning with ONTAP 9.16.1, you can use multi-admin verification (MAV) with consistency groups to ensure that certain operations, such as creating, modifying, or deleting consistency groups, can be executed only after approvals from designated administrators. This prevents compromised, malicious, or inexperienced administrators from making undesirable changes to existing configurations.

Learn more

Consistency groups in MetroCluster configurations

Beginning with ONTAP 9.11.1, you can provision consistency groups with new volumes on a cluster within a

MetroCluster configuration. These volumes are provisioned on mirrored aggregates.

After they are provisioned, you can move volumes associated with consistency groups between mirrored and unmirrored aggregates. Therefore, volumes associated with consistency groups can be located on mirrored aggregates, unmirrored aggregates, or both. You can modify mirrored aggregates containing volumes associated with consistency groups to become unmirrored. Similarly, you can modify unmirrored aggregates containing volumes associated with consistency groups to enable mirroring.

Volumes and snapshots associated with consistency groups placed on mirrored aggregates are replicated to the remote site (site B). The contents of the volumes on site B provide a write-order guarantee for the consistency group, allowing you to recover from site B in the event of a disaster. You can access consistency group snapshots using consistency group with the REST API and System Manager on clusters running ONTAP 9.11.1 or later. Beginning with ONTAP 9.14.1, you can also access snapshots with the ONTAP CLI.

If some or all the volumes associated with a consistency group are located on unmirrored aggregates that are not currently accessible, GET or DELETE operations on the consistency group behave as if the local volumes or hosting aggregates are offline.

Consistency group configurations for replication

If site B is running ONTAP 9.10.1 or earlier, only the volumes associated with the consistency groups located on mirrored aggregates are replicated to site B. The consistency group configurations are only replicated to site B, if both sites are running ONTAP 9.11.1 or later. After site B is upgraded to ONTAP 9.11.1, data for consistency groups on site A that have all their associated volumes placed on mirrored aggregates are replicated to site B.

> It’s recommended you maintain at least 20% free space for mirrored aggregates for optimal storage performance and availability. Although the recommendation is 10% for non-mirrored aggregates, the additional 10% of space may be used by the filesystem to absorb incremental changes. Incremental changes increase space utilization for mirrored aggregates due to ONTAP’s copy-on-write snapshot-based architecture. Failure to adhere to these best practices may have a negative impact on performance.

Upgrade considerations

When upgrading to ONTAP 9.10.1 or later, consistency groups created with SnapMirror active sync (previously known as SnapMirror Business Continuity) in ONTAP 9.8 and 9.9.1 are automatically upgraded and become manageable under **Storage > Consistency Groups** in System Manager or the ONTAP REST API For more information about upgrading from ONTAP 9.8 or 9.9.1, see SnapMirror active sync upgrade and revert considerations.

Consistency group snapshots created in the REST API can be managed through System Manager’s Consistency Group interface and through consistency group REST API endpoints. Beginning with ONTAP 9.14.1, consistency group snapshots can also be managed with the ONTAP CLI.

> Snapshots created with the ONTAPI commands `cg-start` and `cg-commit` are not recognized as consistency group snapshots and thus cannot be managed through System Manager’s consistency group interface or the consistency group endpoints in the ONTAP REST API. Beginning with ONTAP 9.14.1, these snapshots can be mirrored to the destination volume if you are using a SnapMirror asynchronous policy. For more information, see Configure SnapMirror asynchronous.

Learn about ONTAP consistency group limits

When planning and managing your consistency groups, account for object limits at the scope of both the cluster and the parent or child consistency group.

Enforced limits

The following table captures limits for consistency groups. Separate limits apply for consistency groups using SnapMirror active sync. For more information, see SnapMirror active sync limits.

Limit	Scope	Minimum	Maximum
Number of consistency groups	Cluster	0	Same as maximum volume count in cluster*
Number of parent consistency groups	Cluster	0	Same as maximum volume count in cluster
Number of individual and parent consistency groups	Cluster	0	Same as maximum volume count in cluster

Number of volumes in a consistency group	Single consistency group	1 volume	80 volumes
Number of volumes in a consistency group with SnapMirror asynchronous	Single consistency group	1 volume	• In ONTAP 9.15.1 and later: 80 volumes • In ONTAP 9.13.1 and 9.14.1: 16 volumes
Number of volumes in the child of a parent consistency group	Parent consistency group	1 volume	80 volumes
Number of volumes in a child consistency group	Child consistency group	1 volume	80 volumes
Number of child consistency groups in a parent consistency group	Parent consistency group	1 consistency group	5 consistency groups
Number of SVM disaster recovery relationships where a consistency group exists (available beginning ONTAP 9.14.1)	Cluster	0	32

* A maximum of 50 consistency groups enabled with SnapMirror asynchronous can be hosted on a cluster.

Unenforced limits

The minimum supported snapshot schedule for consistency groups is 30 minutes. This is based on testing for FlexGroup volumes, which share the same Snapshot infrastructure as consistency groups.

Configure a single ONTAP consistency group

Consistency groups can be created with existing volumes or new LUNs or volumes (depending on the version of ONTAP). A volume or LUN can only be associated with one consistency group at a time.

About this task

- In ONTAP 9.10.1 through 9.11.1, modifying the member volumes of a consistency group after it is created is not supported.

  Beginning with ONTAP 9.12.1, you can modify the member volumes of a consistency group. For more information on this process, refer to Modify a consistency group.

- Beginning with ONTAP 9.17.1, you can select the NVMe protocol to map a host to an NVMe subsystem for VMware workloads in a SnapMirror active sync configuration.

Create a consistency group with new LUNs or volumes

In ONTAP 9.10.1 through 9.12.1, you can create a consistency group using new LUNs. Beginning with ONTAP 9.13.1, System Manager also supports creating a consistency group with new NVMe namespaces or new NAS volumes. (This is also supported in the ONTAP REST API beginning with ONTAP 9.12.1.)

System Manager (ONTAP 9.16.1 and earlier)

Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add** then select the protocol for your storage object.

   In ONTAP 9.10.1 through 9.12.1, the only option for a new storage object is **Using new LUNs**. Beginning with ONTAP 9.13.1, System Manager supports creating consistency groups with new NVMe namespaces and new NAS volumes.

3. Name the consistency group. Designate the number of volumes or LUNs and the capacity per volume or LUN.
   a. **Application Type**: If you are using ONTAP 9.12.1 or later, select an application type. If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in Application and component tags. If you plan to create a consistency group with a remote protection policy, you must use **Other**.
   b. For **New LUNs**: Select the host operating system and LUN format. Enter the host initiator information.
   c. For **New NAS volumes**: choose the appropriate export option (NFS or SMB/CIFS) based on the NAS configuration of your SVM.
   d. For **New NVMe namespaces**: Select the host operating system and NVMe subsystem.
4. To configure protection policies, add a child consistency group, or access permissions, select **More options**.
5. Select **Save**.
6. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the job completes. If you set a protection policy, you will know it has been applied when you see a green shield under look under the appropriate policy, remote or local.

System Manager (ONTAP 9.17.1 and later)

Steps

1. Select **Protection > Consistency groups**.
2. Select **+Add** then select the protocol for your storage object.
3. Name the consistency group. Designate the number of volumes or LUNs and the capacity per volume or LUN.
   Application Type: Select an application type. If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in Application and component tags. If you plan to create a consistency group with a remote protection policy, you must use **Other**.
   a. For **New LUNs**: Select the host operating system and LUN format. Enter the host initiator information.
   b. For **New NAS volumes**: choose the appropriate export option (NFS or SMB/CIFS) based on the NAS configuration of your SVM.
   c. For **New NVMe namespaces**: Select the host operating system and NVMe subsystem.
4. To configure protection policies, add a child consistency group, or access permissions, select **More options**.
5. Select **Save**.

6. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the job completes. If you set a protection policy, you will know it has been applied when you see a green shield under look under the appropriate policy, remote or local.

CLI

Beginning with ONTAP 9.14.1, you can create a new consistency group with new volumes using the ONTAP CLI. The specific parameters depends on whether the volumes are SAN, NVMe, or NFS.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Create a consistency group with NFS volumes

1. Create the consistency group:

```
consistency-group create -vserver <SVM_name> -consistency-group
<consistency-group-name> -volume-prefix <prefix_for_new_volume_names>
-volume-count <number> -size <size> -export-policy <policy_name>
```

Create a consistency group with SAN volumes

1. Create the consistency group:

```
consistency-group create -vserver <SVM_name> -consistency-group
<consistency-group-name> -lun <lun_name> -size <size> -lun-count <number>
-lun-os-type <LUN_operating_system_format> -igroup <igroup_name>
```

Create a consistency group with NVMe namespaces

1. Create the consistency group:

```
consistency-group create -vserver <SVM_name> -consistency-group
<consistency_group_name> -namespace <namespace_name> -volume-count <number>
-namespace-count <number> -size <size> -subsystem <subsystem_name>
```

Learn more about `consistency-group create` in the ONTAP command reference.

After you're done

1. Confirm your consistency group has been created using the `consistency-group show` command.

   Learn more about `consistency-group show` in the ONTAP command reference.

Create a consistency group with existing volumes

You can use existing volumes to create a consistency group.

System Manager (ONTAP 9.16.1 and earlier)

Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add** then **Using existing volumes**.
3. Name the consistency group and select the storage VM.
   a. **Application Type**: If you are using ONTAP 9.12.1 or later, select an application type. If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in Application and component tags. If the consistency group has a SnapMirror active sync relationship, you must use **Other**.

   > In versions of ONTAP earlier than ONTAP 9.15.1, SnapMirror active sync is referred to as SnapMirror Business Continuity.

4. Select the existing volumes to include. Only volumes that are not already part of a consistency group will be available for selection.

   > If creating a consistency group with existing volumes, the consistency group supports FlexVol volumes. Volumes with or SnapMirror synchronous or SnapMirror asynchronous relationships can be added to consistency groups, but they are not consistency group-aware. Consistency groups do not support S3 buckets or storage VMs with SVMDR relationships.

5. Select **Save**.
6. Confirm your consistency group has been created by returning to the main consistency group menu where it appears once the ONTAP job completes. If you have chosen a protection policy, confirm it was properly set by selecting your consistency group from the menu. If you set a protection policy, you know it has been applied when you see a green shield under look under the appropriate policy, remote or local.

CLI

Beginning with ONTAP 9.14.1, you can create a consistency group with existing volumes using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Steps

1. Issue the `consistency-group create` command. The `-volumes` parameter accepts a comma-separated list of volume names.

   ```
   consistency-group create -vserver <SVM_name> -consistency-group
   <consistency-group-name> -volume <volumes>
   ```

   Learn more about `consistency-group create` in the ONTAP command reference.

2. View your consistency group using the `consistency-group show` command.

Learn more about `consistency-group show` in the ONTAP command reference.

Next steps

- Protect a consistency group
- Modify a consistency group
- Clone a consistency group

Configure a hierarchical ONTAP consistency group

Hierarchical consistency groups enable you to manage large workloads spanning multiple volumes, creating a parent consistency group that serves as an umbrella for child consistency groups.

Hierarchical consistency groups have a parent that can include up to five individual consistency groups. Hierarchical consistency groups can support different local snapshot policies across consistency groups or individual volumes. If you use a remote protection policy, that will apply for the entire hierarchical consistency group (parent and children).

Beginning with ONTAP 9.13.1, you can modify the geometry of your consistency groups and move volumes between child consistency groups.

For object limits on consistency groups, see Object limits for consistency groups.

Create a hierarchical consistency group with new LUNs or volumes

When creating a hierarchical consistency group, you can populate it with new LUNs. Beginning with ONTAP 9.13.1, you can also use new NVMe namespaces and NAS volumes.

System Manager

Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add** then select the protocol for your storage object.

   In ONTAP 9.10.1 through 9.12.1, the only option for a new storage object is **Using new LUNs**. Beginning with ONTAP 9.13.1, System Manager supports creating consistency groups with new NVMe namespaces and new NAS volumes.

3. Name the consistency group. Designate the number of volumes or LUNs and the capacity per volume or LUN.
   a. **Application Type**: If you are using ONTAP 9.12.1 or later, select an application type. If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in Application and component tags. If you plan to use a remote protection policy, you must choose **Other**.
4. Select the host operating system and LUN format. Enter the host initiator information.
   a. For **New LUNs**: Select the host operating system and LUN format. Enter the host initiator information.
   b. For **New NAS volumes**: choose the appropriate export option (NFS or SMB/CIFS) based on the NAS configuration of your SVM.
   c. For **New NVMe namespaces**: Select the host operating system and NVMe subsystem.
5. To add a child consistency group, select **More options** then **+Add child consistency group**.
6. Select the performance level, the number of LUNs or volumes, and capacity per LUN or volume. Designate the appropriate export configurations or operating system information based on the protocol you are using.
7. Optionally, select a local snapshot policy and set the access permissions.
8. Repeat for up to five child consistency groups.
9. Select **Save**.
10. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you set a protection policy, look under the appropriate policy, remote or local, which should display a green shield with a checkmark in it.

CLI

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

When creating a hierarchical consistency group in the CLI with new volumes, you must create each child consistency group individually.

Step

1. Create the new consistency group using the `consistency-group create` command.

```
consistency-group create -vserver <SVM_name> -consistency-group
<consistency_group_name> -parent-consistency-group
```

```
<parent_consistency_group_name> -volume-prefix <volume_prefix> -volume
-count <number_of_volumes> -size <size>
```

2. When prompted by the CLI, confirm you want to create the new parent consistency group. Enter `y`.
3. Optionally, repeat step 1 to create more child consistency groups.

   Learn more about `consistency-group create` in the ONTAP command reference.

Create a hierarchical consistency group with existing volumes

You can organize existing volumes into a hierarchical consistency group.

System Manager

Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add** then **Using existing volumes**.
3. Select the storage VM.
4. Select the existing volumes to include. Only volumes that are not already part of a consistency group will be available for selection.
5. To add a child consistency group, select **+Add Child Consistency Group**. Create the necessary consistency groups, which will be named automatically.
   a. **Component Type**: If you are using ONTAP 9.12.1 or later, select a component type of "data", "logs", or "other". If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in Application and component tags. If you plan to use a remote protection policy, you must use **Other**.
6. Assign existing volumes to each consistency group.
7. Optionally, select a local snapshot policy.
8. Repeat for up to five child consistency groups.
9. Select **Save**.
10. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you have chosen a protection policy, confirm it was properly set by selecting your consistency group from the menu; under the appropriate policy type, you will see a green shield with a checkmark inside of it.

CLI

Beginning with ONTAP 9.14.1, you can create an hierarchical consistency group using the CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Steps

1. Provision a new parent consistency group and assign volumes to a new child consistency group:

```
consistency-group create -vserver <svm_name> -consistency-group
<child_consistency_group_name> -parent-consistency-group
<parent_consistency_group_name> -volumes <volume_names>
```

2. Enter `y` to confirm you want to create a new parent and child consistency group.

   Learn more about `consistency-group create` in the ONTAP command reference.

Next steps

- Modify the geometry of a consistency groups
- Modify a consistency group

* Protect a consistency group

Protect ONTAP consistency groups

Consistency groups offer easily managed local and remote protection for SAN, NAS, and NVMe applications that span multiple volumes.

Creating a consistency group does not automatically enable protection. Protection policies can be set at the time of creation or after creating your consistency group. You can protect consistency groups using:

* Local snapshots
* SnapMirror active sync (referred to as SnapMirror Business Continuity in versions of ONTAP before 9.15.1)
* MetroCluster (beginning 9.11.1)
* SnapMirror asynchronous (beginning 9.13.1)
* Asynchronous SVM disaster recovery (beginning 9.14.1)

If you are utilizing nested consistency groups, you can set different protection policies for the parent and child consistency groups.

Beginning with ONTAP 9.11.1, consistency groups offer two-phase consistency group snapshot creation. The two-phase snapshot operation executes a pre-check, ensuring the snapshot is captured successfully.

Recovery can occur for an entire consistency group, a single consistency group in a hierarchical configuration, or for individual volumes within the consistency group. Recovery can be achieved by selecting the consistency group you want to recover from, selecting the snapshot type, and then identifying the snapshot to base the restoration on. For more information about this process, see Restore a volume from an earlier snapshot.

Configure a local snapshot policy

Setting a local snapshot protection policy allows you to create a policy spanning all volumes in a consistency group.

About this task

The minimum supported snapshot schedule for consistency groups is 30 minutes. This is based on testing for FlexGroup volumes, which share the same Snapshot infrastructure as consistency groups.

System Manager

Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group you have created from the Consistency group menu.
3. At the top right of the overview page for the consistency group, select **Edit**.
4. Check the box next to **Schedule Snapshot copies (local)**.
5. Select a snapshot policy. To configure a new, custom policy, refer to Create a custom data protection policy.
6. Select **Save**.
7. Return to the consistency group overview menu. In the left column under **Snapshots (Local)**, the status will say protected next to .

CLI

Beginning with ONTAP 9.14.1, you can modify the protection policy of a consistency group using the CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Step

1. Issue the following command to set or modify the protection policy:

   If you are modifying the protection policy of a child consistency, you must identify the parent consistency group using the `-parent-consistency-group` *`parent_consistency_group_name`* parameter.

   ```
   consistency-group modify -vserver svm_name -consistency-group
   consistency_group_name -snapshot-policy policy_name
   ```

Create an on-demand snapshot

If you need to create a snapshot of your consistency group outside of a normally scheduled policy, you can create one on-demand.

System Manager

Steps

1. Navigate to **Storage** > **Consistency groups**.
2. Select the consistency group for which you want to create an on-demand snapshot.
3. Switch to the **Snapshot copies** tab then select **+Add**.
4. Provide a **Name** and a **SnapMirror Label**. In the dropdown menu for **Consistency**, select **Application consistent** or **Crash consistent**.
5. Select **Save**.

CLI

Beginning with ONTAP 9.14.1, you can create an on-demand snapshot of a consistency group using the CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Step

1. Create the snapshot:

   By default, the snapshot type is crash-consistent. You can modify the snapshot type with the optional `-type` parameter.

   ```
   consistency-group snapshot create -vserver svm_name -consistency-group
   consistency_group_name -snapshot snapshot_name
   ```

Create two-phase consistency group snapshots

Beginning with ONTAP 9.11.1, consistency groups support two-phase commits for consistency group (CG) snapshot creation, which execute a precheck before committing the snapshot. This feature is only available with the ONTAP REST API.

Two-phase CG snapshot creation is only available for snapshot creation, not provisioning consistency groups or restoring consistency groups.

A two-phase CG snapshot breaks the snapshot creation process into two phases:

1. In the first phase, the API executes prechecks and triggers snapshot creation. The first phase includes includes a timeout parameter, designating the amount of time for the snapshot to commit successfully.
2. If the request in phase one completes successfully, you can invoke the second phase within the designated interval from the first phase, committing the snapshot to the appropriate endpoint.

Before you begin

- To use two-phase CG snapshot creation, all nodes in the cluster must be running ONTAP 9.11.1 or later.
- Only one active invocation of a consistency group snapshot operation is supported on a consistency group instance at a time, whether it be a one-phase or two-phase. Attempting to invoke a snapshot operation while another one is in progress results in a failure.

- When you invoke the snapshot creation, you can set an optional timeout value of between 5 and 120 seconds. If no timeout value is provided, the operation times out at the default of 7 seconds. In the API, set the timeout value with the `action_timeout` parameter. In the CLI, use the `-timeout` flag.

Steps

You can complete a two-phase snapshot with the REST API or, beginning with ONTAP 9.14.1, the ONTAP CLI. This operation is not supported in System Manager.

> If you invoke the snapshot creation with the API, you must commit the snapshot with the API. If you invoke the snapshot creation with the CLI, you must commit the snapshot with the CLI. Mixing methods is not supported.

CLI

Beginning with ONTAP 9.14.1, you can create a two-phase snapshot using the CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Steps

1. Initiate the snapshot:

   `consistency-group snapshot start -vserver` *`svm_name`* `-consistency-group` *`consistency_group_name`* `-snapshot` *`snapshot_name`* `[-timeout` *`time_in_seconds`* `-write-fence {true|false}]`

2. Verify the snapshot was taken:

   `consistency-group snapshot show`

3. Commit the snapshot:

   `consistency-group snapshot commit` *`svm_name`* `-consistency-group` *`consistency_group_name`* `-snapshot` *`snapshot_name`*

API

1. Invoke the snapshot creation. Send a POST request to the consistency group endpoint using the `action=start` parameter.

   ```
   curl -k -X POST 'https://<IP_address>/application/consistency-
   groups/<cg-uuid>/snapshots?action=start&action_timeout=7' -H
   "accept: application/hal+json" -H "content-type: application/json"
   -d '
   {
     "name": "<snapshot_name>",
     "consistency_type": "crash",
     "comment": "<comment>",
     "snapmirror_label": "<SnapMirror_label>"
   }'
   ```

2. If the POST request succeeds, the output includes a snapshot uuid. Using that uuid, submit a PATCH request to commit the snapshot.

```
curl -k -X PATCH 'https://<IP_address>/application/consistency-
groups/<cg_uuid>/snapshots/<snapshot_id>?action=commit' -H "accept:
application/hal+json" -H "content-type: application/json"

For more information about the ONTAP REST API, see
link:https://docs.netapp.com/us-en/ontap-
automation/reference/api_reference.html[API reference^] or the
link:https://devnet.netapp.com/restapi.php[ONTAP REST API page^] at
the NetApp Developer Network for a complete list of API endpoints.
```

Set remote protection for a consistency group

Consistency groups offer remote protection through SnapMirror active sync and, beginning with ONTAP 9.13.1, SnapMirror asynchronous.

Configure protection with SnapMirror active sync

You can use SnapMirror active sync to ensure snapshots of consistency groups created on your consistency group are copied to the destination. To learn more about SnapMirror active sync or how to configure SnapMirror active sync using the CLI, see Configure protection for business continuity.

Before you begin

- SnapMirror active sync relationships cannot be established on volumes mounted for NAS access.
- The policy labels in the source and destination cluster must match.
- SnapMirror active sync will not replicate snapshots by default unless a rule with a SnapMirror label is added to the predefined `AutomatedFailOver` policy and the snapshots are created with that label.

  To learn more about this process, refer to Protect with SnapMirror active sync.
- Cascade deployments are not supported with SnapMirror active sync.
- Beginning with ONTAP 9.13.1, you can non-disruptively add volumes to a consistency group with an active SnapMirror active sync relationship. Any other changes to a consistency group require you to break the SnapMirror active sync relationship, modify the consistency group, then reestablish and resynchronize the relationship.

To configure SnapMirror active sync with the CLI, see Protect with SnapMirror active sync.

Steps for System Manager

1. Ensure you have met the prerequisites for using SnapMirror active sync.
2. Select **Storage > Consistency groups**.
3. Select the consistency group you have created from the Consistency group menu.
4. At the top right of the overview page, select **More** then **Protect**.
5. System Manager auto-fills source-side information. Select the appropriate cluster and storage VM for the destination. Select a protection policy. Ensure that **Initialize relationship** is checked.
6. Select **Save**.

7. The consistency group needs to initialize and synchronize. Confirm synchronization has completed successfully by returning to the **Consistency group** menu. The **SnapMirror (Remote)** status displays `Protected` next to .

Configure SnapMirror asynchronous

Beginning with ONTAP 9.13.1, you can configure SnapMirror asynchronous protection for a single consistency group. Beginning with ONTAP 9.14.1, you can use SnapMirror asynchronous to replicate volume-granular snapshots to the destination cluster using the consistency group relationship.

About this task

To replicate volume-granular snapshots, you must be running ONTAP 9.14.1 or later. For MirrorAndVault and Vault policies, the volume-granular snapshot policy's SnapMirror label must match the consistency group's SnapMirror policy rule. Volume-granular snapshots abide by the keep value of the consistency group's SnapMirror policy, which is calculated independently of the consistency group snapshots. For example, if you have a policy to keep two snapshots on the destination, you can have two volume-granular snapshots and two consistency group snapshots.

When resynchronizing the SnapMirror relationship with volume-granular snapshots, you can preserve volume-granular snapshots with the `-preserve` flag. Volume-granular snapshots newer than consistency group snapshots are preserved. If there is not a consistency group snapshot, no volume-granular snapshots can be transferred in the resync operation.

Before you begin

- SnapMirror asynchronous protection is only available for a single consistency group. It is not supported for hierarchical consistency groups. To convert a hierarchical consistency group into a single consistency group, see modify consistency group architecture.
- The policy labels in the source and destination cluster must match.
- You can non-disruptively add volumes to a consistency group with an active SnapMirror asynchronous relationship. Any other changes to a consistency group require you to break the SnapMirror relationship, modify the consistency group, then reestablish and resynchronize the relationship.
- Consistency groups enabled for protection with SnapMirror asynchronous have different limits. For more information, see Consistency group limits.
- If you have configured an SnapMirror asynchronous protection relationship for multiple individual volumes, you can convert those volumes into a consistency group while retaining the existing snapshots. To convert volumes successfully:
  - There must be a common snapshot of the volumes.
  - You must break the existing SnapMirror relationship, add the volumes to a single consistency group, then resynchronize the relationship using the following workflow.

Steps

1. From the destination cluster, select **Storage > Consistency groups**.
2. Select the consistency group you have created from the Consistency group menu.
3. At the top right of the overview page, select **More** then **Protect**.
4. System Manager auto-fills source-side information. Select the appropriate cluster and storage VM for the destination. Select a protection policy. Ensure that **Initialize relationship** is checked.

   When selecting an asynchronous policy, you have the option to **Override Transfer Schedule**.

> ⓘ The minimum supported schedule (recovery point objective, or RPO) for consistency groups with SnapMirror asynchronous is 30 minutes.

5. Select **Save**.
6. The consistency group needs to initialize and synchronize. Confirm synchronization has completed successfully by returning to the **Consistency group** menu. The **SnapMirror (Remote)** status displays `Protected` next to ✓.

Configure SVM disaster recovery

Beginning with ONTAP 9.14.1, SVM disaster recovery supports consistency groups, enabling you to mirror consistency group information from the source to the destination cluster.

If you are enabling SVM disaster recovery on an SVM that already contains a consistency group, following the SVM configuration workflows for System Manager or the ONTAP CLI.

If you are adding a consistency group to an SVM that is in an active and healthy SVM disaster recovery relationship, you must update the SVM disaster recovery relationship from the destination cluster. For more information, see Update a replication relationship manually. You must update the relationship any time you expand the consistency group.

Limitations

- SVM disaster recovery does not support hierarchical consistency groups.
- SVM disaster recovery does not support consistency groups protected with SnapMirror asynchronous. You must break the SnapMirror relationship before configuring SVM disaster recovery.
- Both clusters must be running ONTAP 9.14.1 or later.
- Fan-out relationships are not supported for SVM disaster recovery configurations that contain consistency groups.
- For other limits, see consistency group limits.

Visualize relationships

System Manager visualizes LUN maps under the **Protection > Relationships** menu. When you select a source relationship, System Manager displays a visualization of the source relationships. By selecting a volume, you can delve deeper into these relationships to see a list of the contained LUNs and the initiator group relationships. This information can be downloaded as an Excel workbook from the individual volume view; the download operation runs in the background.

Related information

- Clone a consistency group

- Create custom data protection policies
- Recover from snapshots
- Restore a volume from an earlier snapshot
- SnapMirror active sync overview
- ONTAP automation documentation
- SnapMirror asynchronous disaster recovery basics

Modify member volumes in an ONTAP consistency group

Beginning with ONTAP 9.12.1, you can modify a consistency group by removing volumes or adding volumes (expanding the consistency group). Beginning with ONTAP 9.13.1, you can move volumes between child consistency groups if they share a common parent.

Add volumes to a consistency group

Beginning with ONTAP 9.12.1, you can non-disruptively add volumes to a consistency group.

About this task

- You cannot add volumes associated with another consistency group.
- Consistency groups support NAS, SAN, and NVMe protocols.
- You can add up to 16 volumes at a time to a consistency group if the adjustments are within the overall consistency group limits.
- Beginning with ONTAP 9.13.1, you can non-disruptively add volumes to a consistency group with an active SnapMirror active sync or SnapMirror asynchronous protection policy.
- When you add volumes to a consistency group protected by SnapMirror active sync, the status of the SnapMirror active sync relationship status changes to "Expanding" until mirroring and protection are configured for the new volume. If a disaster occurs on the primary cluster before this process completes, the consistency group reverts back to its original composition as part of the failover operation.
- In ONTAP 9.12.1 and earlier, you *cannot* add volumes to a consistency group in an SnapMirror active sync relationship. You must first delete the SnapMirror active sync relationship, modify the consistency group, then restore protection with SnapMirror active sync.
- Beginning with ONTAP 9.12.1, the ONTAP REST API supports adding *new* or existing volumes to a consistency group. For more information about the ONTAP REST API, refer to ONTAP REST API reference documentation.

  Beginning with ONTAP 9.13.1, this functionality is supported in System Manager.

- When expanding a consistency group, snapshots of the consistency group captured before the modification will be considered partial. Any restore operation based on that snapshot will reflect the consistency group at the point-in-time of the snapshot.
- If you are using ONTAP 9.10.1 through 9.11.1, you cannot modify a consistency group. To change the configuration of a consistency group in ONTAP 9.10.1 or 9.11.1, you must delete the consistency group, then create a new consistency group with the volumes you want to include.
- Beginning with ONTAP 9.14.1, you can replicate volume-granular snapshots to the destination cluster when using SnapMirror asynchronous. When expanding a consistency group using SnapMirror asynchronous, volume-granular snapshots are only replicated after expanding the consistency group when the SnapMirror policy is MirrorAll or MirrorAndVault. Only volume-granular snapshots newer than the baseline consistency group snapshot are replicated.
- If you add volumes to a consistency group in an SVM disaster recovery relationship (supported beginning with ONTAP 9.14.1), you must update the SVM disaster recovery relationship from the destination cluster after expanding the consistency group. For more information, see Update a replication relationship manually.
- If you are using NVMe with ONTAP 9.17.1, you cannot modify a consistency group.

Example 31. Steps

System Manager

Beginning with ONTAP 9.12.1, you can perform this operation with System Manager.

1. Select **Storage > Consistency groups**.
2. Select the consistency group that you want to modify.
3. If you are modifying a single consistency group, at the top of the **Volumes** menu, select **More** and then **Expand** to add a volume.

   If you are modifying a child consistency group, identify the parent consistency group you want to modify. Select the **>** button to view the child consistency groups, then select ⋮ next to the name of the child consistency group you want to modify. From that menu, select **Expand**.
4. Select up to 16 volumes to add to the consistency group.
5. Select **Save**. When the operation completes, view the newly added volumes in the consistency group's **Volumes** menu.

CLI

Beginning with ONTAP 9.14.1, you can add volumes to a consistency group using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Add existing volumes

1. Issue the following command. The `-volumes` parameter accepts a comma-separated list of volumes.

   > Only include the `-parent-consistency-group` parameter if the consistency group is in an hierarchical relationship.

   ```
   consistency-group volume add -vserver svm_name -consistency-group
   consistency_group_name -parent-consistency-group parent_consistency_group
   -volume volumes
   ```

Add new volumes

The procedure to add new volumes depends on the protocol you are using.

> Only include the `-parent-consistency-group` parameter if the consistency group is in a hierarchical relationship.

- To add new volumes without exporting them:

  ```
  consistency-group volume create -vserver SVM_name -consistency-group
  child_consistency_group -parent-consistency-group existingParentCg -volume
  volume_name -size size
  ```

- To add new NFS volumes:

```
consistency-group volume create -vserver SVM_name -consistency-group
consistency-group-name -volume volume-prefix -volume-count number -size
size -export-policy policy_name
```

• To add new SAN volumes:

```
consistency-group volume create -vserver SVM_name -consistency-group
consistency-group-name -lun lun_name -size size -lun-count number -igroup
igroup_name
```

• To add new NVMe namespaces:

```
consistency-group volume create -vserver SVM_name -consistency-group
consistency_group_name -namespace namespace_name -volume-count number
-namespace-count number -size size -subsystem subsystem_name
```

Remove volumes from a consistency group

Volumes removed from a consistency group are not deleted. They remain active in the cluster.

About this task

- You cannot remove volumes from a consistency group in a SnapMirror active sync or SVM disaster recovery relationship. You must first delete the SnapMirror active sync relationship to modify the consistency group and then reestablish the relationship.
- If a consistency group has no volumes in it following the remove operation, the consistency group will be deleted.
- When a volume is removed from a consistency group, existing snapshots of the consistency group remain but are considered invalid. The existing snapshots cannot be used to restore the contents of the consistency group. Volume-granular snapshots remain valid.
- If you delete a volume from the cluster, it is automatically removed from the consistency group.
- To change the configuration of a consistency group in ONTAP 9.10.1 or 9.11.1, you must delete the consistency group then create a new consistency group with the desired member volumes.
- Deleting a volume from the cluster will automatically remove it from the consistency group.

System Manager

Beginning with ONTAP 9.12.1, you can perform this operation with System Manager.

Steps

1. Select **Storage > Consistency groups**.
2. Select the single or child consistency group that you want to modify.
3. In the **Volumes** menu, select the checkboxes next to the individual volumes you want to remove from the consistency group.
4. Select **Remove volumes from the consistency group**.
5. Confirm that you understand removing the volumes will cause all snapshots of the consistency group to become invalid and select **Remove**.

CLI

Beginning with ONTAP 9.14.1, you can remove volumes from a consistency group using the CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Step

1. Remove the volumes. The `-volumes` parameter accepts a comma-separated list of volumes.

   Only include the `-parent-consistency-group` parameter if the consistency group is in an hierarchical relationship.

   ```
   consistency-group volume remove -vserver SVM_name -consistency-group
   consistency_group_name -parent-consistency-group
   parent_consistency_group_name -volume volumes
   ```

Move volumes between consistency groups

Beginning with ONTAP 9.13.1, you can move volumes between child consistency groups that share a parent.

About this task

- You can only move volumes between consistency groups nested under the same parent consistency group.
- Existing consistency group snapshots become invalid and no longer accessible as consistency group snapshots. Individual volume snapshots remain valid.
- Snapshots of the parent consistency group remain valid.
- If you move all volumes out of a child consistency group, that consistency group will be deleted.
- Modifications to a consistency group must abide by consistency group limits.

System Manager

Beginning with ONTAP 9.12.1, you can perform this operation with System Manager.

Steps

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group that contains the volumes you want to move. Find the child consistency group and then expand the **Volumes** menu. Select the volumes you want to move.
3. Select **Move**.
4. Choose whether you want to move the volumes to a new consistency group or an existing group.
   a. To move to an existing consistency group, select **Existing child consistency group** then choose the consistency group's name from the dropdown menu.
   b. To move to a new consistency group, select **New child consistency group**. Enter a name for the new child consistency group and select a component type.
5. Select **Move**.

CLI

Beginning with ONTAP 9.14.1, you can move volumes between consistency groups using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Move volumes to a new child consistency group

1. The following command creates a new child consistency group that contains the designated volumes.

   When you create the new consistency group, you can designate new snapshot, QoS, and tiering policies.

   ```
   consistency-group volume reassign -vserver SVM_name -consistency-group
   source_child_consistency_group -parent-consistency-group
   parent_consistency_group -volume volumes -new-consistency-group
   consistency_group_name [-snapshot-policy policy -qos-policy policy -tiering
   -policy policy]
   ```

Move volumes to an existing child consistency group

1. Reassign the volumes. The `-volumes` parameter accepts a comma-separated list of volume names.

   ```
   consistency-group volume reassign -vserver SVM_name -consistency-group
   source_child_consistency_group -parent-consistency-group
   parent_consistency_group -volume volumes -to-consistency-group
   target_consistency_group
   ```

Related information

- Consistency group limits

* Clone a consistency group

Modify ONTAP consistency group geometry

Beginning with ONTAP 9.13.1, you can modify the geometry of a consistency group. Modifying the geometry of a consistency group enables you to alter the configuration of child or parent consistency groups without disruption to ongoing IO operations.

Modifying consistency group geometry has an impact on existing snapshots of the consistency group. For details, refer to the specific modification to geometry you want to perform.

> You cannot modify the geometry of a consistency group that is configured with a remote protection policy. You must first break the protection relationship, modify the geometry, then restore remote protection.

Add a new child consistency group

Beginning with ONTAP 9.13.1, you can add a new child consistency group to an existing parent consistency group.

About this task

* A parent consistency group can contain a maximum of five child consistency groups. See consistency group limits for other limits.
* You cannot add a child consistency group to a single consistency group. You must first promote the consistency group, then you can add a child consistency group.
* Existing snapshots of the consistency group captured before the expand operation will be considered partial. Any restore operation based on that snapshot will reflect the consistency group at the point-in-time of the snapshot.

Example 32. Steps

System Manager

Beginning with ONTAP 9.13.1, you can perform this operation with System Manager.

Add a new child consistency group

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group you want to which you want to add a child consistency group.
3. Next to the parent consistency group's name, select **More** then **Add new child consistency group**.
4. Enter a name for your consistency group.
5. Choose whether you would like to add new or existing volumes.
   a. If you are adding existing volumes, select **Existing volumes** then choose the volumes from the dropdown menu.
   b. If you are adding new volumes, select **New volumes** then designate the number of volumes and their size.
6. Select **Add**.

CLI

Beginning with ONTAP 9.14.1, you can add a child consistency group using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Add a child consistency group with new volumes

1. Create the new consistency group. Provide values for the consistency group name, volume prefix, number of volumes, volume size, storage service, and export policy name:

```
consistency-group create -vserver SVM_name -consistency-group
consistency_group -parent-consistency-group parent_consistency_group
-volume-prefix prefix -volume-count number -size size -storage-service
service -export-policy policy_name
```

Add a child consistency group with existing volumes

1. Create the new consistency group. The `volumes` parameter accepts a comma-separated list of volume names.

```
consistency-group create -vserver SVM_name -consistency-group
new_consistency_group -parent-consistency-group parent_consistency_group
-volumes volume
```

Detach a child consistency group

Beginning with ONTAP 9.13.1, you can remove a child consistency group from its parent, converting it into an individual consistency group.

About this task

- Detaching a child consistency group causes the parent consistency group's snapshots to become invalid and inaccessible. Volume granular snapshots remain valid.
- Existing snapshots of the individual consistency group remain valid.
- This operation will fail if there is an existing single consistency group that has the same name as the child consistency group you intend to detach. If you encounter this scenario, you must rename the consistency group when you detach it.

Example 33. Steps

System Manager

Beginning with ONTAP 9.13.1, you can perform this operation with System Manager.

Detach a child consistency group

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group that contains the child you want to detach.
3. Next to the child consistency group you want to detach, select **More** then **Detach from parent**.
4. Optionally, rename the consistency group and select an application type.
5. Select **Detach**.

CLI

Beginning with ONTAP 9.14.1, you can detach a child consistency group using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Detach a child consistency group

1. Detach the consistency group. Optionally, rename the detached consistency group with the `-new -name` parameter.

```
consistency-group detach -vserver SVM_name -consistency-group
child_consistency_group -parent-consistency-group parent_consistency_group
[-new-name new_name]
```

Move an existing single consistency group under a parent consistency group

Beginning with ONTAP 9.13.1, you can convert an existing single consistency group to a child consistency group. You can either move the consistency group under an existing parent consistency group or create a new parent consistency group during the move operation.

About this task

- The parent consistency group must have four or fewer children. A parent consistency group can contain a maximum of five child consistency groups. See consistency group limits for other limits.
- Existing snapshots of the *parent* consistency group captured before this operation are considered partial. Any restore operation based on one of those snapshots reflects the consistency group at the point-in-time

of the snapshot.

- Existing consistency group snapshots of the single consistency group remain valid.

Example 34. Steps

System Manager

Beginning with ONTAP 9.13.1, you can perform this operation with System Manager.

Move an existing single consistency group under a parent consistency group

1. Select **Storage > Consistency groups**.
2. Select the consistency group you want to convert.
3. Select **More** then **Move under different consistency group**.
4. Optionally, enter a new name for the consistency group and select a component type. By default, the component type will be Other.
5. Choose if you want to migrate to an existing parent consistency group or create a new parent consistency group:
   a. To migrate to an existing parent consistency group, select **Existing consistency group** then choose the consistency group from the dropdown menu.
   b. To create a new parent consistency group, select **New consistency group** then provide a name for the new consistency group.
6. Select **Move**.

CLI

Beginning with ONTAP 9.14.1, you can move a single consistency group under a parent consistency group using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Move a consistency group under a new parent consistency group

1. Create the new parent consistency group. The `-consistency-groups` parameter will migrate any existing consistency groups to the new parent.

```
consistency-group attach -vserver svm_name -consistency-group
parent_consistency_group -consistency-groups child_consistency_group
```

Move a consistency group under an existing consistency group

1. Move the consistency group:

```
consistency-group add -vserver SVM_name -consistency-group
consistency_group -parent-consistency-group parent_consistency_group
```

Promote a child consistency group

Beginning with ONTAP 9.13.1, you can promote a single consistency group to a parent consistency group. When you promote the single consistency group to a parent, you also create a new child consistency group that inherits all of the volumes in the original, single consistency group.

About this task

- If you want to convert a child consistency group to a parent consistency group, you must first detach the child consistency group then follow this procedure.
- Existing snapshots of the consistency group remain valid after you promote the consistency group.

System Manager

Beginning with ONTAP 9.13.1, you can perform this operation with System Manager.

Promote a child consistency group

1. Select **Storage > Consistency groups**.
2. Select the consistency group you want to promote.
3. Select **More** then **Promote to parent consistency group**.
4. Enter a **Name** and select a **Component type** for the child consistency group.
5. Select **Promote**.

CLI

Beginning with ONTAP 9.14.1, you can move a single consistency group under a parent consistency group using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Promote a child consistency group

1. Promote the consistency group. This command will create one parent and one child consistency group.

```
consistency-group promote -vserver SVM_name -consistency-group
existing_consistency_group -new-name new_child_consistency_group
```

Demote a parent to a single consistency group

Beginning with ONTAP 9.13.1, you can demote a parent consistency group to a single consistency group. Demoting the parent flattens the hierarchy of the consistency group, removing all associated child consistency groups. All volumes in the consistency group will remain under the new, single consistency group.

About this task

- Existing snapshots of the *parent* consistency group remain valid after you demote it to a single consistency. Existing snapshots of any of the associated *child* consistency groups of that parent become invalid upon demotion. The individual volume snapshots within the child consistency group continue to be accessible as volume-granular snapshots.

Example 35. Steps

System Manager

Beginning with ONTAP 9.13.1, you can perform this operation with System Manager.

Demote a consistency group

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group you want to demote.
3. Select **More** then **Demote to single consistency group**.
4. A warning will advise you that all associated child consistency groups will be deleted and their volumes will be moved under the new single consistency group. Select **Demote** to confirm you understand the impact.

CLI

Beginning with ONTAP 9.14.1, you can demote a consistency group using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Demote a consistency group

1. Demote the consistency group. Use the optional `-new-name` parameter to rename the consistency group.

```
consistency-group demote -vserver SVM_name -consistency-group
parent_consistency_group [-new-name new_consistency_group_name]
```

Modify ONTAP consistency group application and component tags

Beginning with ONTAP 9.12.1, consistency groups support component and application tagging. Application and component tags are a management tool, enabling you to filter and identify different workloads in your consistency groups.

About this task

Consistency groups offer two types of tags:

- **Application tags**: these apply to individual and parent consistency groups. Application tags provide labeling for workloads such as MongoDB, Oracle, or SQL Server. The default application tag for consistency groups is Other.
- **Component tags**: Children in hierarchal consistency groups have component tags instead of application tags. The options for component tags are "data", "logs", or "other". The default value is Other.

You can apply tags when creating consistency groups or after the consistency groups have been created.

> If the consistency group has a SnapMirror active sync relationship, you must use **Other** as the application or component tag.

Steps

Beginning with ONTAP 9.12.1, you can modify application and component tags using System Manager. Beginning with ONTAP 9.14.1, you can modify the application and component tags using the ONTAP CLI.

System Manager

1. Select **Storage > Consistency groups**.
2. Select the consistency group whose tag you want to modify. Select the ⋮ next to the consistency group's name then **Edit**.
3. In the dropdown menu, choose the appropriate application or component tag.
4. Select **Save**.

CLI

Beginning with ONTAP 9.14.1, you can modify the application or component tag of an existing consistency group using the ONTAP CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Modify the application tag

1. Application tags accept a limited number of preset strings. To see the accepted list of strings, run the following command:
   `consistency-group modify -vserver svm_name -consistency-group consistency_group -application-type ?`
2. Choose the appropriate string from the output, the modify the consistency group:
   `consistency-group modify -vserver svm_name -consistency-group consistency_group -application-type application_type`

Modify the component tag

1. Modify the component type. The component type can be data, logs, or other. If you are using SnapMirror active sync, it must be "other."
   `consistency-group modify -vserver svm -consistency-group child_consistency_group -parent-consistency-group parent_consistency_group -application-component-type [data|logs|other]`

Clone an ONTAP consistency group

Beginning with ONTAP 9.12.1, you can clone a consistency group to create a copy of a consistency group and its contents. Cloning a consistency group creates a copy of the consistency group configuration, its metadata such as application type, and all the volumes and its contents such as files, directories, LUNs or NVMe namespaces.

About this task

When cloning a consistency group, you can clone it with its current configuration, but with volume contents as they are or based on an existing consistency group snapshot.

Cloning a consistency group is supported only for the entire consistency group. You cannot clone an individual child consistency group in a hierarchical relationship: only the complete consistency group configuration can be cloned.

When you clone a consistency group, the following components are not cloned:

- iGroups
- LUN maps
- NVMe subsystems
- NVMe namespace subsystem maps

Before you begin

- When you clone a consistency group, ONTAP will not create SMB shares for the cloned volumes if a share name is not specified. * Cloned consistency groups are not mounted if a junction path is not specified.
- If you attempt to clone a consistency group based on a snapshot that does not reflect the consistency group's current constituent volumes, the operation will fail.
- After you clone a consistency group, you need to perform the appropriate mapping operation.

  Refer to Map igroups to multiple LUNs or Map an NVMe namespace to a subsystem for more information.
- Cloning a consistency group is not supported for a consistency group in a SnapMirror active sync relationship or with any associated DP volumes.

System Manager

Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group you want to clone from the **Consistency Group** menu.
3. At the top right of the overview page for the consistency group, select **Clone**.
4. Enter a name for the new, cloned consistency group or accept the default name.
   a. Choose if you want to enable **Thin Provisioning**.
   b. Choose **Split Clone** if you want to dissociate the consistency group from its source and allocate additional disk space for the cloned consistency group.
5. To clone the consistency group in its current state, choose **Add a new Snapshot copy**.

   To clone the consistency group based on a snapshot, choose **Use an existing snapshot**. Selecting this option will open a new sub-menu. Choose the snapshot that you want to use as the basis for the clone operation.
6. Select **Clone**.
7. Return to the **Consistency Group** menu to confirm your consistency group has been cloned.

CLI

Beginning with ONTAP 9.14.1, you can clone a consistency group using the CLI with cluster admin credentials.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Clone a consistency group

1. The `consistency-group clone create` command clones the consistency group at its current point-in-time status. To base the clone operation on a snapshot, include the `-source-snapshot` parameter.

   ```
   consistency-group clone create -vserver svm_name -consistency-group clone_name -source-consistency-group consistency_group_name [-source-snapshot snapshot_name]
   ```

   Learn more about `consistency-group clone create` in the ONTAP command reference.

Next steps

- Map igroups to multiple LUNs
- Map an NVMe namespace to a subsystem

Delete an ONTAP consistency group

If you decide that you no longer need a consistency group, you can delete it.

About this task

- Deleting a consistency group deletes the instance of the consistency group and does *not* impact the constituent volumes or LUNs. Deleting a consistency group does not result in deletion of the snapshots present on each volume, but they will no longer be accessible as consistency group snapshots. The snapshots can, however, continue to be managed as ordinary volume granular snapshots.
- ONTAP automatically deletes a consistency group if all of the volumes in the consistency group are deleted.
- Deleting a parent consistency group results in the deletion of all associated child consistency groups.
- If you are using a version of ONTAP between 9.10.1 to 9.12.0, volumes can only be removed from a consistency group if the volume itself is deleted, in which case the volume is automatically removed from the consistency group. Beginning with ONTAP 9.12.1, you can remove volumes from a consistency group without deleting the consistency group. For more information on this process, refer to Modify a consistency group.

Example 36. Steps

System Manager

1. Select **Storage > Consistency groups**.
2. Select the consistency group you would like to delete.
3. Next to the name of the consistency group, select ⋮ then **Delete**.

CLI

Beginning with ONTAP 9.14.1, you can delete a consistency group using the CLI.

Before you begin

- You must be at the admin privilege level to perform this task.
- Beginning with ONTAP 9.15.1, any user at the admin privilege level can perform this task. In ONTAP 9.14.1, you must be a cluster or SVM administrator to perform this task.

Delete a consistency group

1. Delete the consistency group:

```
consistency-group delete -vserver svm_name -consistency-group
consistency_group_name
```

SnapMirror active sync

Introduction

Learn about ONTAP SnapMirror active sync

SnapMirror active sync (also referred to as SnapMirror Business Continuity *[SM-BC]*), enables business services to continue operating even through a complete site failure, supporting applications to fail over transparently using a secondary copy. There is no manual intervention or custom scripting required to trigger a failover with SnapMirror active sync.

Support for SnapMirror active sync varies depending on your version of ONTAP:

ONTAP version	Supported clusters	Supported protocols	Supported configurations
9.17.1 and later	• AFF • ASA • C-Series • ASA r2	• iSCSI • FC • NVMe	• Asymmetric active/active Asymmetric active/active does not support ASA r2 and NVMe For more information about NVMe support, see NVMe configuration, support, and limitations. • Symmetric active/active
9.15.1 and later	• AFF • ASA • C-Series	• iSCSI • FC	• Asymmetric active/active • Symmetric active/active Symmetric active/active configurations support 2-node clusters in ONTAP 9.15.1. 4-node clusters are supported in ONTAP 9.16.1 and later.
9.9.1 and later	• AFF • ASA • C-Series *	• iSCSI • FC	Asymmetric active/active

Primary and secondary clusters must be of the same type: either ASA, ASA r2, or AFF.

Beginning July 2024, content from technical reports previously published as PDFs has been integrated with ONTAP product documentation. The ONTAP SnapMirror active sync documentation now includes content from *TR-4878: SnapMirror active sync*.

Benefits

SnapMirror active sync provides the following benefits:

- Continuous availability for business-critical applications.
- Ability to host critical applications alternately from primary and secondary sites.
- Simplified application management using consistency groups for dependent write-order consistency.
- The ability to test failover for each application.
- Instantaneous creation of mirror clones without impacting application availability.
- The ability to deploy protected and non-protected workloads in the same ONTAP cluster.
- LUN, NVMe namespace, NVMe subsystem, or storage unit identity remains the same, so the application sees them as a shared virtual device.
- The ability to reuse secondary clusters with flexibility to create instantaneous clones for application usage for dev-test, UAT or reporting purposes without impacting application performance or availability.

SnapMirror active sync allows you to protect your data LUNs or NVMe namespaces, which enables applications to fail over transparently for the purpose of business continuity in the event of a disaster. For more information, see Use cases.

Key concepts

SnapMirror active sync uses consistency groups and either the ONTAP Mediator or, beginning with ONTAP 9.17.1, the ONTAP Cloud Mediator to ensure your data is replicated and served even in the event of a disaster scenario. When planning your SnapMirror active sync deployment, it is important to understand the essential concepts in SnapMirror active sync and its architecture.

Asymmetry and symmetry

In symmetric active/active configurations, both sites can access local storage for active I/O. Symmetric active/active is optimized for clustered applications including VMware vMSC, Windows Failover Cluster with SQL, and Oracle RAC.

In asymmetric active/active configurations data on the secondary site is proxied to a LUN, namespace or storage unit.

For more information, see SnapMirror active sync architecture.

Consistency group

For AFF and ASA systems a consistency group is a collection of FlexVol volumes that provide a consistency guarantee for the application workload that must be protected for business continuity. In ASA r2 systems, a consistency group is a collection of storage units.

The purpose of a consistency group is to take simultaneous snapshot images of a collection of volumes or storage units, thus ensuring crash-consistent copies of the collection at a point in time. A consistency group ensures all volumes of a dataset are quiesced and then snapped at precisely the same point in time. This provides a data-consistent restore point across volumes or storage units supporting the dataset. A consistency group thereby maintains dependent write-order consistency. If you decide to protect applications for business continuity, the group of volumes or storage units corresponding to this application must be added to a consistency group so a data protection relationship is established between a source and a destination consistency group. The source and destination consistency must contain the same number and type of volumes.

Constituent

An individual volume, LUN, or NVMe namespace (beginning with ONTAP 9.17.1) that is part of the consistency group protected in the SnapMirror active sync relationship.

ONTAP Mediator

The ONTAP Mediator receives health information about peered ONTAP clusters and nodes, orchestrating between the two and determining if each node/cluster is healthy and running. ONTAP Mediator provides health information about:

- Peer ONTAP clusters
- Peer ONTAP cluster nodes
- Consistency groups (which define the failover units in a SnapMirror active sync relationship); for each consistency group, the following information is provided:
  - Replication state: Uninitialized, In Sync, or Out of Sync
  - Which cluster hosts the primary copy
  - Operation context (used for planned failover)

With this ONTAP Mediator health information, clusters can differentiate between distinct types of failures and determine whether to perform an automated failover. ONTAP Mediator is one of the three parties in the SnapMirror active sync quorum along with both ONTAP clusters (primary and secondary). To reach consensus, at least two parties in the quorum must agree to a certain operation.

> Beginning with ONTAP 9.15.1, System Manager displays the status of your SnapMirror active sync relationship from either cluster. You can also monitor the ONTAP Mediator's status from either cluster in System Manager. In earlier releases of ONTAP, System Manager displays the status of SnapMirror active sync relationships from the source cluster.

ONTAP Cloud Mediator

ONTAP Cloud Mediator is available beginning with ONTAP 9.17.1. ONTAP Cloud Mediator provides the same services as ONTAP Mediator, except that it is hosted in the cloud using BlueXP.

Planned failover

A manual operation to change the roles of copies in a SnapMirror active sync relationship. The primary sites becomes the secondary, and the secondary becomes the primary.

Primary-first and primary bias

SnapMirror active sync uses a primary-first principle that gives preference to the primary copy to serve I/O in case of a network partition.

Primary-bias is a special quorum implementation that improves availability of a SnapMirror active sync protected dataset. If the primary copy is available, primary-bias comes into effect when the ONTAP Mediator is not reachable from both clusters.

Primary-first and primary bias are supported in SnapMirror active sync beginning with ONTAP 9.15.1. Primary copies are designated in System Manager and output with the REST API and CLI.

Automatic unplanned failover (AUFO)

An automatic operation to perform a failover to the mirror copy. The operation requires assistance from the ONTAP Mediator to detect that the primary copy is unavailable.

Out of Sync (OOS)

When the application I/O is not replicating to the secondary storage system, it will be reported as **out of sync**. An out of sync status means the secondary volumes are not synchronized with the primary (source) and that SnapMirror replication is not occurring.

If the mirror state is `Snapmirrored`, this indicates a transfer failure or failure due to an unsupported operation.

SnapMirror active sync supports automatic resync, enabling copies to return to an InSync state.

Beginning with ONTAP 9.15.1, SnapMirror active sync supports automatic reconfiguration in fan-out configurations.

Uniform and non-uniform configuration

- **Uniform host access** means that hosts from both sites are connected to all paths to storage clusters on both sites. Cross-site paths are stretched across distances.
- **Non-uniform host access** means hosts in each site are connected only to the cluster in the same site. Cross-site paths and stretched paths aren't connected.

> Uniform host access is supported for any SnapMirror active sync deployment; non-uniform host access is only supported for symmetric active/active deployments.

Zero RPO

RPO stands for recovery point objective, which is the amount of data loss deemed acceptable during a given time period. Zero RPO signifies that no data loss is acceptable.

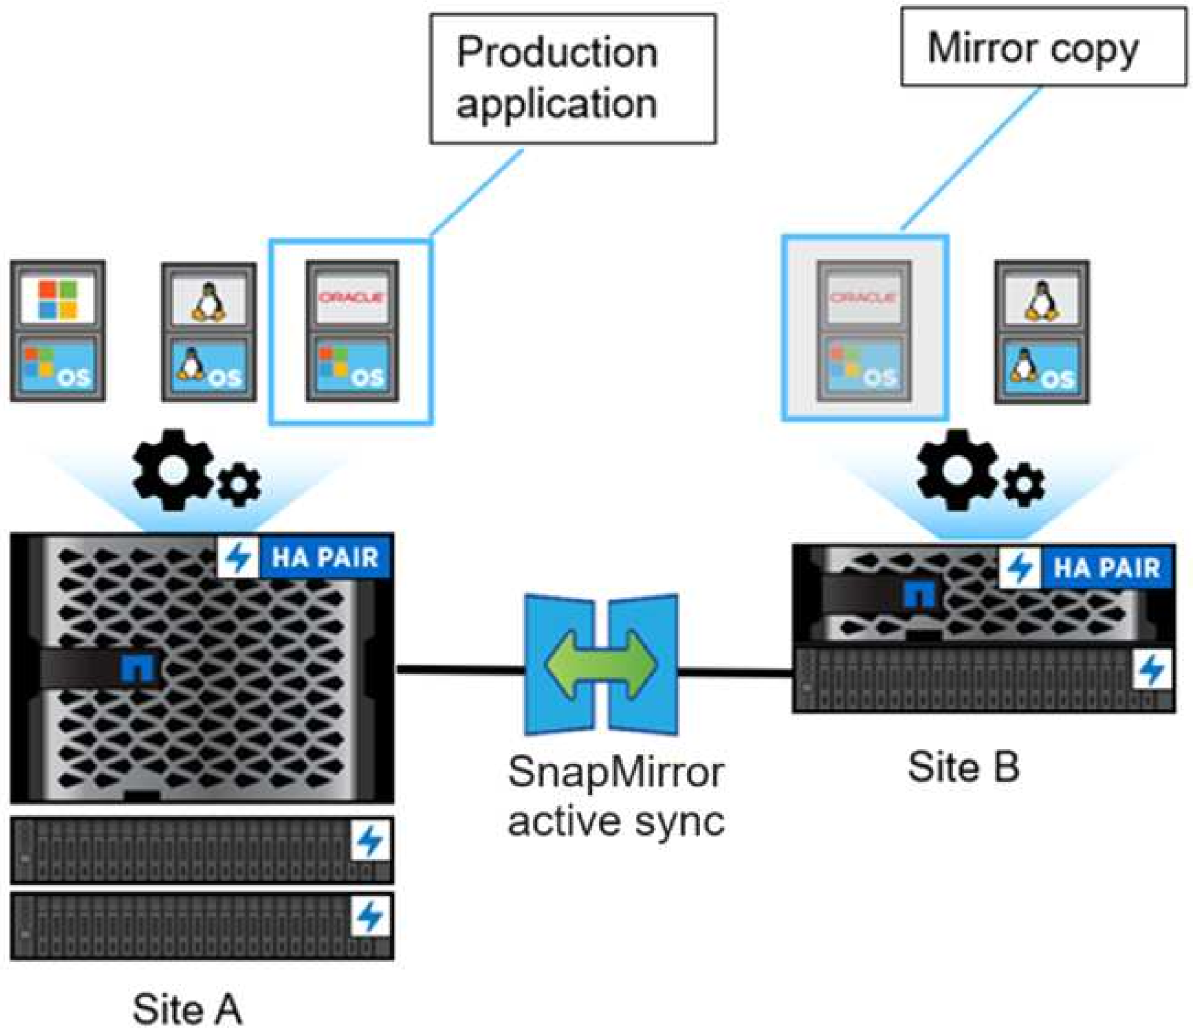
Zero RTO

RTO stands for recovery time objective, which is the amount of time that is deemed acceptable for an application to return to normal operations non-disruptively following an outage, failure, or other data loss event. Zero RTO signifies that no amount of downtime is acceptable.

ONTAP SnapMirror active sync architecture

The SnapMirror active sync architecture enables active workloads on both clusters, where primary workloads can be served simultaneously from both clusters. Regulations for financial institutions in some countries require businesses to be periodically serviceable from their secondary data centers as well, called "Tick-Tock" deployments, which SnapMirror active sync enables.

The data protection relationship to protect for business continuity is created between the source storage system and destination storage system, by adding the application specific LUNs or NVMe namespaces from different volumes within a storage virtual machine (SVM) to the consistency group. Under normal operations, the enterprise application writes to the primary consistency group, which synchronously replicates this I/O to the mirror consistency group.



Even though two separate copies of the data exist in the data protection relationship, because SnapMirror active sync maintains the same LUN or NVMe namespace identity, the application host sees this as a shared virtual device with multiple paths while only one LUN or NVMe namespace copy is being written to at a time. When a failure renders the primary storage system offline, ONTAP detects this failure and uses the Mediator for re-confirmation; if neither ONTAP nor the Mediator are able to ping the primary site, ONTAP performs the automatic failover operation. This process results in failing over only a specific application without the need for the manual intervention or scripting which was previously required for the purpose of failover.

Other points to consider:

- Unmirrored volumes which exist outside of protection for business continuity are supported.
- Only one other SnapMirror asynchronous relationship is supported for volumes being protected for business continuity.
- Cascade topologies are not supported with protection for business continuity.

The role of mediators

SnapMirror active sync uses a mediator to act as a passive witness to SnapMirror active sync copies. In the event of a network partition or unavailability of one copy, SnapMirror active sync uses the mediator to determine which copy continues to serve I/O, while discontinuing I/O on the other copy. In addition to the on-premises ONTAP Mediator, beginning with ONTAP 9.17.1, you can install ONTAP Cloud Mediator to provide the same functionality in a cloud deployment. You can use ONTAP Mediator or ONTAP Cloud Mediator, but you cannot use both at the same time.

The Mediator plays a crucial role in SnapMirror active sync configurations as a passive quorum witness, ensuring quorum maintenance and facilitating data access during failures. It acts as a ping proxy for controllers to determine liveliness of peer controllers. Although the Mediator does not actively trigger switchover operations, it provides a vital function by allowing the surviving node to check its partner’s status during network communication issues. In its role as a quorum witness, the ONTAP Mediator provides an alternate path (effectively serving as a proxy) to the peer cluster.

Furthermore, it allows clusters to get this information as part of the quorum process. It uses the node management LIF and cluster management LIF for communication purposes. It establishes redundant connections through multiple paths to differentiate between site failure and InterSwitch Link (ISL) failure. When a cluster loses connection with the Mediator software and all its nodes due to an event, it is considered not reachable. This triggers an alert and enables automated failover to the mirror consistency group in the secondary site, ensuring uninterrupted I/O for the client. The replication data path relies on a heartbeat mechanism, and if a network glitch or event persists beyond a certain period, it can result in heartbeat failures, causing the relationship to go out-of-sync. However, the presence of redundant paths, such as LIF failover to another port, can sustain the heartbeat and prevent such disruptions.

ONTAP Mediator

ONTAP Mediator is installed in a third failure domain, distinct from the two ONTAP clusters it monitors. There are three key components in this setup:

- Primary ONTAP cluster hosting the SnapMirror active sync primary consistency group
- Secondary ONTAP cluster hosting the mirror consistency group
- ONTAP Mediator

ONTAP Mediator is used for the following purposes:

- Establish a quorum
- Continuous availability via automatic failover (AUFO)
- Planned failovers (PFO)

ⓘ ONTAP Mediator 1.7 can manage ten cluster pairs for the purpose of business continuity.

ⓘ When the ONTAP Mediator is not available, you cannot perform planned or automated failovers. The application data continues to synchronously replicate without any interruption to for zero data loss.

ONTAP Cloud Mediator

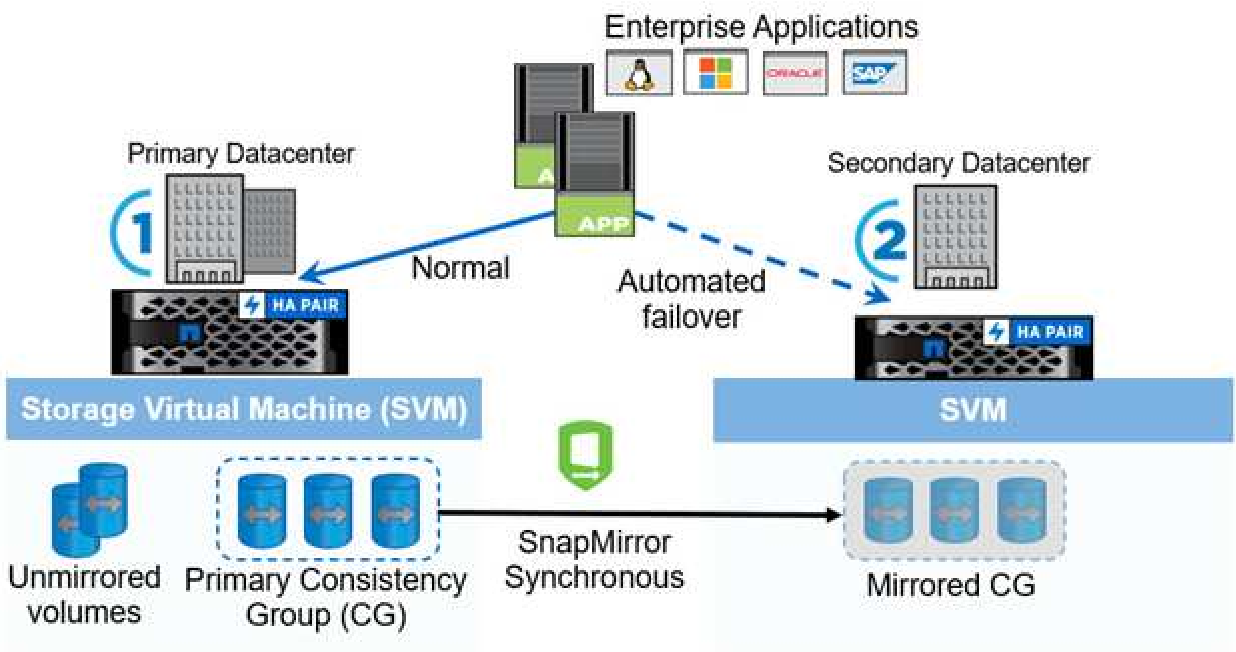
Beginning with ONTAP 9.17.1, ONTAP Cloud Mediator is available as a cloud-based service in BlueXP for use with SnapMirror active sync. Similar to ONTAP Mediator, ONTAP Cloud Mediator provides the following functionality in a SnapMirror active sync relationship:

- Provides a persistent and fenced store for HA or SnapMirror active sync metadata.
- Serves as ping proxy for controller liveliness.
- Provides synchronous node health query functionality to aid in quorum determination.

The ONTAP Cloud Mediator helps simplify SnapMirror active sync deployment by using the BlueXP cloud service as a third site that you do not need to manage. The ONTAP Cloud Mediator service provides the same functionality as the on-premises ONTAP Mediator; however, ONTAP Cloud Mediator reduces the operational complexity of maintaining a third site. In contrast, ONTAP Mediator is available as a package and must be installed on a Linux host running at a third site with independent power and network infrastructure for its operations.

SnapMirror active sync operation workflow

The following figure illustrates the design of SnapMirror active sync at a high level.



The diagram shows an enterprise application that is hosted on an storage VM (SVM) at the primary data center. The SVM contains five volumes, three of which are part of a consistency group. The three volumes in the consistency group are mirrored to a secondary data center. In normal circumstances, all write operations are performed to the primary data center; in effect, this data center serves as the source for I/O operations, while the secondary data center serves as a destination.

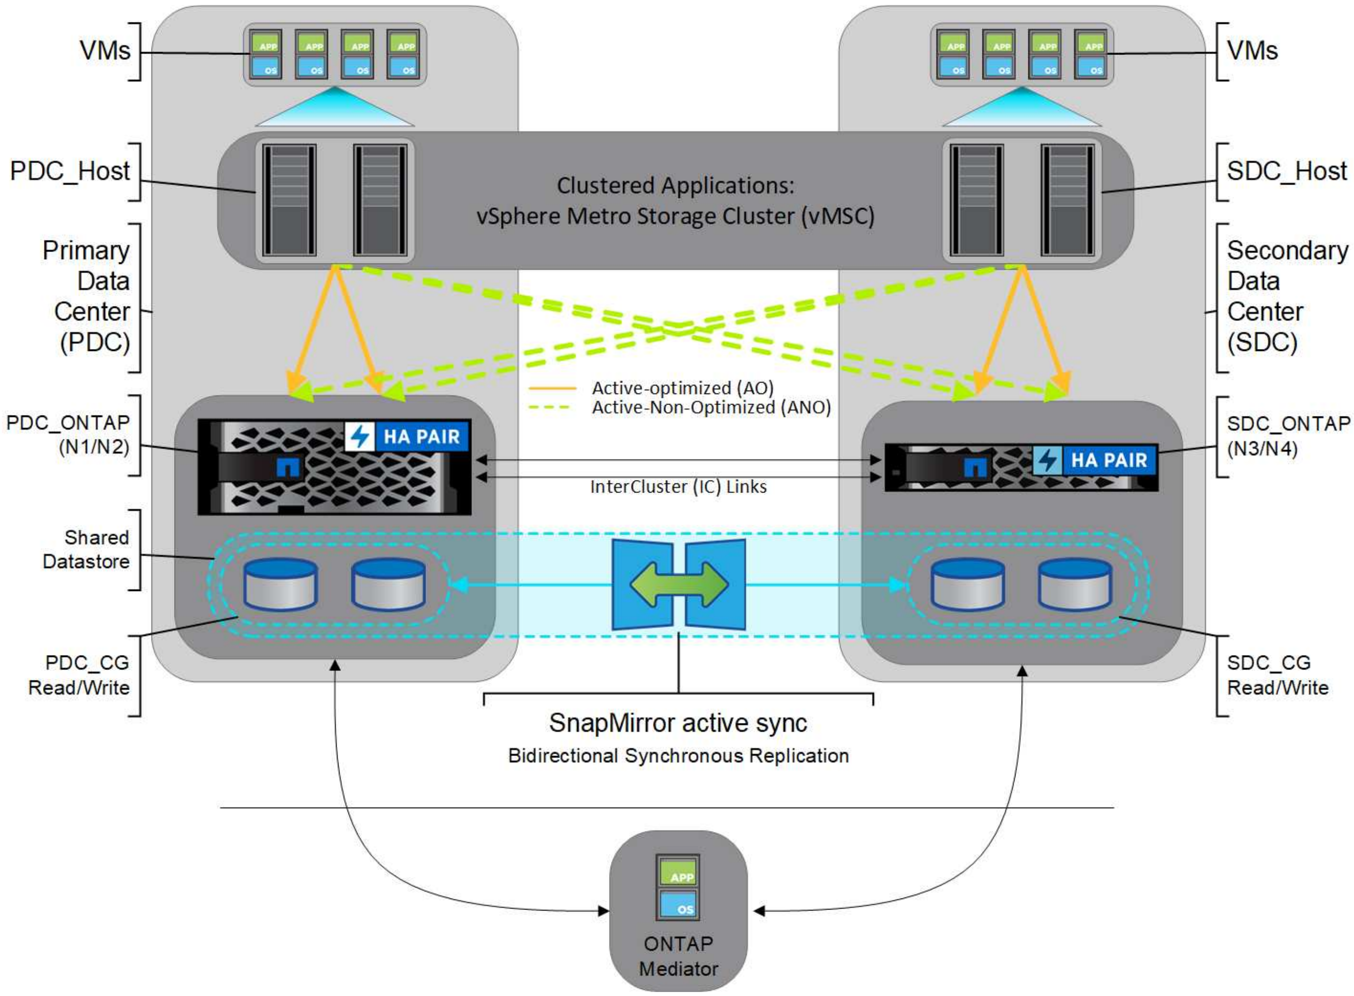
In the event of a disaster scenario at the primary data center, ONTAP directs the secondary data center to act as the primary, serving all I/O operations. Only the volumes that are mirrored in the consistency group are served. Any operations pertaining to the other two volumes on the SVM is be affected by the disaster event.

Symmetric active/active

SnapMirror active sync offers asymmetric and symmetric solutions.

In *asymmetric configurations*, the primary storage copy exposes an active-optimized path and actively serves client I/O. The secondary site uses a remote path for I/O. The storage paths for the secondary site are considered active-non-optimized. Access to the write LUN is proxied from the secondary site. NVMe protocol is not supported in asymmetric configurations.

In *symmetric active/active configurations*, active-optimized paths are exposed on both sites, are host specific, and are configurable, meaning hosts on either side are able to access local storage for active I/O. Beginning with ONTAP 9.16.1, symmetric active/active is supported on clusters with up to four nodes. Beginning with ONTAP 9.17.1, symmetric active/active configurations support NVMe protocol on two node clusters.



Symmetric active/active is targeted for clustered applications including VMware Metro Storage Cluster, Oracle RAC, and Windows Failover Clustering with SQL.

Use cases for ONTAP SnapMirror active sync

The demands of a globally connected business environment demand rapid recovery of business-critical application data with zero data loss in the event of a disruption such as a cyber attack, power outage, or natural disaster. These demands are heightened in arenas such as finance and those adhering to regulatory mandates such as the General Data Protection Regulation (GDPR).

SnapMirror active sync provides the following use cases:

Application deployment for zero recovery time objective (RTO)

In a SnapMirror active sync deployment, you have a primary and secondary cluster. A LUN in the primary cluster (`1LP`) has a mirror (`L1s`) on the secondary; both LUNs share the same serial ID and are reported as read-write LUNs to the host. In asymmetric configurations read and write operations, however, are only serviced to the primary LUN, `1LP`. Any writes to the mirror `L1S` are served by proxy.

Application deployment for zero RTO or transparent application failover (TAF)

TAF is based on host MPIO software-based path failover to achieve non-disruptive access to the storage. Both LUN copies—for example, primary (L1P) and mirror copy (L1S)--have the same identity (serial number) and are reported as read-writable to the host. In asymmetric configurations however, reads and writes are serviced only by the primary volume. I/Os issued to the mirror copy are proxied to the primary copy. The host's preferred path to L1 is VS1:N1 based on asymmetric logical unit access (ALUA) access state Active Optimized (A/O). ONTAP Mediator is required as part of the deployment, primarily to perform failover (planned or unplanned) in the event of a storage outage on the primary.

TAF operates in two modes: Automated Failover and Automated Failover Duplex. With Automated Failover, reads and writes are serviced only by the primary volume, therefore, IOs issued to the mirror copy (which cannot service writes on its own) are proxied to the primary copy. With Automated Failover Duplex, both the primary and secondary copies can service IOs so no proxy is necessary.

If you are using NVMe for host access with ONTAP 9.17.1, only Automated Failover Duplex is supported.

SnapMirror active sync uses ALUA, a mechanism that allows an application host multipathing software with paths advertised with priorities and access availability for the application host communication with the storage array. ALUA marks active optimized paths to the controllers owning the LUN and others as active non-optimized paths, used only if the primary path fails.

SnapMirror active sync with NVMe protocol uses ANA, which enables application hosts to discover optimized and non-optimized paths to NVMe namespaces that are being protected. The ONTAP NVMe target publishes the appropriate path states to enable application hosts to use the optimal path for a protected NVMe namespace.

Clustered applications

Clustered applications including VMware Metro Storage Cluster, Oracle RAC, and Windows Failover Clustering with SQL require simultaneous access so the VMs can be failed over to other site without any performance overhead. SnapMirror active sync symmetric active/active serves IO locally with bidirectional replication to meet the requirements of clustered applications. Beginning with ONTAP 9.16.1, symmetric active/active is supported in a configuration in four-node clusters, expanding from the two-node cluster limit in ONTAP 9.15.1.

Disaster scenario

Synchronously replicate multiple volumes for an application between sites at geographically dispersed locations. You can automatically failover to the secondary copy in case of disruption of the primary, thus enabling business continuity for tier one applications. When the site hosting the primary cluster experiences a disaster, the host multipathing software marks all paths through the cluster as down and uses paths from the secondary cluster. The result is a non-disruptive failover enabled by ONTAP Mediator to the mirror copy.

Windows failover

SnapMirror active sync provides flexibility with easy-to-use application-level granularity and automatic failover. SnapMirror active sync uses proven SnapMirror synchronous replication over IP network to replicate data at high speeds over LAN or WAN, to achieve high data availability and fast data replication for your business-critical applications such as Oracle, Microsoft SQL Server, and so on, in both virtual and physical environments.

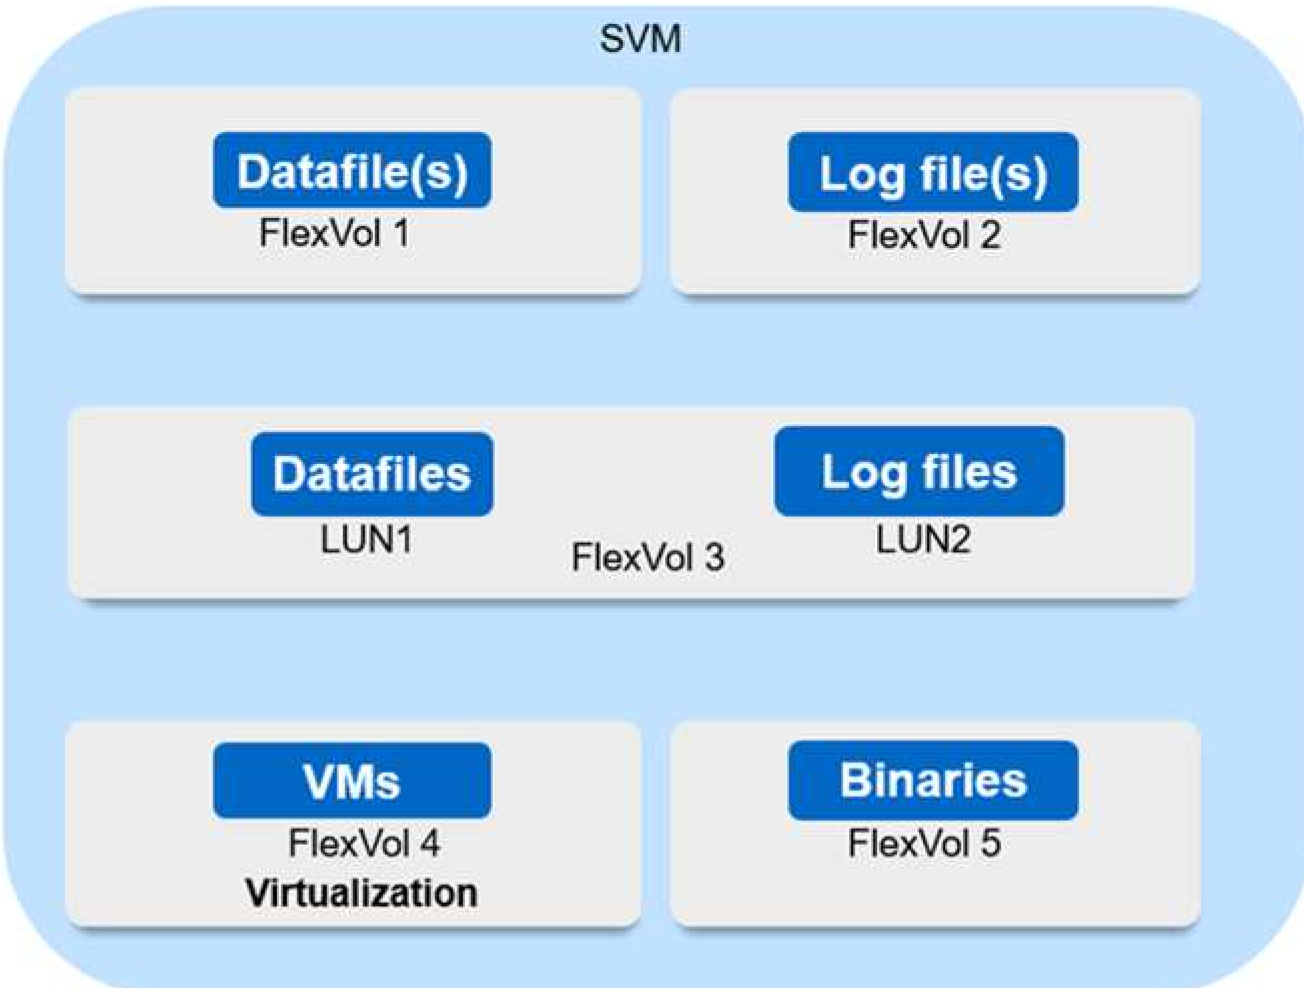
SnapMirror active sync enables mission-critical business services to continue operating even through a complete site failure, with TAF to the secondary copy. No manual intervention or no additional scripting are required to trigger this failover.

Deployment strategy and best practices for ONTAP SnapMirror active sync

It is important that your data protection strategy clearly identifies the workloads threats need to be protected for business continuity. The most critical step in your data protection strategy is to have clarity in your enterprise application data layout so that you can decide how you are distributing the volumes and protecting business continuity. Because failover occurs at the consistency group level on a per-application basis, make sure to add the necessary data volumes to the consistency group.

SVM configuration

The diagram captures a recommended storage VM (SVM) configuration for SnapMirror active sync.



- For data volumes:
  - Random read workloads are isolated from sequential writes; therefore, depending on the database size, the data and log files are typically placed on separate volumes.
    - For large critical databases, the single data file is on FlexVol 1 and its corresponding log file is on FlexVol 2.
    - For better consolidation, small-to-medium-size noncritical databases are grouped such that all the data files are on FlexVol 1 and their corresponding log files are on FlexVol 2. However, you will lose application-level granularity through this grouping.
  - Another variant is to have all the files within the same FlexVol 3, with data files in LUN1 and its log files in LUN 2.
- If your environment is virtualized, you would have all the VMs for various enterprise applications shared in a datastore. Typically, the VMs and application binaries are asynchronously replicated using SnapMirror.

Plan

Prerequisites for ONTAP SnapMirror active sync

When planning your SnapMirror active sync deployment, ensure you have met the various hardware, software, and system configuration requirements.

Hardware

The following table outlines the supported NetApp cluster configurations.

Cluster type	Supported models	Supported features	Maximum supported cluster nodes
AFF	A-Series, C-Series	Automated Failover Duplex (Symmetric Active/Active), Automated Failover (Asymmetric Active/Active)	• 2 (ONTAP 9.9.1 or later) • 4 (ONTAP 9.16.1 with Symmetric Active/Active configurations)
ASA	A-Series, C-Series	Automated Failover Duplex (Symmetric Active/Active), Automated Failover (Asymmetric Active/Active)	• 2 (ONTAP 9.9.1 or later • 4 (ONTAP 9.16.1 with Symmetric Active/Active configurations)
ASA r2	All	Automated Failover Duplex (Symmetric Active/Active)	2

The table below outlines the capability for replication between cluster types.

Cluster type 1	Cluster type 2	Replication supported?
AFF A-Series	AFF C-Series	Yes
ASA r2 A-Series	ASA r2 C-Series	Yes
AFF	ASA	No
ASA	ASA r2	No
ASA r2	ASA r2	Yes

Software

- ONTAP 9.9.1 or later

- ONTAP Mediator 1.2 or later
- A Linux server or virtual machine for ONTAP Mediator running one of the following:

ONTAP Mediator version	Supported Linux versions
1.10	• Red Hat Enterprise Linux ◦ Compatible: 9.5 [1] ◦ Recommended: 10, 9.6, 9.4, and 8.10 • Rocky Linux 10, 9.6, and 8.10
1.9.1	• Red Hat Enterprise Linux ◦ Compatible: 9.3, 9.1, 8.9, 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.5, 9.4, 9.2, 9.0, 8.10, and 8.8 • Rocky Linux 9.5 and 8.10
1.9	• Red Hat Enterprise Linux ◦ Compatible: 9.3, 9.1, 8.9, 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.5, 9.4, 9.2, 9.0, 8.10, and 8.8 • Rocky Linux 9.5 and 8.10
1.8	• Red Hat Enterprise Linux: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.4, 9.3, 9.2, 9.1, 9.0, 8.10, 8.9, and 8.8 • Rocky Linux 9.4 and 8.10
1.7	• Red Hat Enterprise Linux: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.3, 9.2, 9.1, 9.0, 8.9, and 8.8 • Rocky Linux 9.3 and 8.9
1.6	• Red Hat Enterprise Linux: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.2, 9.1, 9.0, and 8.8 • Rocky Linux 9.2 and 8.8
1.5	• Red Hat Enterprise Linux: 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6

1.4	• Red Hat Enterprise Linux: 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6
1.3	• Red Hat Enterprise Linux: 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6
1.2	• Red Hat Enterprise Linux: 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6

1. Compatible means that Red Hat no longer supports these RHEL versions, but ONTAP Mediator can still be installed on them.

Licensing

- SnapMirror synchronous license must be applied on both clusters.
- SnapMirror license must be applied on both clusters.

> ⓘ If your ONTAP storage systems were purchased before June 2019, see NetApp ONTAP Master License Keys to get the required SnapMirror synchronous license.

Networking environment

- Inter-cluster latency round trip time (RTT) must be less than 10 milliseconds.
- Beginning with ONTAP 9.14.1, SCSI-3 persistent reservations are supported with SnapMirror active sync.

Supported protocols

SnapMirror active sync supports SAN protocols.

- The FC and iSCSI protocols are supported beginning with ONTAP 9.9.1.
- The NVMe protocol is supported with VMware workloads beginning with ONTAP 9.17.1.

  > ⓘ NVMe/TCP with VMware depends on the resolution of VMware Bug ID: TR1049746.

  SnapMirror active sync does not support the following with the NVMe protocol:

  - 4-node symmetric active/active configurations
  - Changes in consistency group size

    You cannot expand or shrink a consistency group when using the NVMe protocol with SnapMirror active sync.

  - Coexistence of LUNs and namespaces in the same consistency group is not supported.

IPspace

The default IPspace is required by SnapMirror active sync for cluster peer relationships. Custom IPspace is not supported.

NTFS Security Style

NTFS security style is **not** supported on SnapMirror active sync volumes.

ONTAP Mediator

- ONTAP Mediator must be provisioned externally and attached to ONTAP for transparent application failover.
- To be fully functional and to enable automatic unplanned failover, the external ONTAP Mediator should be provisioned and configured with ONTAP clusters.
- ONTAP Mediator must be installed in a third failure domain, separate from the two ONTAP clusters.
- When installing ONTAP Mediator, you should replace the self-signed certificate with a valid certificate signed by a mainstream reliable CA.
- For more information about ONTAP Mediator, see Prepare to install ONTAP Mediator.

Other prerequisites

- SnapMirror active sync relationships are not supported on read-write destination volumes. Before you can use a read-write volume, you must convert it to a DP volume by creating a volume-level SnapMirror relationship and then deleting the relationship. For details, see Convert an existing SnapMirror relationships to SnapMirror active sync.
- Storage VMs using SnapMirror active sync cannot be joined to Active Directory as a client computed.

Further information

- Hardware Universe
- ONTAP Mediator overview

ONTAP SnapMirror active sync interoperability

SnapMirror active sync is compatible with numerous operating systems, application hosts, and other features in ONTAP.

> For specific supportability and interoperability details not covered here, consult the Interoperability Matrix Tool (IMT).

Application hosts

SnapMirror active sync support applications hosts including Hyper-V, Red Hat Enterprise Linux (RHEL), VMware, VMware vSphere Metro Storage Cluster (vMSC), Windows Server, and, beginning with ONTAP 9.14.1, Windows Server Failover Cluster.

Operating systems

SnapMirror active sync is supported with numerous operating systems, including:

- AIX via PVR (beginning ONTAP 9.11.1)
- HP-UX (beginning ONTAP 9.10.1)

- Solaris 11.4 (beginning ONTAP 9.10.1)
- NVMe support with ESXi (beginning ONTAP 9.17.1)

AIX

Beginning with ONTAP 9.11.1, AIX is supported with SnapMirror active sync via standard engineering Feature Policy Variance Request (FPVR) with the agreement that the following stipulations are understood:

- SnapMirror active sync can provide zero RPO data protection, but the failover process with AIX requires additional steps to recognize the path change. LUNs that are not part of a root volume group will experience an I/O pause until a `cfgmgr` command is run. This can be automated, and most applications will resume operations without further disruption.
- LUNs that are part of a root volume group should generally not be protected with SnapMirror active sync. It's not possible to run the `cfgmgr` command after a failover, meaning that a reboot is required to recognize the changes in SAN paths. You can still achieve zero RPO data protection of the root volume group, but failover will be disruptive.

Consult your NetApp account team for further information about SnapMirror active sync with AIX.

HP-UX

Beginning with ONTAP 9.10.1, SnapMirror active sync for HP-UX is supported.

Automatic unplanned failover with HP-UX

An automatic unplanned failover (AUFO) event on the isolated master cluster may be caused by dual event failure when the connection between the primary and the secondary cluster is lost and the connection between the primary cluster and the mediator is also lost. This is considered a rare event, unlike other AUFO events.

- In this scenario, it might take more than 120 seconds for I/O to resume on the HP-UX host. Depending on the applications that are running, this might not lead to any I/O disruption or error messages.
- To remediate, you must restart applications on the HP-UX host that have a disruption tolerance of less than 120 seconds.

Solaris

Beginning with ONTAP 9.10.1, SnapMirror active sync supports Solaris 11.4.

To ensure the Solaris client applications are non-disruptive when an unplanned site failover switchover occurs in an SnapMirror active sync environment, modify the default Solaris OS settings. To configure Solaris with the recommended settings, see the Knowledge Base article Solaris Host support recommended settings in SnapMirror active sync.

ONTAP interoperability

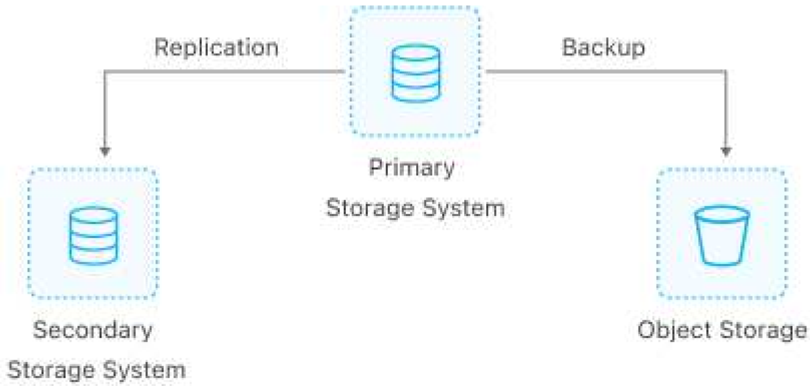
SnapMirror active sync integrates with components of ONTAP to extends its data protection capabilities.

FabricPool

SnapMirror active sync supports source and destination volumes on FabricPool aggregates with tiering policies of None, Snapshot or Auto. SnapMirror active sync does not support FabricPool aggregates using a tiering policy of All.

Fan-out configurations

In fan-out configurations, your source volume can be mirrored to a SnapMirror active sync destination endpoint and to one or more SnapMirror asynchronous relationships.



SnapMirror active sync supports fan-out configurations with the `MirrorAllSnapshots` policy and, beginning with ONTAP 9.11.1, the `MirrorAndVault` policy. Fan-out configurations are not supported in SnapMirror active sync with the `XDPDefault` policy.

Beginning with ONTAP 9.15.1, SnapMirror active sync supports automatic reconfiguration in the fan-out leg after a failover event. If the failover from the primary to the secondary site has succeeded, the tertiary site is automatically reconfigured to treat the secondary site as the source. The async fan-out leg can be a consistency group relationship or an independent volume relationship. The reconfiguration will work for either of the cases. Reconfiguration is triggered by either a planned or unplanned failover. Reconfiguration also occurs upon failback to the primary site.

For information about managing your fan-out configuration in earlier releases of ONTAP, see resume protection in the fan-out configuration.

NDMP restore

Beginning with ONTAP 9.13.1, you can use NDMP to copy and restore data with SnapMirror active sync. Using NDMP allows you to move data onto the SnapMirror active sync source to complete a restore without pausing protection. This is particularly useful in fan-out configurations.

SnapCenter

SnapMirror active sync is supported with SnapCenter beginning with SnapCenter 5.0. SnapCenter enables the creation of snapshots that can be used to protect and recover applications and virtual machines, enabling always available storage solutions with application-level granularity.

SnapRestore

SnapMirror active sync supports partial and single file SnapRestore.

Single file SnapRestore

Beginning with ONTAP 9.11.1, single-file SnapRestore is supported for SnapMirror active sync volumes. You can restore a single file from a snapshot replicated from the SnapMirror active sync source to the destination. Because volumes can contain one or more LUNs, this feature helps you implement a less disruptive restore operation, granularly restoring a single LUN without disrupting the other LUNs. Single File SnapRestore has two options: in-place and out-of-place.

Partial file SnapRestore

Beginning in ONTAP 9.12.1, partial LUN restore is supported for SnapMirror active sync volumes. You can restore a data from application-created snapshots that have been replicated between the SnapMirror active sync source (volume) and the destination (snapshot) volumes. Partial LUN or file restore may be necessary if you need to restore a database on a host that stores multiple databases on the same LUN. Using this functionality requires you to know the starting byte offset of the data and byte count.

Large LUNs and large volumes

Support for large LUNs and large volumes (greater than 100 TB) depends on the version of ONTAP you are using and your platform.

ONTAP 9.12.1P2 and later

- For ONTAP 9.12.1 P2 and later, SnapMirror active sync supports Large LUNs and large volumes greater than 100 TB on ASA and AFF (A-Series and C-Series). Primary and secondary clusters must be of the same type: either ASA or AFF. Replication from AFF A-Series to AFF C-Series and vice versa is supported.

> For ONTAP Releases 9.12.1P2 and later, you must ensure that both the primary and secondary clusters are either All-Flash SAN Arrays (ASA) or All Flash Array (AFF), and that they both have ONTAP 9.12.1 P2 or later installed. If the secondary cluster is running a version earlier than ONTAP 9.12.1P2 or if the array type is not the same as primary cluster, the synchronous relationship can go out of sync if the primary volume grows larger than 100 TB.

ONTAP 9.9.1 - 9.12.1P1

- For ONTAP releases between ONTAP 9.9.1 and 9.12.1 P1 (inclusive), Large LUNs and large volumes greater than 100TB are supported only on All-Flash SAN Arrays. Replication from AFF A-Series to AFF C-Series and vice versa is supported.

> For ONTAP releases between ONTAP 9.9.1 and 9.12.1 P2, you must ensure that both the primary and secondary clusters are All-Flash SAN Arrays, and that they both have ONTAP 9.9.1 or later installed. If the secondary cluster is running a version earlier than ONTAP 9.9.1 or if it is not an All-Flash SAN Array, the synchronous relationship can go out of sync if the primary volume grows larger than 100 TB.

Object limits for ONTAP SnapMirror active sync

When preparing to use SnapMirror active sync, be aware of the following object limits.

Consistency groups in a cluster

Consistency group limits for a cluster with SnapMirror active sync are calculated based on relationships and depend on the version of ONTAP used. Limits are platform-independent.

ONTAP version	Maximum number of relationships
ONTAP 9.11.1 and later	50*
ONTAP 9.10.1	20
ONTAP 9.9.1	5

* Beginning with ONTAP 9.16.1, SnapMirror active sync supports four-node clusters in symmetric active/active configurations. In a four-node cluster, 100 consistency groups are supported.

Volumes per consistency group

The maximum number of volumes per consistency group with SnapMirror active sync is platform independent.

ONTAP version	Maximum number of volumes supported in a consistency group relationship
ONTAP 9.15.1 and later	80
ONTAP 9.10.1-9.14.1	16
ONTAP 9.9.1	12

Volumes

Volume limits in SnapMirror active sync are calculated based on the number of endpoints, not the number of relationships. A consistency group with 12 volumes contributes 12 endpoints on both the primary and secondary cluster. Both SnapMirror active sync and SnapMirror synchronous relationships contribute to the total number of endpoints.

> These limits apply to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, or ASA A20), see ASA r2 documentation.

The maximum endpoints per platform are included in the following table.

Platform	Endpoints per HA for SnapMirror active sync			Overall sync and SnapMirror active sync endpoints per HA		
	ONTAP 9.11.1 and later	ONTAP 9.10.1	ONTAP 9.9.1	ONTAP 9.11.1 and later	ONTAP 9.10.1	ONTAP 9.9.1
AFF	400*	200	60	400	200	80
ASA	400*	200	60	400	200	80

* Beginning with ONTAP 9.16.1, SnapMirror active sync supports four-node clusters in symmetric active/active configurations. The total limit for a four-node cluster is 800 endpoints.

SAN object limits

SAN object limits are included in the following table. The limits apply regardless of the platform.

Object in a SnapMirror active sync relationship	Count
LUNs per volume	• 256 (ONTAP 9.9.1 - ONTAP 9.15.0) • 512 (ONTAP 9.15.1 and later)
Number of unique LUNs, namespaces, or storage units per 2 x 2 SnapMirror active sync solution	4,096
Number of unique LUNs, namespaces, or storage units per 4 x 4 SnapMirror active-sync solution (available beginning with ONTAP 9.16.1)	6,144
LIFs per SVM (with at least one volume in a SnapMirror active sync relationship)	256
Inter-cluster LIFs per node	4
Inter-cluster LIFs per cluster	8

NVMe object limits

Beginning with ONTAP 9.17.1, SnapMirror active sync supports the NVMe protocol. NVMe object limits are included in the following table.

Maximum objects in a SnapMirror active sync relationship	Count
Number of namespace maps per node	4K
Cluster size	2 nodes
Number of consistency groups per HA pair	50
Number of volumes in a single NVMe SnapMirror active sync consistency group	80
Number of volumes in an HA pair	400
NVMe subsystems per consistency group	16
Namespace maps per consistency group	256

Configure

Configure ONTAP clusters for SnapMirror active sync

SnapMirror active sync uses peered clusters to protect your data in the event of a failover scenario. Before you configure ONTAP Mediator or ONTAP Cloud Mediator for SnapMirror active sync, you must first ensure the cluster is configured correctly.

Before you begin

Before you configure ONTAP Mediator or ONTAP Cloud Mediator, you should confirm the following:

1. A cluster peering relationship exists between the clusters.

   > The default IPspace is required by SnapMirror active sync for cluster peer relationships. A custom IPspace isn't supported.

   Creating a cluster peer relationship

2. The SVMs are created on each cluster.

   Creating an SVM

3. A peer relationship exists between the SVMs on each cluster.

   Creating an SVM peering relationship

4. The volumes exist for your LUNs.

   Creating a volume

5. At least one SAN LIF is created on each node in the cluster.

   Considerations for LIFs in a cluster SAN environment

   Creating a LIF

6. The necessary LUNs are created and mapped to an igroup, which is used to map LUNs to the initiator on the application host.

   Create LUNs and map igroups

7. The application host is re-scanned to discover any new LUNs.

Configure the ONTAP Mediator for SnapMirror active sync

SnapMirror active sync uses peered clusters to protect your data in the event of a failover scenario. ONTAP Mediator is a key resource that enables business continuity by monitoring the health of each cluster. To configure SnapMirror active sync, you must first install ONTAP Mediator and verify that your primary and secondary clusters are configured properly.

Once you have installed ONTAP Mediator and configured your clusters, initialize ONTAP Mediator for SnapMirror active sync using self-signed certificates. You must then create, initialize, and map the consistency group for SnapMirror active sync.

ONTAP Mediator

ONTAP Mediator provides a persistent and fenced store for high availability (HA) metadata used by the ONTAP clusters in a SnapMirror active sync relationship. Additionally, ONTAP Mediator provides a synchronous node health query functionality to aid in quorum determination and serves as a ping proxy for controller liveliness detection.

Each cluster peer relationship can only be associated with a single ONTAP Mediator instance. HA Mediator instances aren't supported. When a cluster is in several peer relationships with other clusters, the following ONTAP Mediator options are available:

- If SnapMirror active sync is configured on each relationship, each cluster peer relationship can have its own unique ONTAP Mediator instance.
- The cluster can use the same ONTAP Mediator instance for all peer relationships.

For example, if cluster B has a peer relationship with cluster A, cluster C, and cluster D, all three cluster peer relationships can have a unique associated ONTAP Mediator instance when SnapMirror active sync is configured on each relationship. Alternatively, cluster B can use the same ONTAP Mediator instance for all three peer relationships. In this scenario, the same instance of ONTAP Mediator is listed three times for the cluster.

Beginning with ONTAP 9.17.1, you can configure ONTAP Cloud Mediator to monitor the health of your cluster in a SnapMirror active sync configuration, however, you cannot use both Mediators at the same time.

Prerequisites for ONTAP Mediator

- ONTAP Mediator includes its own set of prerequisites. You must meet these prerequisites before installing ONTAP Mediator.

  For more information, see Prepare to install the ONTAP Mediator service.

- By default, the ONTAP Mediator provides service through TCP port 31784. You should make sure that port 31784 is open and available between the ONTAP clusters and the ONTAP Mediator.

Install ONTAP Mediator and confirm cluster configuration

Perform each of the following steps to install ONTAP Mediator and verify the cluster configuration. For each step, you should confirm that the specific configuration has been performed. Each step includes a link to the specific procedure that you need to follow.

Steps

1. Install ONTAP Mediator before verifying that your source and destination clusters are configured correctly.

   Prepare to install or upgrade ONTAP Mediator

2. Confirm that a cluster peering relationship exists between the clusters.

   > ⓘ The default IPspace is required by SnapMirror active sync for cluster peer relationships. A custom IPspace isn't supported.

   Configure ONTAP clusters for SnapMirror active sync

Initialize ONTAP Mediator for SnapMirror active sync using self-signed certificates

Once you have installed ONTAP Mediator and confirmed you cluster configuration, you must initialize ONTAP Mediator for cluster monitoring. You can initialize ONTAP Mediator using System Manager or the ONTAP CLI.

System Manager

With System Manager, you can configure ONTAP Mediator for automated failover. You can also replace the self-signed SSL and CA with the third party validated SSL Certificate and CA if you have not already done so.

> ⓘ From ONTAP 9.14.1 through 9.8, SnapMirror active sync is referred to as SnapMirror Business Continuity (SM-BC).

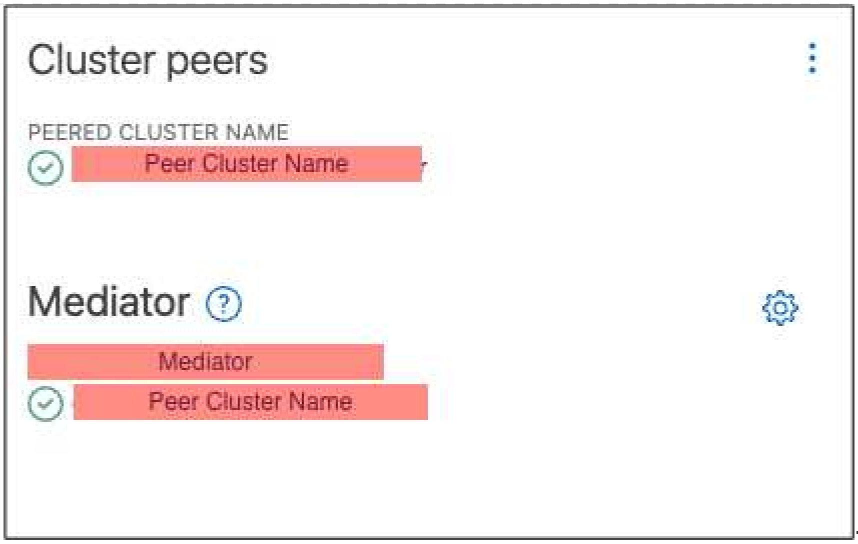
ONTAP Mediator 1.9 and later

1. Navigate to **Protection > Overview > Mediator > Configure**.
2. Select **Add**, and enter the following ONTAP Mediator information:
   - IPv4 address
   - Username
   - Password
   - Certificate
3. You can provide the Certificate input in two ways:
   - **Option (a)**: Select **Import** to navigate to the `intermediate.crt` file and import it.
   - **Option (b)**: Copy the content of the `intermediate.crt` file and paste it in the **Certificate** field.

     When all details are entered correctly, the provided certificate is installed on all the peer clusters.

     
     When the certificate addition is complete, ONTAP Mediator is added to the ONTAP cluster.

     The following image demonstrates a successful ONTAP Mediator configuration:



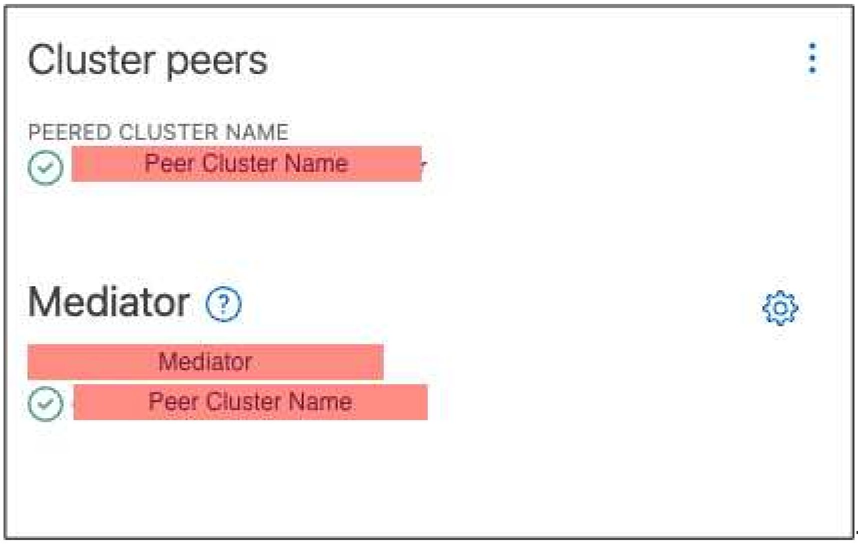
ONTAP Mediator 1.8 and earlier

1. Navigate to **Protection > Overview > Mediator > Configure**.
2. Select **Add**, and enter the following ONTAP Mediator information:
   - IPv4 address
   - Username
   - Password
   - Certificate
3. You can provide the Certificate input in two ways:
   - **Option (a)**: Select **Import** to navigate to the `ca.crt` file and import it.
   - **Option (b)**: Copy the content of the `ca.crt` file and paste it in the **Certificate** field.

     When all details are entered correctly, the provided certificate is installed on all the peer clusters.

     
     When the certificate addition is complete, ONTAP Mediator is added to the ONTAP cluster.

     The following image demonstrates a successful ONTAP Mediator configuration:



CLI

You can initialize ONTAP Mediator from either the primary or secondary cluster using the ONTAP CLI. When you issue the `mediator add` command on one cluster, ONTAP Mediator is automatically added on the other cluster.

When using ONTAP Mediator to monitor a SnapMirror active sync relationship, ONTAP Mediator cannot be initialized in ONTAP without a valid self-signed or certificate authority (CA) certificate. You add a valid certificate to the certificate store for peered clusters. When using ONTAP Mediator to monitor MetroCluster IP systems, HTTPS isn't used after the initial configuration; therefore, certificates aren't required.

ONTAP Mediator 1.9 and later

1. Find the ONTAP Mediator CA certificate from the ONTAP Mediator Linux VM/host software installation location `cd /opt/netapp/lib/ontap_mediator/ontap_mediator/server_config`.
2. Add a valid certificate authority to the certificate store on the peered cluster.

   Example:

   ```
   [root@ontap-mediator_config]# cat intermediate.crt
   -----BEGIN CERTIFICATE-----
   <certificate_value>
   -----END CERTIFICATE-----
   ```

3. Add the ONTAP Mediator CA certificate to an ONTAP cluster. When prompted, insert the CA certificate obtained from ONTAP Mediator. Repeat the steps on all of the peer clusters:

   `security certificate install -type server-ca -vserver <vserver_name>`

   Example:

   ```
   [root@ontap-mediator ~]# cd
   /opt/netapp/lib/ontap_mediator/ontap_mediator/server_config

   [root@ontap-mediator_config]# cat intermediate.crt
   -----BEGIN CERTIFICATE-----
   <certificate_value>
   -----END CERTIFICATE-----
   ```

```
C1_test_cluster::*> security certificate install -type server-ca
-vserver C1_test_cluster

Please enter Certificate: Press when done
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----

You should keep a copy of the CA-signed digital certificate for
future reference.

The installed certificate's CA and serial number for reference:
CA: ONTAP Mediator CA
serial: D86D8E4E87142XXX

The certificate's generated name for reference: ONTAPMediatorCA

C1_test_cluster::*>
```

4. View the self-signed CA certificate installed using the generated name of the certificate:

   ```
   security certificate show -common-name <common_name>
   ```

   Example:

   ```
   C1_test_cluster::*> security certificate show -common-name
   ONTAPMediatorCA
   Vserver    Serial Number   Certificate Name
   Type
   ---------- --------------- --------------------------------------
   ------------
   C1_test_cluster
              6BFD17DXXXXX7A71BB1F44D0326D2DEEXXXXX
                              ONTAPMediatorCA
   server-ca
       Certificate Authority: ONTAP Mediator CA
             Expiration Date: Thu Feb 15 14:35:25 2029
   ```

5. Initialize ONTAP Mediator on one of the clusters. ONTAP Mediator is automatically added for the other cluster:

   ```
   snapmirror mediator add -mediator-address <ip_address> -peer-cluster
   <peer_cluster_name> -username user_name
   ```

   Example:

```
C1_test_cluster::*> snapmirror mediator add -mediator-address
1.2.3.4 -peer-cluster C2_test_cluster -username mediatoradmin
Notice: Enter the mediator password.

Enter the password: ******
Enter the password again: ******
```

6. Optionally, check the job ID status `job show -id` to verify if the SnapMirror Mediator add command is successful.

   Example:

```
C1_test_cluster::*> snapmirror mediator show
This table is currently empty.

C1_test_cluster::*> snapmirror mediator add -peer-cluster
C2_test_cluster -type on-prem -mediator-address 1.2.3.4 -username
mediatoradmin

Notice: Enter the mediator password.

Enter the password:
Enter the password again:

Info: [Job: 87] 'mediator add' job queued

C1_test_cluster::*> job show -id 87
                            Owning
Job ID Name                 Vserver           Node           State
------ -------------------- ----------------- --------------
----------
87     mediator add         C1_test_cluster   C2_test        Running

Description: Creating a mediator entry

C1_test_cluster::*> job show -id 87
                            Owning
Job ID Name                 Vserver           Node           State
------ -------------------- ----------------- --------------
----------
87     mediator add         C1_test_cluster   C2_test        Success

Description: Creating a mediator entry

C1_test_cluster::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
Type
---------------- ---------------- ----------------- -------------
-------
1.2.3.4          C2_test_cluster  connected         true
on-prem

C1_test_cluster::*>
```

7. Check the status of the ONTAP Mediator configuration:

```
snapmirror mediator show
```

```
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
1.2.3.4          C2_test_cluster   connected        true
```

`Quorum Status` indicates whether the SnapMirror consistency group relationships are synchronized with ONTAP Mediator; a status of `true` indicates successful synchronization.

ONTAP Mediator 1.8 and earlier

1. Find the ONTAP Mediator CA certificate from the ONTAP Mediator Linux VM/host software installation location `cd /opt/netapp/lib/ontap_mediator/ontap_mediator/server_config`.
2. Add a valid certificate authority to the certificate store on the peered cluster.

   Example:

   ```
   [root@ontap-mediator_config]# cat ca.crt
   -----BEGIN CERTIFICATE-----
   <certificate_value>
   -----END CERTIFICATE-----
   ```

3. Add the ONTAP Mediator CA certificate to an ONTAP cluster. When prompted, insert the CA certificate obtained from the ONTAP Mediator. Repeat the steps on all of the peer clusters:

   `security certificate install -type server-ca -vserver <vserver_name>`

   Example:

   ```
   [root@ontap-mediator ~]# cd
   /opt/netapp/lib/ontap_mediator/ontap_mediator/server_config

   [root@ontap-mediator_config]# cat ca.crt
   -----BEGIN CERTIFICATE-----
   <certificate_value>
   -----END CERTIFICATE-----
   ```

```
C1_test_cluster::*> security certificate install -type server-ca
-vserver C1_test_cluster

Please enter Certificate: Press when done
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----

You should keep a copy of the CA-signed digital certificate for
future reference.

The installed certificate's CA and serial number for reference:
CA: ONTAP Mediator CA
serial: D86D8E4E87142XXX

The certificate's generated name for reference: ONTAPMediatorCA

C1_test_cluster::*>
```

4. View the self-signed CA certificate installed using the generated name of the certificate:

   `security certificate show -common-name <common_name>`

   Example:

```
C1_test_cluster::*> security certificate show -common-name
ONTAPMediatorCA
Vserver    Serial Number   Certificate Name
Type
---------- --------------- --------------------------------------
------------
C1_test_cluster
           6BFD17DXXXXX7A71BB1F44D0326D2DEEXXXXX
                           ONTAPMediatorCA
server-ca
    Certificate Authority: ONTAP Mediator CA
          Expiration Date: Thu Feb 15 14:35:25 2029
```

5. Initialize ONTAP Mediator on one of the clusters. ONTAP Mediator is automatically added for the other cluster:

   `snapmirror mediator add -mediator-address <ip_address> -peer-cluster <peer_cluster_name> -username user_name`

   Example:

```
C1_test_cluster::*> snapmirror mediator add -mediator-address
1.2.3.4 -peer-cluster C2_test_cluster -username mediatoradmin
Notice: Enter the mediator password.

Enter the password: ******
Enter the password again: ******
```

6. Optionally, check the job ID status `job show -id` to verify if the SnapMirror Mediator add command is successful.

   Example:

```
C1_test_cluster::*> snapmirror mediator show
This table is currently empty.

C1_test_cluster::*> snapmirror mediator add -peer-cluster
C2_test_cluster -type on-prem -mediator-address 1.2.3.4 -username
mediatoradmin

Notice: Enter the mediator password.

Enter the password:
Enter the password again:

Info: [Job: 87] 'mediator add' job queued

C1_test_cluster::*> job show -id 87
                            Owning
Job ID Name                 Vserver            Node           State
------ -------------------- ------------------ ---------------
----------
87     mediator add         C1_test_cluster   C2_test        Running

Description: Creating a mediator entry

C1_test_cluster::*> job show -id 87
                            Owning
Job ID Name                 Vserver            Node           State
------ -------------------- ------------------ ---------------
----------
87     mediator add         C1_test_cluster   C2_test        Success

Description: Creating a mediator entry

C1_test_cluster::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
Type
---------------- ---------------- ----------------- -------------
-------
1.2.3.4          C2_test_cluster  connected         true
on-prem

C1_test_cluster::*>
```

7. Check the status of the ONTAP Mediator configuration:

```
snapmirror mediator show
```

```
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
1.2.3.4          C2_test_cluster   connected         true
```

`Quorum Status` indicates whether the SnapMirror consistency group relationships are synchronized with ONTAP Mediator; a status of `true` indicates successful synchronization.

Re-initialize ONTAP Mediator with third-party certificates

You might need to re-initialize ONTAP Mediator. There might be situations that require the re-initialization of ONTAP Mediator such as a change in the ONTAP Mediator IP address, certificate expiration, and so on.

The following procedure illustrates the re-initialization of ONTAP Mediator for a specific case when a self-signed certificate needs to be replaced by a third-party certificate.

About this task

You need to replace the SnapMirror active sync cluster's self-signed certificates with third-party certificates, remove the ONTAP Mediator configuration from ONTAP, and then add ONTAP Mediator.

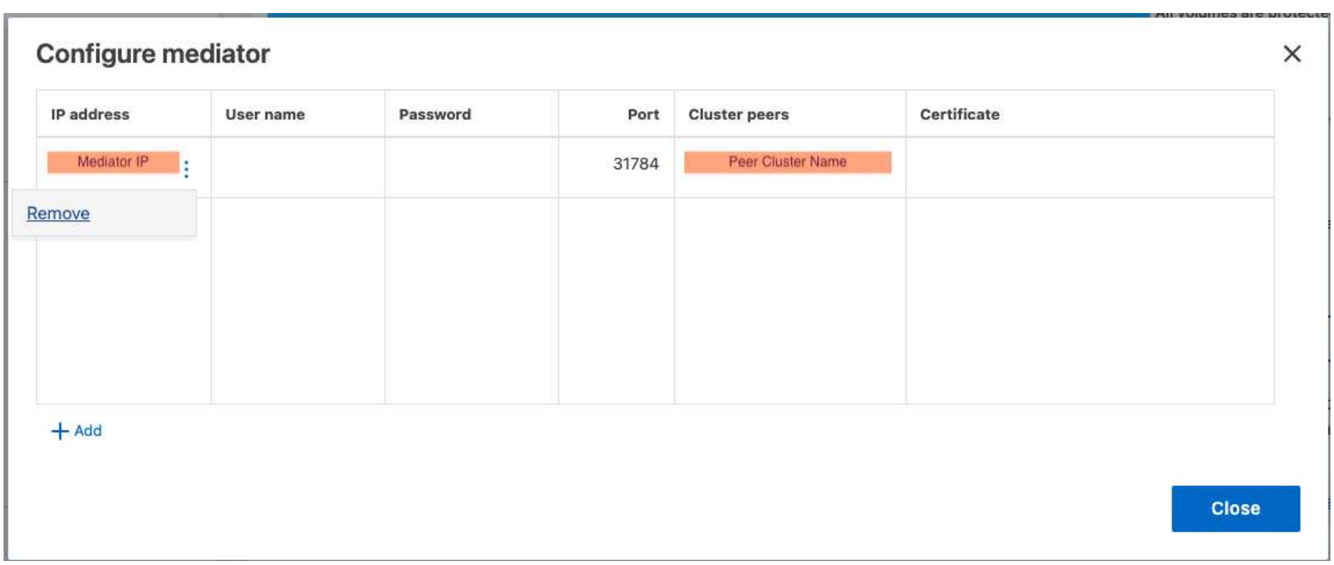
System Manager

With System Manager, you need to remove the ONTAP Mediator version configured with the old self-signed certificate from the ONTAP cluster and re-configure the ONTAP cluster with the new third-party certificate.

Steps

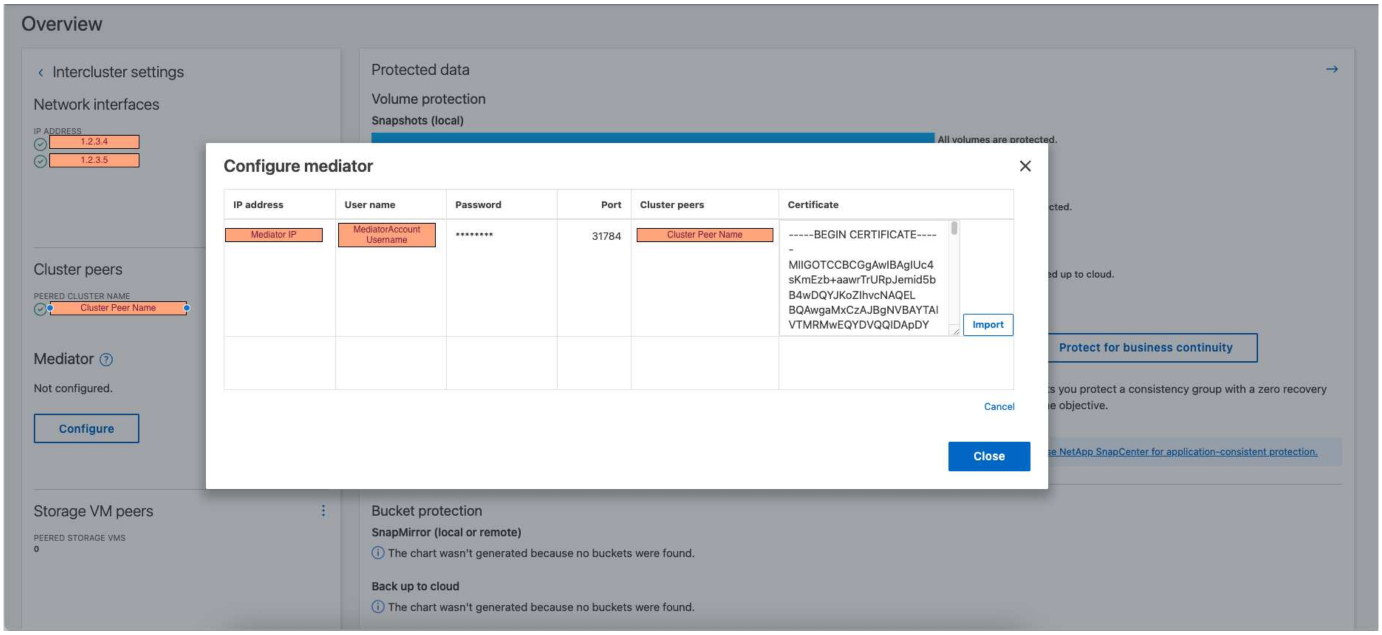
1. Select the menu options icon and select **Remove** to remove ONTAP Mediator.

   > ⓘ This step does not remove the self-signed server-ca from the ONTAP cluster. NetApp recommends navigating to the **Certificate** tab and removing it manually before performing the next step below to add a third-party certificate:



2. Add ONTAP Mediator again with the correct certificate.

ONTAP Mediator is now configured with the new third-party self-signed certificate.



CLI

You can re-initialize ONTAP Mediator from either the primary or secondary cluster by using the ONTAP CLI to replace the self-signed certificate with the third-party certificate.

ONTAP Mediator 1.9 and later

1. Remove the self-signed `intermediate.crt` installed earlier when you used self-signed certificates for all clusters. In the example below, there are two clusters:

   Example:

   ```
    C1_test_cluster::*> security certificate delete -vserver
   C1_test_cluster -common-name ONTAPMediatorCA
    2 entries were deleted.

    C2_test_cluster::*> security certificate delete -vserver
   C2_test_cluster -common-name ONTAPMediatorCA *
    2 entries were deleted.
   ```

2. Remove the previously configured ONTAP Mediator from the SnapMirror active sync cluster using `-force true`:

   Example:

   ```
   C1_test_cluster::*> snapmirror mediator show
   Mediator Address Peer Cluster     Connection Status Quorum Status
   ---------------- ---------------- ----------------- -------------
   1.2.3.4          C2_test_cluster   connected         true

   C1_test_cluster::*> snapmirror mediator remove -mediator-address
   1.2.3.4 -peer-cluster C2_test_cluster -force true

   Warning: You are trying to remove the ONTAP Mediator configuration
   with force. If this configuration exists on the peer cluster, it
   could lead to failure of a SnapMirror failover operation. Check if
   this configuration
            exists on the peer cluster C2_test_cluster and remove it as
   well.
   Do you want to continue? {y|n}: y

   Info: [Job 136] 'mediator remove' job queued

   C1_test_cluster::*> snapmirror mediator show
   This table is currently empty.
   ```

3. Refer to the steps described in Replace self-signed certificates with trusted third-party certificates for instructions on how to obtain certificates from a subordinate CA, referred to as `intermediate.crt`. Replace self-signed certificates with trusted third-party certificates

The `intermediate.crt` has certain properties that it derives from the request that need to be sent to the PKI authority, defined in the file `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/openssl_ca.cnf`

4. Add the new third-party ONTAP Mediator CA certificate `intermediate.crt` from the ONTAP Mediator Linux VM/host software installation location:

   Example:

```
[root@ontap-mediator ~]# cd
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config
[root@ontap-mediator_config]# cat intermediate.crt
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----
```

5. Add the `intermediate.crt` file to the peered cluster. Repeat this step for all peer clusters:

   Example:

```
C1_test_cluster::*> security certificate install -type server-ca
-vserver C1_test_cluster

Please enter Certificate: Press when done
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----

You should keep a copy of the CA-signed digital certificate for
future reference.

The installed certificate's CA and serial number for reference:
CA: ONTAP Mediator CA
serial: D86D8E4E87142XXX

The certificate's generated name for reference: ONTAPMediatorCA

C1_test_cluster::*>
```

6. Remove the previously configured ONTAP Mediator from the SnapMirror active sync cluster:

   Example:

```
C1_test_cluster::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
1.2.3.4          C2_test_cluster  connected         true

C1_test_cluster::*> snapmirror mediator remove -mediator-address
1.2.3.4 -peer-cluster C2_test_cluster

Info: [Job 86] 'mediator remove' job queued
C1_test_cluster::*> snapmirror mediator show
This table is currently empty.
```

7. Add ONTAP Mediator again:

   Example:

```
C1_test_cluster::*> snapmirror mediator add -mediator-address
1.2.3.4 -peer-cluster C2_test_cluster -username mediatoradmin

Notice: Enter the mediator password.

Enter the password:
Enter the password again:

Info: [Job: 87] 'mediator add' job queued

C1_test_cluster::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
1.2.3.4          C2_test_cluster  connected         true
```

   `Quorum Status` indicates whether the SnapMirror consistency group relationships are synchronized with the mediator; a status of `true` indicates successful synchronization.

ONTAP Mediator 1.8 and earlier

1. Remove the self-signed `ca.crt` installed earlier when you used self-signed certificates for all clusters. In the example below, there are two clusters:

   Example:

```
 C1_test_cluster::*> security certificate delete -vserver
C1_test_cluster -common-name ONTAPMediatorCA
 2 entries were deleted.

 C2_test_cluster::*> security certificate delete -vserver
C2_test_cluster -common-name ONTAPMediatorCA *
 2 entries were deleted.
```

2. Remove the previously configured ONTAP Mediator from the SnapMirror active sync cluster using `-force true`:

   Example:

```
C1_test_cluster::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
1.2.3.4          C2_test_cluster   connected         true

C1_test_cluster::*> snapmirror mediator remove -mediator-address
1.2.3.4 -peer-cluster C2_test_cluster -force true

Warning: You are trying to remove the ONTAP Mediator configuration
with force. If this configuration exists on the peer cluster, it
could lead to failure of a SnapMirror failover operation. Check if
this configuration
         exists on the peer cluster C2_test_cluster and remove it as
well.
Do you want to continue? {y|n}: y

Info: [Job 136] 'mediator remove' job queued

C1_test_cluster::*> snapmirror mediator show
This table is currently empty.
```

3. Refer to the steps described in Replace self-signed certificates with trusted third-party certificates for instructions on how to obtain certificates from a subordinate CA, referred to as `ca.crt`.
   Replace self-signed certificates with trusted third-party certificates

   > The `ca.crt` has certain properties that it derives from the request that need to be sent to the PKI authority, defined in the file `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/openssl_ca.cnf`

4. Add the new third-party ONTAP Mediator CA certificate `ca.crt` from the ONTAP Mediator Linux VM/host software installation location:

Example:

```
[root@ontap-mediator ~]# cd
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config
[root@ontap-mediator_config]# cat ca.crt
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----
```

5. Add the `intermediate.crt` file to the peered cluster. Repeat this step for all peer clusters:

   Example:

```
C1_test_cluster::*> security certificate install -type server-ca
-vserver C1_test_cluster

Please enter Certificate: Press when done
-----BEGIN CERTIFICATE-----
<certificate_value>
-----END CERTIFICATE-----

You should keep a copy of the CA-signed digital certificate for
future reference.

The installed certificate's CA and serial number for reference:
CA: ONTAP Mediator CA
serial: D86D8E4E87142XXX

The certificate's generated name for reference: ONTAPMediatorCA

C1_test_cluster::*>
```

6. Remove the previously configured ONTAP Mediator from the SnapMirror active sync cluster:

   Example:

```
C1_test_cluster::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
1.2.3.4          C2_test_cluster  connected         true

C1_test_cluster::*> snapmirror mediator remove -mediator-address
1.2.3.4 -peer-cluster C2_test_cluster

Info: [Job 86] 'mediator remove' job queued
C1_test_cluster::*> snapmirror mediator show
This table is currently empty.
```

7. Add ONTAP Mediator again:

   Example:

```
C1_test_cluster::*> snapmirror mediator add -mediator-address
1.2.3.4 -peer-cluster C2_test_cluster -username mediatoradmin

Notice: Enter the mediator password.

Enter the password:
Enter the password again:

Info: [Job: 87] 'mediator add' job queued

C1_test_cluster::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
1.2.3.4          C2_test_cluster  connected         true
```

   `Quorum Status` indicates whether the SnapMirror consistency group relationships are synchronized with the mediator; a status of `true` indicates successful synchronization.

Prepare to configure ONTAP Cloud Mediator

Before you configure ONTAP Cloud Mediator, you must ensure that the prerequisites are met.

Firewall requirements

The firewall setting on the domain controller must allow HTTPS traffic to `api.bluexp.netapp.com` from both clusters.

Proxy server requirements

If you use proxy servers for SnapMirror active sync, ensure the proxy servers are created and you have the following proxy server information:

- HTTPS proxy IP
- Port
- Username
- Password

Latency

The recommended ping latency between the BlueXP cloud server and SnapMirror active sync cluster peers is less than 200 ms.

Root CA certificates

Check the cluster for certificates

ONTAP comes with well-known root CA certificates pre-installed so in most cases you do not need to install the BlueXP server's root CA certificate. Before you begin the ONTAP Cloud Mediator configuration, you can check the cluster to verify that the certificates exist:

Example:

```
C1_cluster% openssl s_client -showcerts -connect
api.bluexp.netapp.com:443|egrep "s:|i:"
depth=2 C = US, O = DigiCert Inc, OU = www.digicert.com, CN = DigiCert
Global Root G2
verify return:1
depth=1 C = US, O = Microsoft Corporation, CN = Microsoft Azure RSA TLS
Issuing CA 04
verify return:1
depth=0 C = US, ST = WA, L = Redmond, O = Microsoft Corporation, CN =
*.azureedge.net
verify return:1
 0 s:/C=US/ST=WA/L=Redmond/O=Microsoft Corporation/CN=*.azureedge.net
   i:/C=US/O=Microsoft Corporation/CN=Microsoft Azure RSA TLS Issuing CA
04
 1 s:/C=US/O=Microsoft Corporation/CN=Microsoft Azure RSA TLS Issuing CA
```

```
04
   i:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2
 2 s:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2
   i:/C=US/O=DigiCert Inc/OU=www.digicert.com/CN=DigiCert Global Root G2
<====

C1_cluster::> security certificate show -common-name DigiCert*

ca
    Certificate Authority: DigiCert Trusted Root G4
          Expiration Date: Fri Jan 15 17:30:00 2038
```

Check proxy server for installed certificates

If you are using a proxy to connect to the ONTAP Cloud Mediator service in BlueXP, ensure that the proxy server's root CA certificates are installed in ONTAP:

Example:

```
C1_cluster% openssl s_client -showcerts -proxy <ip:port> -connect
api.bluexp.netapp.com:443 |egrep "s:|i:"
```

Download the CA certificate:

If necessary, you can download the root-CA certificates fom the certificate authority's website and install them on the clusters.

Example:

```
C1_cluster::> security certificate install -type server-ca -vserver
C1_cluster

C2_cluster::> security certificate install -type server-ca -vserver
C2_cluster
```

Configure the ONTAP Cloud Mediator for SnapMirror active sync

Beginning with ONTAP 9.17.1, you can use ONTAP Cloud Mediator to enable business continuity by monitoring the health of each cluster. ONTAP Cloud Mediator is a cloud-based service. When you use ONTAP Cloud Mediator with SnapMirror active sync, you must first confirm that BlueXP services and client information are configured and ensure proper cluster peering.

As with ONTAP Mediator, ONTAP Cloud Mediator provides a persistent and fenced store for high availability (HA) metadata used by the ONTAP clusters in a SnapMirror active sync relationship. ONTAP Cloud Mediator provides a synchronous node health query functionality to aid in quorum determination and serves as a ping proxy for controller liveliness detection.

Before you begin

Before you configure ONTAP Cloud Mediator, you should confirm the following information:

* The cluster is configured.

  Configure ONTAP clusters for SnapMirror active sync

* You have a valid BlueXP subscription.

  Subscribe to BlueXP data services (standard mode)

* You have copied your BlueXP organization ID from the BlueXP console and created a BlueXP member service account to use when you configure ONTAP Cloud Mediator. When you create the service account, the organization must be set to the subscription where you configured the ONTAP Cloud Mediator. The category must be set to **Application**, and the role type must be **ONTAP Mediator Setup Role**. You must

save the client ID and client secret when you create the role.

Add BlueXP members and service accounts

Steps

You can add ONTAP Cloud Mediator using System Manager or the ONTAP CLI.

System Manager

1. Navigate to **Protection > Overview > Mediator** and select **Add**.
2. In the **Add a mediator** window, select **Cloud** as the mediator type and enter the following information:
   - BlueXP organization ID
   - BlueXP client ID
   - BlueXP client secret
3. Select the cluster peer.
4. If you are using an HTTP proxy and it's not already configured, enter the HTTP proxy information for the local and remote hosts.

   It's recommended that you use a different proxy server for each cluster peer.
5. Optional: If a root CA certificate needs to be installed in ONTAP, especially when using a proxy server, paste the certificate in the text box provided.
6. Select **Add**.
7. Navigate to **Protection > Overview** and check the status of the relationship between the SnapMirror active sync clusters and ONTAP Cloud Mediator.

CLI

1. Configure ONTAP Cloud Mediator:
   `snapmirror mediator add -peer-cluster <peerClusterName> -type cloud -bluexp -org-id <BlueXP Organization ID> -service-account-client-id <Service Account Client ID> -use-http-proxy-local <true|false> -use-http-proxy -remote <true|false>`
2. Check ONTAP Cloud Mediator status:
   `snapmirror mediator show`

   Example:

```
C1_cluster::> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
Type
---------------- ---------------- ----------------- -------------
-------
0.0.0.0          C2_cluster       connected         true
cloud
```

Protect with ONTAP SnapMirror active sync

SnapMirror active sync offers asymmetric protection and, beginning with ONTAP 9.15.1, symmetric active/active protection.

Configure asymmetric protection

Configuring asymmetric protection using SnapMirror active sync involves selecting LUNs on the ONTAP source cluster and adding them to a consistency group.

Before you begin

- You must have a SnapMirror synchronous license.
- You must be a cluster or storage VM administrator.
- All constituent volumes in a consistency group must be in a single storage VM (SVM).
  - LUNs can reside on different volumes.
- The source and destination cluster cannot be the same.
- You cannot establish SnapMirror active sync consistency group relationships across ASA clusters and non-ASA clusters.
- The default IPspace is required by SnapMirror active sync for cluster peer relationships. Custom IPspace is not supported.
- The name of the consistency group must be unique.
- The volumes on the secondary (destination) cluster must be type DP.
- The primary and the secondary SVMs must be in a peered relationship.

Steps

You can configure a consistency group using the ONTAP CLI or System Manager.

Beginning with ONTAP 9.10.1, ONTAP offers a consistency group endpoint and menu in System Manager, offering additional management utilities. If you are using ONTAP 9.10.1 or later, see Configure a consistency group then configure protection to create a SnapMirror active sync relationship.

> From ONTAP 9.14.1 through 9.8, SnapMirror active sync is referred to as SnapMirror Business Continuity (SM-BC).

System Manager

1. On the primary cluster, navigate to **Protection > Overview > Protect for Business Continuity > Protect LUNs**.
2. Select the LUNs you want to protect and add them to a protection group.
3. Select the destination cluster and SVM.
4. **Initialize relationship** is selected by default. Click **Save** to begin protection.
5. Go to **Dashboard > Performance** to verify IOPS activity for the LUNs.
6. On the destination cluster, use System Manager to verify that the protection for business continuity relationship is in sync: **Protection > Relationships**.

CLI

1. Create a consistency group relationship from the destination cluster.
   `destination::> snapmirror create -source-path` *`source-path`* `-destination-path` *`destination-path`* `-cg-item-mappings` *`volume-paths`* `-policy` *`policy-name`*

   You can map up to 12 constituent volumes using the `cg-item-mappings` parameter on the `snapmirror create` command.

   The following example creates two consistency groups: `cg_src_ on the source with `vol1` and `vol2` and a mirrored destination consistency group, `cg_dst`.

   ```
   destination::> snapmirror create -source-path vs1_src:/cg/cg_src
   -destination-path vs1_dst:/cg/cg_dst -cg-item-mappings
   vol_src1:@vol_dst1,vol_src2:@vol_dst2 -policy AutomatedFailOver
   ```

2. From the destination cluster, initialize the consistency group.

   ```
   destination::>snapmirror initialize -destination-path destination-
   consistency-group
   ```

3. Confirm that the initialization operation completed successfully. The status should be `InSync`.

   ```
   snapmirror show
   ```

4. On each cluster, create an igroup so you can map LUNs to the initiator on the application host.
   `lun igroup create -igroup` *`name`* `-protocol` *`fcp|iscsi`* `-ostype` *`os`* `-initiator` *`initiator_name`*

   Learn more about `lun igroup create` in the ONTAP command reference.

5. On each cluster, map LUNs to the igroup:

   ```
   lun map -path path_name -igroup igroup_name
   ```

6. Verify the LUN mapping completed successfully with the `lun map` command. Then, you can discover the new LUNs on the application host.

Configure symmetric active/active protection

You can establish symmetric protection using System Manager or the ONTAP CLI. In both interfaces, there are different steps for uniform and non-uniform configurations.

Before you begin

* Both clusters must be running ONTAP 9.15.1 or later.
* Symmetric active/active configurations require the `AutomatedFailoverDuplex` protection policy. Alternately, you can create a custom SnapMirror policy provided the `-type` is `automated-failover-duplex`.
* In ONTAP 9.15.1, symmetric active/active is only supported on 2-node clusters.
* Beginning with ONTAP 9.16.1 GA, SnapMirror active sync supports symmetric active/active configurations on four-node clusters.
    * To use SnapMirror active sync on a four-node cluster, you must be running ONTAP 9.16.1 GA or later.
    * Before deploying a four-node configuration, you must create a cluster peer relationship.
    * Review the limits for four-node clusters.
    * If you revert to a two-node cluster, you must remove the SnapMirror active sync relationships from the cluster before reverting.
    * You can use the four-node configuration to upgrade storage and controllers. This process is non-disruptive and expands the cluster while moving volumes into the new nodes. For more information, see refresh a cluster.
* Beginning with ONTAP 9.17.1, you can configure symmetric active/active protection on NVMe namespaces only when both clusters are running ONTAP 9.17.1 or later.

Configure symmetric active/active protection using a SCSI SnapMirror active sync configuration

Steps

You can use System Manager or the ONTAP CLI to configure symmetric active/active protection using SCSI protocol host mappings.

System Manager

Steps for a uniform configuration

1. On the primary site, create a consistency group using new LUNs.
   a. When creating the consistency group, specify host initiators to create igroups.
   b. Select the checkbox to **Enable SnapMirror** then choose the `AutomatedFailoverDuplex` policy.
   c. In the dialog box that appears, select the **Replicate initiator groups** checkbox to replicate igroups. In **Edit proximity settings**, set proximal SVMs for your hosts.
   d. Select **Save**.

Steps for a non-uniform configuration

1. On the primary site, create a consistency group using new LUNs.
   a. When creating the consistency group, specify host initiators to create igroups.
   b. Select the checkbox to **Enable SnapMirror** then choose the `AutomatedFailoverDuplex` policy.
   c. Select **Save** to create the LUNs, consistency group, igroup, SnapMirror relationship, and igroup mapping.
2. On the secondary site, create an igroup and map the LUNs.
   a. Navigate to **Hosts** > **SAN Initiator Groups**.
   b. Select **+Add** to create a new igroup.
   c. Provide a **Name**, select the **Host Operating System**, then choose **Initiator Group Members**.
   d. Select **Save** to initialize the relationship.
3. Map the new igroup to the destination LUNs.
   a. Navigate to **Storage** > **LUNs**.
   b. Select all the LUNs to map to the igroup.
   c. Select **More** then **Map to Initiator Groups**.

CLI

Steps for a uniform configuration

1. Create a new SnapMirror relationship grouping all the volumes in the application. Ensure you designate the `AutomatedFailOverDuplex` policy to establish bidirectional sync replication.

   ```
   snapmirror create -source-path <source_path> -destination-path
   <destination_path> -cg-item-mappings <source_volume:@destination_volume>
   -policy AutomatedFailOverDuplex
   ```

   Example:
   The following example creates two consistency groups: cg_src on the source with vol1 and vol2, and a mirrored consistency group on the destination, cg_dst.

```
destination::> snapmirror create -source-path vs1_src:/cg/cg_src
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings
vol_src1:@vol_dst1,vol_src2:@vol_dst2 -policy AutomatedFailOver
```

2. Initialize the SnapMirror relationship:
`snapmirror initialize -destination-path <destination-consistency-group>`
3. Confirm the operation has succeeded by waiting for the `Mirrored State` to show as `SnapMirrored` and the `Relationship Status` as `Insync`.

```
snapmirror show -destination-path <destination_path>
```

4. On your host, configure host connectivity with access to each cluster according to your needs.
5. Establish the igroup configuration. Set the preferred paths for initiators on the local cluster. Specify the option to replicate the configuration to the peer cluster for inverse affinity.

```
SiteA::> igroup create -vserver <svm_name> -ostype <os_type> -igroup
<igroup_name> -replication-peer <peer_svm_name> -initiator <host>
```

> Beginning with ONTAP 9.16.1, use the `-proximal-vserver local` parameter in this command.

```
SiteA::> igroup add -vserver <svm_name> -igroup <igroup_name> -ostype
<os_type> -initiator <host>
```

> Beginning with ONTAP 9.16.1, use the `-proximal-vserver peer` parameter in this command.

6. From the host, discover the paths and verify the hosts have an active/optimized path to the storage LUN from the preferred cluster.
7. Deploy the application and distribute the VM workloads across clusters to achieve the required load balancing.

Steps for a non-uniform configuration

1. Create a new SnapMirror relationship grouping all the volumes in the application. Ensure you designate the `AutomatedFailOverDuplex` policy to establish bidirectional sync replication.

```
snapmirror create -source-path <source_path> -destination-path
<destination_path> -cg-item-mappings <source_volume:@destination_volume>
-policy AutomatedFailOverDuplex
```

Example:
The following example creates two consistency groups: cg_src on the source with vol1 and vol2, and a mirrored consistency group on the destination, cg_dst.

```
destination::> snapmirror create -source-path vs1_src:/cg/cg_src
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings
vol_src1:@vol_dst1,vol_src2:@vol_dst2 -policy AutomatedFailOver
```

2. Initialize the SnapMirror relationship:
   `snapmirror initialize -destination-path <destination-consistency-group>`
3. Confirm the operation has succeeded by waiting for the `Mirrored State` to show as `SnapMirrored` and the `Relationship Status` as `Insync`.

   ```
   snapmirror show -destination-path <destination_path>
   ```

4. On your host, configure host connectivity with access to each cluster according to your needs.
5. Establish the igroup configurations on both the source and destination clusters.

   ```
   # primary site
   SiteA::> igroup create -vserver <svm_name> -igroup <igroup_name> -initiator
   <host_1_name_>

   # secondary site
   SiteB::> igroup create -vserver <svm_name> -igroup <igroup_name> -initiator
   <host_2_name>
   ```

6. From the host, discover the paths and verify the hosts have an active/optimized path to the storage LUN from the preferred cluster.
7. Deploy the application and distribute the VM workloads across clusters to achieve the required load balancing.

Configure symmetric active/active protection using an NVMe SnapMirror active sync configuration

Before you begin

In addition to the requirements for configuring symmetric active/active protection, you should be aware of the supported and unsupported configurations when using the NVMe protocol.

- Consistency groups can have one or more subsystem.
- Volumes within the consistency group can have namespace maps from multiple subsystems.
- Subsystems cannot have namespace maps that belong to more than one consistency group.
- Subsystems cannot have some namespace maps that belong to a consistency group and some namespace maps that do not belong to a consistency group.
- Subsystems must have namespace maps that are part of the same consistency group.

Steps

Beginning with ONTAP 9.17.1, you can use System Manager or the ONTAP CLI to create a consistency group and configure symmetric active/active protection using NVMe protocol host mappings.

System Manager

1. On the primary site, create a consistency group using new volumes or NVMe namespaces.
2. select **+Add** and choose **Using new NVMe namespaces**.
3. Enter the consistency group name.
4. Select **More**.
5. In the **Protection** section, select **Enable SnapMirror** then choose the `AutomatedFailoverDuplex` policy.
6. In the **Host mapping** section, choose either **Existing NVMe subsystem** or **New NVMe subsystem**.
7. Select **In proximity to** to change the proximal SVM. The source SVM is selected by default.
8. If necessary, add another NVMe subsystem.

CLI

1. Create a new SnapMirror relationship grouping all the volumes containing all NVMe namespaces used by the application. Ensure you designate the `AutomatedFailOverDuplex` policy to establish bidirectional sync replication.

   `snapmirror create -source-path <source_path> -destination-path <destination_path> -cg-item-mappings <source_volume:@destination_volume> -policy AutomatedFailOverDuplex`

   Example:

   ```
   DST::> snapmirror create -source-path vs_src:/cg/cg_src_1
   -destination-path vs_dst:/cg/cg_dst_1 -cg-item-mappings
   vs_src_vol1:@vs_dst_vol1,vs_src_vol2:@vs_dst_vol2 -policy
   AutomatedFailOverDuplex
   ```

2. Initialize the SnapMirror relationship:
   `snapmirror initialize -destination-path <destination-consistency-group>`

   Example:

   ```
   DST::> snapmirror initialize -destination-path vs1:/cg/cg_dst_1
   ```

3. Confirm the operation has succeeded by waiting for the `Mirrored State` to show as `SnapMirrored` and the `Relationship Status` as `Insync`.

   `snapmirror show -destination-path <destination_path>`

   The NVMe subsystems associated with the NVMe namespaces in the primary volumes are automatically replicated to the secondary cluster.

4. On your host, configure host connectivity with access to each cluster according to your needs.
5. Specify the SVM that is proximal to each of your hosts. This enables host access to the NVMe namespace using a path from the preferred cluster. This might be the SVM in the primary cluster *or*

the SVM in DR cluster.

The following command indicates that SVM VS_A is proximal to host H1 and set VS_A as the proximal SVM:

```
SiteA::> vserver nvme subsystem host add -subsystem ss1 -host-nqn <H1_NQN>
-proximal-vservers <VS_A>
```

The following command indicates that SVM VS_B is proximal to host H2 and sets VS_B as the proximal SVM:

```
SiteB::> vserver nvme subsystem host add -subsystem ss1 -host-nqn <H2_NQN>
-proximal-vservers <VS_B>
```

6. From the host, discover the paths and verify the hosts have an active/optimized path to the storage from the preferred cluster.
7. Deploy the application and distribute the VM workloads across clusters to achieve the required load balancing.

- snapmirror show

Convert an existing ONTAP SnapMirror relationship to SnapMirror active sync relationship

If you've configured SnapMirror protection, you can convert the relationship to SnapMirror active sync. Beginning with ONTAP 9.15.1, you can convert the relationship to use symmetric active/active protection.

Convert an existing iSCSI or FC SnapMirror relationship to an asymmetric SnapMirror active sync relationship

If you have an existing iSCSI or FC SnapMirror synchronous relationship between a source and destination cluster, you can convert it to an asymmetric SnapMirror active sync relationship. This allows you to associate the mirrored volumes with a consistency group, ensuring zero RPO across a multi-volume workload. Additionally, you can retain existing SnapMirror snapshots if you need to revert to a point in time prior to establishing the SnapMirror active sync relationship.

About this task

- You must be a cluster and SVM administrator on the primary and secondary clusters.
- You cannot convert zero RPO to zero RTO sync by changing the SnapMirror policy.
- You must ensure the LUNs are unmapped before issuing the `snapmirror create` command.

  If existing LUNs on the secondary volume are mapped and the `AutomatedFailover` policy is configured, the `snapmirror create` command triggers an error.

Before you begin

- A zero RPO SnapMirror synchrnous relationship must exist between the primary and secondary cluster.
- All LUNs on the destination volume must be unmapped before the zero RTO SnapMirror relationship can

be created.

- SnapMirror active sync only supports SAN protocols (not NFS/CIFS). Ensure no constituent of the consistency group is mounted for NAS access.

Steps

1. From the secondary cluster, perform a SnapMirror update on the existing relationship:

   ```
   SiteB::>snapmirror update -destination-path vs1_dst:vol1
   ```

2. Verify that the SnapMirror update completed successfully:

   ```
   SiteB::>snapmirror show
   ```

3. Pause each of the zero RPO synchronous relationships:

   ```
   SiteB::>snapmirror quiesce -destination-path vs1_dst:vol1

   SiteB::>snapmirror quiesce -destination-path vs1_dst:vol2
   ```

4. Delete each of the zero RPO synchronous relationships:

   ```
   SiteB::>snapmirror delete -destination-path vs1_dst:vol1

   SiteB::>snapmirror delete -destination-path vs1_dst:vol2
   ```

5. Release the source SnapMirror relationship but retain the common snapshots:

   ```
   SiteA::>snapmirror release -relationship-info-only true -destination-path
   vs1_dst:vol1

   SiteA::>snapmirror release -relationship-info-only true -destination-path
   vs1_dst:vol2
   ```

6. Create a zero RTO SnapMirror synchronous relationship:

   ```
   SiteB::> snapmirror create -source-path vs1_src:/cg/cg_src -destination-path
   vs1_dst:/cg/cg_dst -cg-item-mappings vol1:@vol1,vol2:@vol2 -policy
   AutomatedFailover
   ```

7. Resynchronize the consistency group:

   ```
   SiteB::> snapmirror resync -destination-path vs1_dst:/cg/cg_dst
   ```

8. Rescan host LUN I/O paths to restore all paths to the LUNs.

Convert an existing iSCSI or FC SnapMirror relationship to symmetric active/active

Beginning with ONTAP 9.15.1, you can convert an existing iSCSI or FC SnapMirror relationship to a SnapMirror active sync symmetric active/active relationship.

Before you begin

- You must be running ONTAP 9.15.1 or later.
- A zero RPO SnapMirror synchrnous relationship must exist between the primary and secondary cluster.

* All LUNs on the destination volume must be unmapped before the zero RTO SnapMirror relationship can be created.
* SnapMirror active sync only supports SAN protocols (not NFS/CIFS). Ensure no constituent of the consistency group is mounted for NAS access.

Steps

1. From the secondary cluster, perform a SnapMirror update on the existing relationship:

   ```
   SiteB::>snapmirror update -destination-path vs1_dst:vol1
   ```

2. Verify that the SnapMirror update completed successfully:

   ```
   SiteB::>snapmirror show
   ```

3. Pause each of the zero RPO synchronous relationships:

   ```
   SiteB::>snapmirror quiesce -destination-path vs1_dst:vol1
   ```

   ```
   SiteB::>snapmirror quiesce -destination-path vs1_dst:vol2
   ```

4. Delete each of the zero RPO synchronous relationships:

   ```
   SiteB::>snapmirror delete -destination-path vs1_dst:vol1
   ```

   ```
   SiteB::>snapmirror delete -destination-path vs1_dst:vol2
   ```

5. Release the source SnapMirror relationship but retain the common snapshots:

   ```
   SiteA::>snapmirror release -relationship-info-only true -destination-path
   vs1_dst:vol1
   ```

   ```
   SiteA::>snapmirror release -relationship-info-only true -destination-path
   vs1_dst:vol2
   ```

6. Create a zero RTO SnapMirror synchronous relationship with the AutomatedFailoverDuplex policy:

   ```
   SiteB::> snapmirror create -source-path vs1_src:/cg/cg_src -destination-path
   vs1_dst:/cg/cg_dst -cg-item-mappings vol1:@vol1,vol2:@vol2 -policy
   AutomatedFailoverDuplex
   ```

7. If the existing hosts are local the primary cluster, add the host to the secondary cluster and establish connectivity with respective access to each cluster.
8. On the secondary site, delete the LUN maps on the igroups associated with remote hosts.

   > Ensure the igroup does not contain maps for non-replicated LUNs.

   ```
   SiteB::> lun mapping delete -vserver <svm_name> -igroup <igroup> -path <>
   ```

9. On the primary site, modify the initiator configuration for existing hosts to set the proximal path for initiators on the local cluster.

   ```
   SiteA::> igroup initiator add-proximal-vserver -vserver <svm_name> -initiator
   ```

```
<host> -proximal-vserver <server>
```

10. Add a new igroup and initiator for the new hosts and set the host proximity for host affinity to its local site. Ennable igroup replication to replicate the configuration and invert the host locality on the remote cluster.

```
SiteA::> igroup modify -vserver vsA -igroup ig1 -replication-peer vsB
SiteA::> igroup initiator add-proximal-vserver -vserver vsA -initiator host2
-proximal-vserver vsB
```

11. Discover the paths on the hosts and verify the hosts have an Active/Optimized path to the storage LUN from the preferred cluster
12. Deploy the application and distribute the VM workloads across clusters.
13. Resynchronize the consistency group:

```
SiteB::> snapmirror resync -destination-path vs1_dst:/cg/cg_dst
```

14. Rescan host LUN I/O paths to restore all paths to the LUNs.

- snapmirror show

Convert ONTAP SnapMirror active sync relationship type

Beginning with ONTAP 9.15.1, you can convert between types of SnapMirror active sync protection: from asymmetric to symmetric active/active and vice versa.

Convert to a symmetric active/active relationship

You can convert a iSCSI or FC SnapMirror active sync relationship with asymmetric protection to use symmetric active/active.

Before you begin

- Both clusters must be running ONTAP 9.15.1 or later.
- Symmetric active/active configurations require the `AutomatedFailoverDuplex` protection policy. Alternately, you can create a custom SnapMirror policy provided the `-type` is `automated-failover-duplex`.

System Manager

Steps for a uniform configuration

1. Remove the destination igroup:
   a. On the destination cluster, navigate to **Hosts** > **SAN Initiator Groups**.
   b. Select the igroup with the SnapMirror relationship, then **Delete**.
   c. In the dialog box, select the **Unmap the associated LUNs** box then **Delete**.
2. Edit the SnapMirror active sync relationship.
   a. Navigate to **Protection** > **Relationships**.
   b. Select the kabob menu next to the relationship you want to modify then **Edit**.
   c. Modify the **Protection Policy** to AutomatedFailoverDuplex.
   d. Selecting `AutoMatedFailoverDuplex` prompts a dialog box to modify host proximity settings. For the initiators, select the appropriate option for **Initiator proximal to** then **Save**.
   e. Select **Save**.
3. In the **Protection** menu, confirm the operation succeeded when the relationship displays as `InSync`.

Steps for a non-uniform configuration

1. Remove the destination igroup:
   a. On the secondary site, navigate to **Hosts** > **SAN Initiator Groups**.
   b. Select the igroup with the SnapMirror relationship, then **Delete**.
   c. In the dialog box, select the **Unmap the associated LUNs** box then **Delete**.
2. Create a new igroup:
   a. In the **SAN Initiator Groups** menu on the destination site, select **Add**.
   b. Provide a **Name**, select the **Host Operating System**, then choose **Initiator Group Members**.
   c. Select **Save**.
3. Map the new igroup to the destination LUNs.
   a. Navigate to **Storage** > **LUNs**.
   b. Select all the LUNs to map to the igroup.
   c. Select **More** then **Map to Initiator Groups**.
4. Edit the SnapMirror active sync relationship.
   a. Navigate to **Protection** > **Relationships**.
   b. Select the kabob menu next to the relationship you want to modify then **Edit**.
   c. Modify the **Protection Policy** to AutomatedFailoverDuplex.
   d. Selecting AutoMatedFailoverDuplex initiates the option to modify host proximity settings. For the initiators, select the appropriate option for **Initiator proximal to** then **Save**.
   e. Select **Save**.
5. In the **Protection** menu, confirm the operation succeeded when the relationship displays as `InSync`.

CLI

Steps for a uniform configuration

1. Modify the SnapMirror policy from `AutomatedFailover` to `AutomatedFailoverDuplex`:

```
snapmirror modify -destination-path <destination_path> -policy
AutomatedFailoverDuplex
```

2. Modifying the policy triggers a resync. Wait for the resync to complete and confirm the relationship is `Insync`:

```
snapmirror show -destination-path <destination_path>
```

3. If the existing hosts are local the primary cluster, add the host to the second cluster and establish connectivity with respective access to each cluster.
4. On the secondary site, delete the LUN maps on the igroups associated with remote hosts.

   Ensure the igroup does not contain maps for non-replicated LUNs.

```
SiteB::> lun mapping delete -vserver <svm_name> -igroup <igroup> -path <>
```

5. On the primary site, set the privilege level to `advanced`:

```
SiteA::> set -privilege advanced
```

6. Modify the initiator configuration for existing hosts to set the proximal path for initiators on the local cluster.

```
SiteA::*> igroup initiator add-proximal-vserver -vserver <svm_name>
-initiator <host> -proximal-vserver <server>
```

   You can set the privilege level back to admin after you complete this step.

7. Add a new igroup and initiator for the new hosts and set the host proximity for host affinity to its local site. Ennable igroup replication to replicate the configuration and invert the host locality on the remote cluster.

```
SiteA::> igroup modify -vserver vsA -igroup ig1 -replication-peer vsB
SiteA::> igroup initiator add-proximal-vserver -vserver vsA -initiator
host2 -proximal-vserver vsB
```

8. Discover the paths on the hosts and verify the hosts have an Active/Optimized path to the storage LUN from the preferred cluster
9. Deploy the application and distribute the VM workloads across clusters.

Steps for a non-uniform configuration

1. Modify the SnapMirror policy from `AutomatedFailover` to `AutomatedFailoverDuplex`:

```
snapmirror modify -destination-path <destination_path> -policy
AutomatedFailoverDuplex
```

2. Modifying the policy triggers a resync. Wait for the resync to complete and confirm the relationship is

Insync:

```
snapmirror show -destination-path <destination_path>
```

3. If the existing hosts are local to the primary cluster, add the host to the second cluster and establish connectivity with respective access to each cluster.
4. On the secondary site, add a new igroup and initiator for the new hosts and set the host proximity for host affinity to its local site. Map the LUNs to the igroup.

```
SiteB::> igroup create -vserver <svm_name> -igroup <igroup>
SiteB::> igroup add -vserver <svm_name> -igroup <igroup> -initiator
<host_name>
SiteB::> lun mapping create -igroup <igroup> -path <path_name>
```

5. Discover the paths on the hosts and verify the hosts have an Active/Optimized path to the storage LUN from the preferred cluster
6. Deploy the application and distribute the VM workloads across clusters.

Convert from symmetric active/active to an asymmetric iSCSI or FC relationship

If you’ve configured symmetric active/active protection using iSCSI or FC, you can convert the relationship to asymmetric protection using the ONTAP CLI.

Steps

1. Move all the VM workloads to the host local to the source cluster.
2. Remove the igroup configuration for the hosts not managing the VM instances then modify the igroup configuration to terminate igroup replication.

```
igroup modify -vserver <svm_name> -igroup <igroup> -replication-peer -
```

3. On the secondary site, unmap the LUNs.

```
SiteB::> lun mapping delete -vserver <svm_name> -igroup <igroup> -path <>
```

4. On the secondary site, delete the symmetric active/active relationship.

```
SiteB::> snapmirror delete -destination-path <destination_path>
```

5. On the primary site, release the symmetric active/active relationship.
```
SiteA::> snapmirror release -destination-path <destination_path> -relationship
-info-only true
```

6. From the secondary site, create a relationship to the same set of volumes with the `AutomatedFailover` policy to resynchronize the relationship.

```
SiteB::> snapmirror create -source-path <source_path> -destination-path
<destination_path> -cg-item-mappings <source:@destination> -policy
AutomatedFailover
SiteB::> snapmirror resync -destination-path vs1:/cg/cg1_dst -policy
```

```
<policy_type>
```

> The consistency group on the secondary site needs to be deleted before recreating the relationship. The destination volumes must be converted to type DP. To convert the volumes to DP, perform the `snapmirror resync` command with a non-`AutomatedFailover` policy: `MirrorAndVault`, `MirrorAllSnapshots`, or `Sync`.

7. Confirm the relationship Mirror State is `Snapmirrored` the Relationship Status is `Insync`.

```
snapmirror show -destination-path destination_path
```

8. Re-discover the paths from the host.

Manage SnapMirror active sync and protect data

Create a common snapshot between ONTAP consistency groups

In addition to the regularly scheduled snapshot operations, you can manually create a common snapshot between the volumes in the primary SnapMirror consistency group and the volumes in the secondary SnapMirror consistency group.

About this task

The scheduled snapshot creation interval is 12 hours.

Before you begin

- The SnapMirror group relationship must be in sync.

Steps

1. Create a common snapshot:

```
destination::>snapmirror update -destination-path vs1_dst:/cg/cg_dst
```

2. Monitor the progress of the update:

```
destination::>snapmirror show -fields newest-snapshot
```

Related information

- snapmirror show

Perform a planned failover of ONTAP clusters in a SnapMirror active sync relationship

In a planned failover of ONTAP clusters in a SnapMirror active sync relationship, you switch the roles of the primary and secondary clusters, so that the secondary cluster takes over from the primary cluster. During a failover, what is normally the secondary cluster processes input and output requests locally without disrupting client operations.

You may want to perform a planned failover to test the health of your disaster recovery configuration or to perform maintenance on the primary cluster.

About this task

A planned failover is initiated by the administrator of the secondary cluster. The operation requires switching the primary and secondary roles so that the secondary cluster takes over from the primary. The new primary cluster can then begin processing input and output requests locally without disrupting client operations.

Before you begin

- The SnapMirror active sync relationship must be in sync.
- You cannot initiate a planned failover when a nondisruptive operation is in process. Nondisruptive operations include volume moves, aggregate relocations, and storage failovers.
- The ONTAP Mediator must be configured, connected, and in quorum.

Steps

You can perform a planned failover using the ONTAP CLI or System Manager.

System Manager

> From ONTAP 9.14.1 through 9.8, SnapMirror active sync is referred to as SnapMirror Business Continuity (SM-BC).

1. In System Manager, select **Protection > Overview > Relationships**.
2. Identify the SnapMirror active sync relationship you want to failover. Next to its name, select the … next to the relationship's name, then select **Failover**.
3. To monitor the status of the failover, use the `snapmirror failover show` in the ONTAP CLI.

CLI

1. From the destination cluster, initiate the failover operation:

```
destination::>snapmirror failover start -destination-path
vs1_dst:/cg/cg_dst
```

2. Monitor the progress of the failover:

```
destination::>snapmirror failover show
```

3. When the failover operation is complete, you can monitor the SnapMirror synchronous protection relationship status from the destination:

```
destination::>snapmirror show
```

Related information

- snapmirror failover show
- snapmirror failover start

Recover from automatic unplanned ONTAP cluster failover operations

An automatic unplanned failover (AUFO) operation occurs when the primary cluster is down or isolated. The ONTAP Mediator detects when a failover occurs and, and executes an automatic unplanned failover to the the secondary cluster. The secondary cluster is converted to the primary and begins serving clients. This operation is performed only with assistance from the ONTAP Mediator.

> After the automatic unplanned failover, it is important to rescan the host LUN I/O paths so that there is no loss of I/O paths.

Reestablish the protection relationship after an unplanned failover

You can reestablish the protection relationship using System Manager or the ONTAP CLI.

System Manager

> **Steps**
> From ONTAP 9.14.1 through 9.8, SnapMirror active sync is referred to as SnapMirror Business Continuity (SM-BC).

1. Navigate to **Protection > Relationships** and wait for the relationship state to show "InSync."
2. To resume operations on the original source cluster, click ⋮ and select **Failover**.

CLI

You can monitor the status of the automatic unplanned failover using the `snapmirror failover show` command.

For example:

```
ClusterB::> snapmirror failover show -instance
Start Time: 9/23/2020 22:03:29
         Source Path: vs1:/cg/scg3
    Destination Path: vs3:/cg/dcg3
     Failover Status: completed
        Error Reason:
            End Time: 9/23/2020 22:03:30
Primary Data Cluster: cluster-2
Last Progress Update: -
       Failover Type: unplanned
  Error Reason codes: -
```

Refer to the EMS reference to learn about event messages and about corrective actions.

Resume protection in a fan-out configuration after failover

Beginning with ONTAP 9.15.1, SnapMirror active sync supports automatic reconfiguration in the fan-out leg after a failover event. The async fan-out leg can be a consistency group relationship or an independent volume relationship. For more information, see fan-out configurations.

If you're using ONTAP 9.14.1 or earlier and you experience a failover on the secondary cluster in the SnapMirror active sync relationship, the SnapMirror asynchronous destination becomes unhealthy. You must manually restore protection by deleting and recreating the relationship with the SnapMirror asynchronous endpoint.

Steps

1. Verify the failover has completed successfully:
   `snapmirror failover show`
2. On the SnapMirror asynchronous endpoint, delete the fan-out endpoint:
   `snapmirror delete -destination-path destination_path`
3. On the third site, create a SnapMirror asynchronous relationships between the new SnapMirror active sync primary volume and the async fan-out destination volume:

```
snapmirror create -source-path source_path -destination-path destination_path
-policy MirrorAllSnapshots -schedule schedule
```

4. Resynchronize the relationship:
   `snapmirror resync -destination-path destination_path`
5. Verify the relationship status and heath:
   `snapmirror show`

Related information

- snapmirror create
- snapmirror delete
- snapmirror failover show
- snapmirror resync

Monitor ONTAP SnapMirror active sync operations

You can monitor the following SnapMirror active sync operations to ensure the health of your SnapMirror active sync configuration:

- ONTAP Mediator
- Planned failover operations
- Automatic unplanned failover operations
- SnapMirror active sync availability

> Beginning with ONTAP 9.15.1, System Manager displays the status of your SnapMirror active sync relationship from either cluster. You can also monitor the ONTAP Mediator's status from either cluster in System Manager.

ONTAP Mediator

During normal operations, the ONTAP Mediator state should be connected. If it's in any other state, this might indicate an error condition. You can review the Event Management System (EMS) messages to determine the error and appropriate corrective actions.

Planned failover operations

You can monitor status and progress of a planned failover operation using the `snapmirror failover show` command. For example:

```
ClusterB::> snapmirror failover start -destination-path vs1:/cg/dcg1
```

Once the failover operation is complete, you can monitor the SnapMirror protection status from the new destination cluster. For example:

```
ClusterA::> snapmirror show
```

Refer to the EMS reference to learn about event messages and corrective actions.

Automatic unplanned failover operations

During an unplanned automatic failover, you can monitor the status of the operation using the `snapmirror failover show` command.

```
ClusterB::> snapmirror failover show -instance
Start Time: 9/23/2020 22:03:29
         Source Path: vs1:/cg/scg3
     Destination Path: vs3:/cg/dcg3
      Failover Status: completed
         Error Reason:
             End Time: 9/23/2020 22:03:30
Primary Data Cluster: cluster-2
Last Progress Update: -
       Failover Type: unplanned
  Error Reason codes: -
```

Refer to the EMS reference to learn about event messages and about corrective actions.

SnapMirror active sync availability

You can check the availability of the SnapMirror active sync relationship using a series of commands, either on the primary cluster, the secondary cluster, or both.

Commands you use include the `snapmirror mediator show` command on both the primary and secondary cluster to check the connection and quorum status, the `snapmirror show` command, and the `volume show` command. For example:

```
SMBC_A::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
10.236.172.86    SMBC_B           connected         true

SMBC_B::*> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
10.236.172.86    SMBC_A           connected         true

SMBC_B::*> snapmirror show -expand

Progress
Source            Destination Mirror  Relationship   Total
Last
Path        Type  Path        State   Status         Progress  Healthy
Updated
----------- ---- ------------ ------- -------------- --------- -------
--------
vs0:/cg/cg1 XDP  vs1:/cg/cg1_dp Snapmirrored Insync -         true    -
vs0:vol1    XDP  vs1:vol1_dp  Snapmirrored Insync   -         true    -
2 entries were displayed.

SMBC_A::*> volume show -fields is-smbc-master,smbc-consensus,is-smbc-
failover-capable -volume vol1
vserver volume is-smbc-master is-smbc-failover-capable smbc-consensus
------- ------ -------------- ------------------------ --------------
vs0     vol1   true           false                    Consensus

SMBC_B::*> volume show -fields is-smbc-master,smbc-consensus,is-smbc-
failover-capable -volume vol1_dp
vserver volume  is-smbc-master is-smbc-failover-capable smbc-consensus
------- ------- -------------- ------------------------ --------------
vs1     vol1_dp false          true                     No-consensus
```

Add or remove volumes to an ONTAP consistency group

As your application workload requirements change, you may need to add or remove volumes from a consistency group to ensure business continuity. The process of adding and removing volumes in an an active SnapMirror active sync relationship depends on the version of ONTAP you are using.

In most instances, this is a disruptive process requiring you to delete the SnapMirror relationship, modify the consistency group, then resume protection. Beginning with ONTAP 9.13.1, adding volumes to a consistency group with an active SnapMirror relationship is a non-disruptive operation.

About this task

- In ONTAP 9.9.1, you can add or remove volumes to a consistency group using the ONTAP CLI.
- Beginning with ONTAP 9.10.1, it is recommended that you manage consistency groups through System Manager or with the ONTAP REST API.

  If you want to change the composition of the consistency group by adding or removing a volume, you must first delete the original relationship and then create the consistency group again with the new composition.

- Beginning with ONTAP 9.13.1, you can non-disruptively add volumes to a consistency group with an active SnapMirror relationship from the source or destination. This action is not supported with the NVMe protocol.

  Removing volumes is a disruptive operation. You must delete the SnapMirror relationship before removing volumes.

ONTAP 9.9.1-9.13.0

Before you begin

- You cannot begin to modify the consistency group while it is in the `InSync` state.
- The destination volume should be of type DP.
- The new volume you add to expand the consistency group must have a pair of common snapshots between the source and destination volumes.

Steps

The examples shown in two volume mappings: `vol_src1` ←→ `vol_dst1` and `vol_src2` ←→ `vol_dst2`, in a consistency group relationship between the end points `vs1_src:/cg/cg_src` and `vs1_dst:/cg/cg_dst`.

1. On the source and destination clusters, verify there is a common snapshot between the source and destination clusters with the command `snapshot show -vserver svm_name -volume volume_name -snapshot snapmirror`

   ```
   source::>snapshot show -vserver vs1_src -volume vol_src3 -snapshot
   snapmirror*
   ```

   ```
   destination::>snapshot show -vserver vs1_dst -volume vol_dst3 -snapshot
   snapmirror*
   ```

2. If no common snapshot exists, create and initialize a FlexVol SnapMirror relationship:

   ```
   destination::>snapmirror initialize -source-path vs1_src:vol_src3
   -destination-path vs1_dst:vol_dst3
   ```

3. Delete the consistency group relationship:

   ```
   destination::>snapmirror delete -destination-path vs1_dst:/cg/cg_dst
   ```

4. Release the source SnapMirror relationship and retain the common snapshots:

   ```
   source::>snapmirror release -relationship-info-only true -destination-path
   vs1_dst:vol_dst3
   ```

5. Unmap the LUNs and delete the existing consistency group relationship:

   ```
   destination::>lun mapping delete -vserver vs1_dst -path <lun_path> -igroup
   <igroup_name>
   ```

   > The destination LUNs are unmapped, while the LUNs on the primary copy continue to serve the host I/O.

   ```
   destination::>snapmirror delete -destination-path vs1_dst:/cg/cg_dst
   ```

   ```
   source::>snapmirror release -destination-path vs1_dst:/cg/cg_dst
   -relationship-info-only true
   ```

6. **If you are using ONTAP 9.10.1 through 9.13.0,** delete and recreate and the consistency group on

the source with the correct composition. Follow the steps in Delete a consistency group and then Configure a single consistency group. In ONTAP 9.10.1 and later, you must perform the delete and create operations in System Manager or with the ONTAP REST API; there is no CLI procedure.

If you are using ONTAP 9.9.1, skip to the next step.

7. Create the new consistency group on the destination with the new composition:

```
destination::>snapmirror create -source-path vs1_src:/cg/cg_src
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings vol_src1:@vol_dst1,
vol_src2:@vol_dst2, vol_src3:@vol_dst3
```

8. Resynchronize the zero RTO consistency group relationship to ensure it is in sync:

```
destination::>snapmirror resync -destination-path vs1_dst:/cg/cg_dst
```

9. Remap the LUNs that you unmapped in Step 5:

```
destination::> lun map -vserver vs1_dst -path lun_path -igroup igroup_name
```

10. Rescan host LUN I/O paths to restore all paths to the LUNs.

ONTAP 9.13.1 and later

Beginning with ONTAP 9.13.1, you can non-disruptively add volumes to a consistency group with an active SnapMirror active sync relationship. SnapMirror active sync supports adding volumes from both the source or destination.

From ONTAP 9.14.1 through 9.8, SnapMirror active sync is referred to as SnapMirror Business Continuity (SM-BC).

For details on adding volumes from the source consistency group, see Modify a consistency group.

Add a volume from the destination cluster

1. On the destination cluster, select **Protection** > **Relationships**.
2. Find the SnapMirror configuration you want to add volumes to. Select ⋮ then **Expand**.
3. Select the volume relationships whose volumes are to be added to consistency group
4. Select **Expand**.

- snapmirror delete
- snapmirror initialize
- snapmirror release
- snapmirror resync

Upgrade and revert with ONTAP SnapMirror active sync

SnapMirror active sync is supported beginning with ONTAP 9.9.1. Upgrading and reverting your ONTAP cluster or controllers has implications on your SnapMirror active sync relationships depending on the ONTAP version to which you are upgrading or reverting.

Refresh a cluster

Beginning with ONTAP 9.16.1, SnapMirror active sync supports four-node clusters in symmetric active/active configurations. You can use the four-node cluster to upgrade controllers and storage.

Before you begin

- Review the requirements for four-node clusters.
- You can create asymmetrical configurations during the tech refresh process; however, you should return to a symmetrical configuration after completing the refresh.
- These instructions apply to an existing four-node configuration with 50 or fewer consistency groups and 400 or fewer volume endpoints.

Steps

1. Move all the SnapMirror active sync volumes onto a *single* high-availability (HA) pair.
2. Remove the unused nodes from the cluster.
3. Add the new nodes to the cluster.
4. Move all the volumes into the new nodes.
5. Remove the unused nodes from the cluster then replace them with the new nodes.

Upgrade ONTAP with SnapMirror active sync

To use SnapMirror active sync, all nodes on the source and destination clusters must be running ONTAP 9.9.1 or later.

When upgrading ONTAP with active SnapMirror active sync relationships, you should use automated nondisruptive upgrade (ANDU). Using ANDU ensures your SnapMirror active sync relationships are in sync and healthy during the upgrade process.

There are no configuration steps to prepare SnapMirror active sync deployments for ONTAP upgrades. However, it is recommended that before and after the upgrade, you should check that:

- SnapMirror active sync relationships are in sync.
- There are no errors related to SnapMirror in the event log.
- The Mediator is online and healthy from both clusters.
- All hosts can see all paths properly to protect LUNs.

> When you upgrade clusters from ONTAP 9.9.1 or 9.9.1 to ONTAP 9.10.1 and later, ONTAP creates new consistency groups on both source and destination clusters for SnapMirror active sync relationships that can be configured using System Manager.

> The `snapmirror quiesce` and `snampirror resume` commands are not supported with SnapMirror active sync.

Revert to ONTAP 9.9.1 from ONTAP 9.10.1

To revert relationships from 9.10.1 to 9.9.1, SnapMirror active sync relationships must be deleted, followed by the 9.10.1 consistency group instance. Consistency groups with an active SnapMirror active sync relationship cannot be deleted. Any FlexVol volumes that were upgraded to 9.10.1 previously associated with another Smart Container or Enterprise App in 9.9.1 or earlier will no longer be associated on revert. Deleting consistency groups does not delete the constituent volumes or volume granular snapshots. Refer to Delete a consistency group for more information on this task in ONTAP 9.10.1 and later.

Revert from ONTAP 9.9.1

> ⓘ SnapMirror active sync is not supported with mixed ONTAP clusters than include releases earlier than ONTAP 9.9.1.

When you revert from ONTAP 9.9.1 to an earlier release of ONTAP, you must be aware of the following:

- If the cluster hosts an SnapMirror active sync destination, reverting to ONTAP 9.8 or earlier is not allowed until the relationship is broken and deleted.
- If the cluster hosts an SnapMirror active sync source, reverting to ONTAP 9.8 or earlier is not allowed until the relationship is released.
- All user-created custom SnapMirror active sync policies must be deleted before reverting to ONTAP 9.8 or earlier.

To meet these requirements, see Remove a SnapMirror active sync configuration.

Steps

1. Confirm your readiness to revert, entering the following command from one of the clusters in the SnapMirror active sync relationship:

   `cluster::> system node revert-to -version 9.7 -check-only`

   The following sample output shows a cluster that is not ready to revert with instructions for clean up.

```
cluster::> system node revert-to -version 9.7 -check-only
Error: command failed: The revert check phase failed. The following
issues must be resolved before revert can be completed. Bring the data
LIFs down on running vservers. Command to list the running vservers:
vserver show -admin-state running Command to list the data LIFs that are
up: network interface show -role data -status-admin up Command to bring
all data LIFs down: network interface modify {-role data} -status-admin
down
Disable snapshot policies.
    Command to list snapshot policies: "snapshot policy show".
    Command to disable snapshot policies: "snapshot policy modify
-vserver
   * -enabled false"

   Break off the initialized online data-protection (DP) volumes and
delete
   Uninitialized online data-protection (DP) volumes present on the
local
   node.
    Command to list all online data-protection volumes on the local
```

```
node:
   volume show -type DP -state online -node <local-node-name>
    Before breaking off the initialized online data-protection volumes,
   quiesce and abort transfers on associated SnapMirror relationships
and
   wait for the Relationship Status to be Quiesced.
    Command to quiesce a SnapMirror relationship: snapmirror quiesce
    Command to abort transfers on a SnapMirror relationship: snapmirror
   abort
    Command to see if the Relationship Status of a SnapMirror
relationship
   is Quiesced: snapmirror show
    Command to break off a data-protection volume: snapmirror break
    Command to break off a data-protection volume which is the
destination
   of a SnapMirror relationship with a policy of type "vault":
snapmirror
   break -delete-snapshots
    Uninitialized data-protection volumes are reported by the
"snapmirror
   break" command when applied on a DP volume.
    Command to delete volume: volume delete

   Delete current version snapshots in advanced privilege level.
    Command to list snapshots: "snapshot show -fs-version 9.9.1"
    Command to delete snapshots: "snapshot prepare-for-revert -node
   <nodename>"

   Delete all user-created policies of the type active-strict-sync-
mirror
   and active-sync-mirror.
   The command to see all active-strict-sync-mirror and active-sync-
mirror
   type policies is:
    snapmirror policy show -type
   active-strict-sync-mirror,active-sync-mirror
   The command to delete a policy is :
    snapmirror policy delete -vserver <SVM-name> -policy <policy-name>
```

2. Once you've satisfied the requirements of the revert check, see Revert ONTAP.

Remove an ONTAP SnapMirror active sync configuration

If you no longer require zero RTO SnapMirror synchronous protection, you can delete your SnapMirror active sync relationship.

Remove an asymmetric configuration

- Before you delete the SnapMirror active sync relationship, all LUNs in the destination cluster must be unmapped.
- After the LUNs are unmapped and the host is rescanned, the SCSI target notifies the hosts that the LUN inventory has changed. The existing LUNs on the zero RTO secondary volumes change to reflect a new identity after the zero RTO relationship is deleted. Hosts discover the secondary volume LUNs as new LUNs that have no relationship to the source volume LUNs.
- The secondary volumes remain DP volumes after the relationship is deleted. You can issue the `snapmirror break` command to convert them to read/write.
- Deleting the relationship is not allowed in the failed-over state when the relationship is not reversed.

Steps

1. From the secondary cluster, remove the SnapMirror active sync consistency group relationship between the source endpoint and destination endpoint:

   ```
   destination::>snapmirror delete -destination-path vs1_dst:/cg/cg_dst
   ```

2. From the primary cluster, release the consistency group relationship and the snapshots created for the relationship:

   ```
   source::>snapmirror release -destination-path vs1_dst:/cg/cg_dst
   ```

3. Perform a host rescan to update the LUN inventory.
4. Beginning with ONTAP 9.10.1, deleting the SnapMirror relationship does not delete the consistency group. If you want to delete the consistency group, you must use System Manager or the ONTAP REST API. See Delete a consistency group for more information.

Remove iSCSI or FC symmetric active/active configuration

You can remove a symmetric configuration using System Manager or the ONTAP CLI. In both interfaces, there are different steps for uniform and non-uniform configurations.

System Manager

Steps for a uniform configuration

1. On the primary site, remove the remote hosts from the igroup and terminate replication.
   a. Navigate to **Hosts** > **SAN Initiator Groups**.
   b. Select the igroup you want to modify then **Edit**.
   c. Remove the remote initiator and terminate igroup replication. Select **Save**.
2. On the secondary site, delete the replicated relationship by unmapping the LUNs.
   a. Navigate to **Hosts** > **SAN Initiator Groups**.
   b. Select the igroup with the SnapMirror relationship, then **Delete**.
   c. In the dialog box, select the **Unmap the associated LUNs** box then **Delete**.
   d. Navigate to **Protection** > **Relationships**.
   e. Select the SnapMirror active sync relationship then **Release** to delete the relationships.

Steps for a non-uniform configuration

1. On the primary site, remove the remote hosts from the igroup and terminate replication.
   a. Navigate to **Hosts** > **SAN Initiator Groups**.
   b. Select the igroup you want to modify then **Edit**.
   c. Remove the remote initiator and terminate igroup replication. Select **Save**.
2. On the secondary site, remove the SnapMirror active sync relationship.
   a. Navigate to **Protection** > **Relationships**.
   b. Select the SnapMirror active sync relationship then **Release** to delete the relationships.

CLI

Steps for a uniform configuration

1. Move all the VM workloads to the host local to source cluster of SnapMirror active sync.
2. On the source cluster, remove the initiators from the igroup and modify the igroup configuration to terminate igroup replication.

```
SiteA::> igroup remove -vserver <svm_name> -igroup <igroup_name> -os-type
<os_type> -initiator <host2>
SiteA::> igroup modify -vserver <svm_name> -igroup <igroup_name> -os-type
<os_type> -replication-peer "-"
```

3. On the secondary site, delete the LUN mapping and remove the igroup configuration:

```
SiteB::> lun mapping delete -vserver <svm_name> -igroup <igroup_name> -path
<>
SiteB::> igroup delete -vserver <svm_name> -igroup <igroup_name>
```

4. On the secondary site, delete the SnapMirror active sync relationship.

```
SiteB::> snapmirror delete -destination-path destination_path
```

5. On the primary site, release the SnapMirror active sync relationship from primary site.

```
SiteA::> snapmirror release -destination-path <destination_path>
```

6. Rediscover the paths to verify that only the local path is available to the host.

Steps for a non-uniform configuration

1. Move all the VM workloads to the host local to source cluster of SnapMirror active sync.
2. On the source cluster, remove the initiators from the igroup.

```
SiteA::> igroup remove -vserver <svm_name> -igroup <igroup_name> -initiator
<host2>
```

3. On the secondary site, delete the LUN mapping and remove the igroup configuration:

```
SiteB::> lun mapping delete -vserver <svm_name> -igroup <igroup_name> -path
<>
SiteB::> igroup delete -vserver <svm_name> -igroup <igroup_name>
```

4. On the secondary site, delete the SnapMirror active sync relationship.

```
SiteB::> snapmirror delete -destination-path <destination_path>
```

5. On the primary site, release the SnapMirror active sync relationship from primary site.

```
SiteA::> snapmirror release -destination-path <destination_path>
```

6. Rediscover the paths to verify that only the local path is available to the host.

Remove an NVMe symmetric active/active configuration

System Manager

Steps

1. On the source cluster, navigate to **Protection > Replication**.
2. Locate the relationship you want to remove, select ⋮ and choose **Delete**.

CLI

1. From the destination cluster, delete the SnapMirror active sync relationship.

   `snapmirror delete -destination-path <destination_path> -unmap-namespace true`

   Example:

   ```
   DST::> snapmirror delete -destination-path vs1:/cg/cg_dst_1 -force
   true
   ```

   The subsystem and its namespaces are removed from the secondary cluster.

2. From the source cluster, release the SnapMirror active sync relationship from primary site.

   `snapmirror release -destination-path <destination_path>`

   Example:

   ```
   SRC::> snapmirror release -destination-path vs1:/cg/cg_dst_1
   ```

3. Rediscover the paths to verify that only the local path is available to the host.

Remove ONTAP Mediator or ONTAP Cloud Mediator

If you want to remove an existing ONTAP Mediator or ONTAP Cloud Mediator configuration from your ONTAP clusters, you can do so by using the `snapmirror mediator remove` command. For example, you can use only one type of Mediator at a time, so you must remove one instance before you install the other.

Steps

You can remove ONTAP Mediator or ONTAP Cloud Mediator by completing one of the following steps.

ONTAP Mediator

1. Remove ONTAP Mediator:

   `snapmirror mediator remove -mediator-address <address> -peer-cluster <peerClusterName>`

   Example:

   ```
   snapmirror mediator remove -mediator-address 12.345.678.90 -peer
   -cluster cluster_xyz
   ```

ONTAP Cloud Mediator

1. Remove ONTAP Cloud Mediator:

   `snapmirror mediator remove -peer-cluster <peerClusterName> -type cloud`

   Example:

   ```
   snapmirror mediator remove -peer-cluster cluster_xyz -type cloud
   ```

Related information

- snapmirror mediator remove

Troubleshoot

ONTAP SnapMirror delete operation fails in takover state

Use the following information if the `snapmirror delete` command fails when a SnapMirror active sync consistency group relationship is in takeover state.

Issue:

When ONTAP 9.9.1 is installed on a cluster, executing the `snapmirror delete` command fails when a SnapMirror active sync consistency group relationship is in takeover state.

Example:

```
C2_cluster::> snapmirror delete  vs1:/cg/dd

Error: command failed: RPC: Couldn't make connection
```

Solution

When the nodes in a SnapMirror active sync relationship are in takeover state, perform the SnapMirror delete and release operation with the "-force" option set to true.

Example:

```
C2_cluster::> snapmirror delete  vs1:/cg/dd -force true

Warning: The relationship between source "vs0:/cg/ss" and destination
         "vs1:/cg/dd" will be deleted, however the items of the
destination
         Consistency Group might not be made writable, deletable, or
modifiable
         after the operation. Manual recovery might be required.
Do you want to continue? {y|n}: y
Operation succeeded: snapmirror delete for the relationship with
destination "vs1:/cg/dd".
```

Related information

- snapmirror delete

Failure creating an ONTAP SnapMirror relationship and initializing consistency group

Use the following information if the creation of a SnapMirror relationship and consistency group initialization fails.

Issue:

Creation of SnapMirror relationship and consistency group initialization fails.

Solution:

Ensure that you have not exceeded the limit of consistency groups per cluster. Consistency group limits in SnapMirror active sync are platform independent and differ based on the version of ONTAP. See Object limits for guidance specific to your ONTAP version.

Error:

If the consistency group is stuck initializing, check the status of your consistency group initializations with the ONTAP REST API, System Manager or the command `sn show -expand`.

> From ONTAP 9.14.1 through 9.8, SnapMirror active sync is referred to as SnapMirror Business Continuity (SM-BC).

Solution:

If consistency groups fail to initialize, remove the SnapMirror active sync relationship, delete the consistency group, then recreate the relationship and initialize it. This workflow differs depending on the version of ONTAP you are using.

If you are using ONTAP 9.9.1	If you are using ONTAP 9.10.1 or later

1. Remove the SnapMirror active sync configuration 2. Create a consistency group relationship then Initialize the consistency group relationship	1. Under **Protection > Relationships**, find the SnapMirror active sync relationship on the consistency group. Select ⋮, then **Delete** to remove the SnapMirror active sync relationship. 2. Delete the consistency group 3. Configure the consistency group

Planned ONTAP cluster failover unsuccessful

Use the following information if the planned failover operation is unsuccessful.

Issue:

After executing the `snapmirror failover start` command, the output for the `snapmirror failover show` command displays a message indicates that a nondisruptive operation is in progress.

Example:

```
Cluster1::> snapmirror failover show
Source Destination Error
Path Path Type Status start-time end-time Reason
-------- ----------- -------- --------- ---------- ---------- ----------
vs1:/cg/cg vs0:/cg/cg planned failed 10/1/2020 10/1/2020 SnapMirror
Failover cannot start because a volume move is running. Retry the command
once volume move has finished.
                                                          08:35:04
08:35:04
```

Cause:

A planned failover cannot begin when a nondisruptive operation is in progress, including volume move, aggregate relocation, and storage failover.

Solution:

Wait for the nondisruptive operation to complete and try the failover operation again.

Related information

- snapmirror failover show
- snapmirror failover start

ONTAP Mediator or ONTAP Cloud Mediator not reachable or Mediator quorum status is false

Use the following information if the ONTAP Mediator or ONTAP Cloud Mediator is not reachable or the Mediator quorum status is false.

Issue:

After executing the `snapmirror failover start` command, the output for the `snapmirror failover show` command displays a message indicating that either the ONTAP Mediator or ONTAP Cloud Mediator is not configured.

See Configure the ONTAP Mediator and clusters for SnapMirror active sync or Configure the ONTAP Cloud Mediator for SnapMirror active sync.

Example:

```
Cluster1::> snapmirror failover show
Source Destination Error
Path Path Type Status start-time end-time Reason
-------- ----------- -------- --------- ---------- ---------- ----------
vs0:/cg/cg vs1:/cg/cg planned failed 10/1/2020 10/1/2020 SnapMirror
failover cannot start because the source-side precheck failed. reason:
Mediator not configured.
05:50:42 05:50:43
```

Cause:

Mediator is not configured or there are network connectivity issues.

Solution:

If the ONTAP Mediator is not configured, you must configure the ONTAP Mediator before you can establish a SnapMirror active sync relationship. Fix any network connectivity issues. Make sure Mediator is connected and quorum status is true on both the source and destination site using the snapmirror mediator show command. For more information, see Configure the ONTAP Mediator.

Example:

```
cluster::> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
10.234.10.143    cluster2         connected         true
```

Related information

- snapmirror failover show
- snapmirror failover start
- snapmirror mediator show

ONTAP Cloud Mediator is reachable but responding slowly

Use the following information if the ONTAP Cloud Meditor fails with an error that says the ping latency is higher than the recommended latency.

Issue:

System Manager:
The Cloud Mediator service is reachable but it's responding slowly.

CLI:
The `mediator add` command fails with the error:
`Error: command failed: The ping latency of the BlueXP cloud server is <x> ms which is higher than twice the recommended latency of 200 ms.`

Cause:
The clusters might not be located in proximity to the BlueXP cloud or there are network path bottlenecks.

Solution:

- Check the geographical location and proximity to the BlueXP cloud (US East).
- Optimize network path or address bottlenecks.
- Measure round trip time (RTT) using network tools, and reduce latency to within recommended limits.
- Use an HTTP proxy to improve performance.

See Configure the ONTAP Cloud Mediator and clusters for SnapMirror active sync.

Automatic unplanned failover not triggered on Site B

Use the following information if a failure on Site A does not trigger an unplanned failover on Site B.

Issue:
A failure on Site A does not trigger an unplanned failover on Site B.

Possible cause #1:
The ONTAP Mediator or the ONTAP Cloud Mediator is not configured. To determine if this is the cause, issue the `snapmirror mediator show` command on the Site B cluster.

Example:

```
Cluster2::> snapmirror mediator show
This table is currently empty.
```

This example indicates that the Mediator is not configured on Site B.

Solution:
Ensure that Mediator is configured on both clusters, that the status is connected, and quorum is set to True.

Possible cause #2:
SnapMirror consistency group is out of sync. To determine if this is the cause, view the event log to view if the consistency group was in sync during the time at which the Site A failure occurred.

Example:

```
cluster::> event log show -event *out.of.sync*

Time                Node             Severity      Event
------------------- ---------------- -------------
---------------------------
10/1/2020 23:26:12  sti42-vsim-ucs511w ERROR       sms.status.out.of.sync:
Source volume "vs0:zrto_cg_556844_511u_RW1" and destination volume
"vs1:zrto_cg_556881_511w_DP1" with relationship UUID "55ab7942-03e5-11eb-
ba5a-005056a7dc14" is in "out-of-sync" status due to the following reason:
"Transfer failed."
```

Solution:

Complete the following steps to perform a forced failover on Site B.

1. Unmap all LUNs belonging to the consistency group from Site B.
2. Delete the SnapMirror consistency group relationship using the `force` option.
3. Enter the `snapmirror break` command on the consistency group constituent volumes to convert volumes from DP to R/W, to enable I/O from Site B.
4. Boot up the Site A nodes to create a zero RTO relationship from Site B to Site A.
5. Release the consistency group with `relationship-info-only` on Site A to retain common snapshot and unmap the LUNs belonging to the consistency group.
6. Convert volumes on Site A from R/W to DP by setting up a volume level relationship using either the Sync policy or Async policy.
7. Issue the `snapmirror resync` to synchronize the relationships.
8. Delete the SnapMirror relationships with the Sync policy on Site A.
9. Release the SnapMirror relationships with Sync policy using `relationship-info-only true` on Site B.
10. Create a consistency group relationship from Site B to Site A.
11. Perform a consistency group resync from Site A, and then verify that the consistency group is in sync.
12. Rescan host LUN I/O paths to restore all paths to the LUNs.

- snapmirror mediator show
- snapmirror resync

Link between Site B and ONTAP Mediator down and Site A down

To check on the connection of the ONTAP Mediator or the ONTAP Cloud Mediator, use the `snapmirror mediator show` command. If the connection status is unreachable and Site B is unable to reach Site A, you will have an output similar to the one below. Follow the steps in the solution to restore connection

Example:

Using ONTAP Cloud Mediator output `snapmirror mediator show`command:

```
cluster::> snapmirror mediator show
Mediator Address Peer Cluster    Connection Status Quorum Status Type
---------------- ---------------- ----------------- ------------- -------
0.0.0.0          C1_cluster       unreachable       true          cloud
```

Using ONTAP Mediator output `snapmirror mediator show`command:

```
cluster::> snapmirror mediator show
Mediator Address Peer Cluster     Connection Status Quorum Status
---------------- ---------------- ----------------- -------------
10.237.86.17     C1_cluster       unreachable       true
SnapMirror consistency group relationship status is out of sync.

C2_cluster::> snapmirror show -expand
Source            Destination Mirror  Relationship   Total
Last
Path        Type  Path        State   Status         Progress  Healthy
Updated
----------- ---- ------------ ------- -------------- --------- -------
--------
vs0:/cg/src_cg_1 XDP vs1:/cg/dst_cg_1 Snapmirrored OutOfSync - false   -
vs0:zrto_cg_655724_188a_RW1 XDP vs1:zrto_cg_655755_188c_DP1 Snapmirrored
OutOfSync - false -
vs0:zrto_cg_655733_188a_RW2 XDP vs1:zrto_cg_655762_188c_DP2 Snapmirrored
OutOfSync - false -
vs0:zrto_cg_655739_188b_RW1 XDP vs1:zrto_cg_655768_188d_DP1 Snapmirrored
OutOfSync - false -
vs0:zrto_cg_655748_188b_RW2 XDP vs1:zrto_cg_655776_188d_DP2 Snapmirrored
OutOfSync - false -
5 entries were displayed.

Site B cluster is unable to reach Site A.
C2_cluster::> cluster peer show
Peer Cluster Name         Cluster Serial Number Availability
Authentication
------------------------- --------------------- --------------
--------------
C1_cluster            1-80-000011           Unavailable    ok
```

Solution

Force a failover to enable I/O from Site B and then establish a zero RTO relationship from Site B to Site A. Complete the following steps to perform a forced failover on Site B.

1. Unmap all LUNs belonging to the consistency group from Site B.
2. Delete the SnapMirror consistency group relationship using the force option.
3. Enter the SnapMirror break command (`snapmirror break -destination_path svm:_volume_`) on the consistency group constituent volumes to convert volumes from DP to RW, to enable I/O from Site B.

   You must issue the SnapMirror break command for each relationship in the consistency group. For example, if there are three volumes in the consistency group, you will issue the command for each volume.

4. Boot up the Site A nodes to create a zero RTO relationship from Site B to Site A.
5. Release the consistency group with relationship-info-only on Site A to retain common snapshot and unmap the LUNs belonging to the consistency group.
6. Convert volumes on Site A from RW to DP by setting up a volume level relationship using either Sync policy or Async policy.
7. Issue the `snapmirror resync` command to synchronize the relationships.
8. Delete the SnapMirror relationships with Sync policy on Site A.
9. Release the SnapMirror relationships with Sync policy using relationship-info-only true on Site B.
10. Create a consistency group relationship between Site B to Site A.
11. From the source cluster, resynchronize the consistency group. Verify the consistency group state is in sync.
12. Rescan the host LUN I/O paths to restore all paths to the LUNs.

Link between Site A and ONTAP Mediator down and Site B down

When using SnapMirror active sync, you may lose connectivity between the ONTAP Mediator or your peered clusters. You can diagnose the issue by checking the connection, availability, and consensus status of the different parts of the SnapMirror active sync relationship then forcefully resuming connection.

Table 4. Determining the cause

What to check	CLI command	Indicator
Mediator from Site A	`snapmirror mediator show`	The connection status displays as `unreachable`
Site B connectivity	`cluster peer show`	Availability displays as `unavailable`
Consensus status of the SnapMirror active sync volume	`volume show volume_name -fields smbc-consensus`	The `sm-bc consensus` field displays `Awaiting-consensus`

For additional information about diagnosing and resolving this issue, refer to the Knowledge Base article Link between Site A and Mediator down and Site B down when using SnapMirror active sync.

ONTAP SnapMirror delete operation fails when fence is set on destination volume

Use the following information if the SnapMirror delete operation fails when any of the destination volumes have redirection fence set.

Issue:

SnapMirror delete operation fails when any of the destination volumes have redirection fence set.

Solution

Performing the following operations to retry the redirection and remove the fence from the destination volume.

- SnapMirror resync
- SnapMirror update

Volume move operation stuck when ONTAP primary is down

Use the following information if a volume move operation is stuck indefinitely in cutover deferred state when the primary site is down in a SnapMirror active sync relationship.

Issue:

A volume move operation is stuck indefinitely in cutover deferred state when the primary site is down in a SnapMirror active sync relationship.
When the primary site is down, the secondary site performs an automatic unplanned failover (AUFO). When a volume move operation is in progress when the AUFO is triggered the volume move becomes stuck.

Solution:

Abort the volume move instance that is stuck and restart the volume move operation.

ONTAP SnapMirror release fails when unable to delete snapshot

Use the following information if the SnapMirror release operation fails when the snapshot cannot be deleted.

Issue:

The SnapMirror release operation fails when the snapshot cannot be deleted.

Solution:

The snapshot contains a transient tag. Use the `snapshot delete` command with the `-ignore-owners` option to remove the transient snapshot.

```
snapshot delete -volume <volume_name> -snapshot <snapshot_name> -ignore-owners
true -force true
```

Retry the `snapmirror release` command.

Related information

- snapmirror release

Volume move reference snapshot shows as the newest for ONTAP SnapMirror relationship

Use the following information if the volume move reference snapshot shows as the newest for the SnapMirror relationship after a volume move operation.

Issue:

After performing a volume move operation on a consistency group volume, the volume move reference snapshot might incorrectly display as the newest for the SnapMirror relationship.

You can view the newest snapshot with the following command:

```
snapmirror show -fields newest-snapshot status -expand
```

Solution:

Manually perform a `snapmirror resync` or wait for the next automatic resync operation after the volume move operation completes.

ONTAP Mediator for MetroCluster and SnapMirror active sync

Learn about ONTAP Mediator

This documentation refers to the on-premise version of ONTAP Mediator. For information about ONTAP Cloud Mediator, available beginning with ONTAP 9.17.1, see the SnapMirror active sync documentation.

ONTAP Mediator provides several functions for ONTAP features:

- Provides a persistent and fenced store for HA metadata.
- Serves as a ping proxy for controller liveliness.
- Provides synchronous node health query functionality to aid in quorum determination.

ONTAP Mediator provides two additional systemctl services:

- **`ontap_mediator.service`**

  Maintains the REST API server for managing the ONTAP relationships.

- **`mediator-scst.service`**

  Controls the startup and shutdown of the iSCSI module (SCST).

Tools provided for the system administrator

Tools provided for the system administrator:

* **`/usr/local/bin/mediator_change_password`**

  Sets a new API password when the current API username and password are provided.

* **`/usr/local/bin/mediator_change_user`**

  Sets a new API username when the current API username and password are provided.

* **`/usr/local/bin/mediator_generate_support_bundle`**

  Generates a local tgz file containing all useful support information needed for communication with NetApp customer support. This includes application configuration, logs, and some system information. The bundles are generated on the local disk and can be transferred manually, as needed. Storage location: /opt/netapp/data/support_bundles/

* **`/usr/local/bin/uninstall_ontap_mediator`**

  Removes the ONTAP Mediator package and the SCST kernel module. This includes all configuration, logs, and mailbox data.

* **`/usr/local/bin/mediator_unlock_user`**

  Releases a lock-out on the API user account if the authentication retry limit was reached. This feature is used to prevent brute force password derivation. It prompts the user for the correct username and password.

* **`/usr/local/bin/mediator_add_user`**

  (Support only) Used to add the API user upon installation.

Special Notes

ONTAP Mediator relies on SCST to provide iSCSI (See http://scst.sourceforge.net/index.html). This package is a kernel module that is compiled during installation specifically for the kernel. Any updates to the kernel might require SCST to be re-installed. Alternatively, uninstall then re-install ONTAP Mediator, then reconfigure the ONTAP relationship.

> Any updates to the server OS kernel should be coordinated with a maintenance window in ONTAP.

What's new in ONTAP Mediator

New enhancements to ONTAP Mediator are provided with each release. Here's what's new.

Enhancements

For SCST version information, see the SCST support matrix.

ONTAP Mediator version	Enhancements

1.10	• Support for RHEL: ◦ Compatible: 9.5. ◦ Recommended: 10.0, 9.6, 9.4, and 8.10. • Support for Rocky Linux 10.0, 9.6, and 8.10. • Upgraded the base Python version from Python 3.9 to Python 3.12.
1.9.1	• Support for RHEL: ◦ Compatible: 9.3, 9.1, 8.9, 8.7, 8.6, 8.5, and 8.4. ◦ Recommended: 9.5, 9.4, 9.2, 9.0, 8.10, and 8.8. • Support for Rocky Linux 9.5 and 8.10. • Added new certificates for code signature verification. • Added support for skipping code signature checks using the `-skip-code -signature-check` flag. • Includes installer warnings when expired code signature certificates are detected.
1.9	• Support for RHEL: ◦ Compatible: 9.3, 9.1, 8.9, 8.7, 8.6, 8.5, and 8.4. ◦ Recommended: 9.5, 9.4, 9.2, 9.0, 8.10, and 8.8. • Support for Rocky Linux 9.5 and 8.10. • FIPS support for RHEL and Rocky Linux. • Added performance enhancements for larger scalability. • Improved filenames to simplify the setup of PKI-signed certificates.
1.8	• Support for RHEL: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4. ◦ Recommended: 9.4, 9.3, 9.2, 9.1, 9.0, 8.10, 8.9, and 8.8. • Support for Rocky Linux 9.4 and 8.10.
1.7	• Support for RHEL: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4. ◦ Recommended: 9.3, 9.2, 9.1, 9.0, 8.9, and 8.8. • Support for Rocky Linux 9.3 and 8.9. • Support for SAN (Subject Alternative Name) data in self-signed certificates and third-party signed certificates.

1.6	• Python 3.9 updates.
	• Support for RHEL:
	  ◦ Compatible: 8.7, 8.6, 8.5, and 8.4.
	  ◦ Recommended: 9.2, 9.1, 9.0, and 8.8.
	• Support for Rocky Linux 9.2 and 8.8.
	• Discontinued support for RHEL 7.x / CentOS all releases.

1.5	• Support for RHEL 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6. • Support for CentOS 7.9, 7.8, 7.7, and 7.6. • Includes deprecation warnings for RHEL 7.x / CentOS 7.x. • Optimizes speed for larger scale SnapMirror active sync systems. • Cryptographic code-signature added to the installer.
1.4	• Support for RHEL 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6. • Support for CentOS 7.9, 7.8, 7.7, and 7.6. • Added support for UFEI-based firmware's Secure Boot (SB).
1.3	• Support for RHEL 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6. • Support for CentOS 7.9, 7.8, 7.7, and 7.6.
1.2	• Support for RHEL 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6. • Support for CentOS 7.9, 7.8, 7.7, and 7.6. • Support for HTTPs mailboxes. • For use with ONTAP 9.8+ MCC-IP AUSO and SnapMirror active sync ZRTO.
1.1	• Support for RHEL 8.0 and 7.6. • Support for CentOS 7.6. • Eliminates Perl dependencies.
1.0	• Support for iSCSI mailboxes. • For use with ONTAP 9.7+ MCC-IP AUSO. • Support for RHEL/CentOS 7.6.

OS support matrix

OS for ONTAP Mediator	1.10	1.9.1	1.9	1.8	1.7	1.6	1.5	1.4	1.3	1.2	1.1	1.0

RHEL 10.0	Yes	Yes	No	No	No	No	No	No	No	No	No	No
RHEL 9.6	Yes	Yes	No	No	No	No	No	No	No	No	No	No

RHEL 8.4	No	Compatible	Compatible	Yes	Yes	Yes	Yes	Yes	No	No	No	No
RHEL 8.3	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	No	No	No

RHEL 8.2	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	No	No	No
RHEL 8.1	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	Yes	No	No
RHEL 8.0	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	Yes	Yes	No
RHEL and CentOS 7.9	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	Compatible	No	No
RHEL and CentOS 7.8	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	Yes	No	No
RHEL and CentOS 7.7	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	Yes	No	No
RHEL and CentOS 7.6	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Obsolete	Yes	Yes	Yes	Yes	Yes	Yes (RHEL only)
CentOS 8 and stream	No	No	No	No	No	No	No	No	No	N/A	N/A	N/A
Rocky Linux 10.0	Yes	No	No	No	No	No	No	No	No	No	No	No
Rocky Linux 9	Yes	Yes	Yes	Yes	Yes	Yes	N/A	N/A	N/A	N/A	N/A	N/A
Rocky Linux 8	Yes	Yes	Yes	Yes	Yes	Yes	N/A	N/A	N/A	N/A	N/A	N/A
Oracle Linux 10	No	No	No	No	No	No	No	No	No	No	No	No

Oracle Linux 9	No	No	No	No	No	No	No	No	No	No	No	No

- "Yes" means that the OS is recommended for ONTAP Mediator installation and is fully compatible and supported.
- "No" means that the OS and ONTAP Mediator are not compatible.
- "Compatible" means that Red Hat no longer supports these RHEL versions, but ONTAP Mediator can still be installed on them.
- ONTAP Mediator 1.6 adds support for Rocky Linux 9 and 8.
- ONTAP Mediator 1.5 was the last supported release for RHEL 7.x branch operating systems.
- Centos 8 was removed for all releases due to its rebranching. Centos Stream was deemed as not a suitable production target OS. No support is planned.

SCST support matrix

The following table shows the supported SCST version for each version of ONTAP Mediator.

ONTAP Mediator version	Supported SCST version
ONTAP Mediator 1.10	scst-3.9.tar.gz
ONTAP Mediator 1.9.1	scst-3.8.0.tar.bz2
ONTAP Mediator 1.9	scst-3.8.0.tar.bz2
ONTAP Mediator 1.8	scst-3.8.0.tar.bz2
ONTAP Mediator 1.7	scst-3.7.0.tar.bz2
ONTAP Mediator 1.6	scst-3.7.0.tar.bz2
ONTAP Mediator 1.5	scst-3.6.0.tar.bz2
ONTAP Mediator 1.4	scst-3.6.0.tar.bz2
ONTAP Mediator 1.3	scst-3.5.0.tar.bz2
ONTAP Mediator 1.2	scst-3.4.0.tar.bz2
ONTAP Mediator 1.1	scst-3.4.0.tar.bz2
ONTAP Mediator 1.0	scst-3.3.0.tar.bz2

Install or upgrade

ONTAP Mediator installation workflow summary

Installing ONTAP Mediator includes preparing for the installation, providing access to repositories, downloading the installation package, verifying the code signature, installing the ONTAP Mediator package, and performing post-installation configuration tasks.

1 Prepare to install or upgrade ONTAP Mediator

To install or upgrade ONTAP Mediator, you must ensure all prerequisites are met.

2 **Upgrade host OS and Mediator**

If you are upgrading and existing version of ONTAP Mediator, you must first uninstall the previous version, and then install the new version. If you are installing ONTAP Mediator for the first time, you can skip this step.

3 **Provide repository access**

You should enable access to repositories so that ONTAP Mediator can access the required packages during the installation process.

4 **Download the ONTAP Mediator installation package**

Download the ONTAP Mediator installation package from the ONTAP Mediator download page.

5 **Verify the code signature of the ONTAP Mediator installation package**

NetApp recommends verifying the ONTAP Mediator code signature before installing the ONTAP Mediator installation package.

6 **Install ONTAP Mediator**

To install ONTAP Mediator, you must get the installation package and run the installer on the host.

7 **Verify the ONTAP Mediator installation**

After you install ONTAP Mediator, verify that it is running successfully.

8 **Perform post-installation configuration tasks**

After ONTAP Mediator is installed and running, additional configuration tasks must be performed to use the ONTAP Mediator features.

Prepare to install or upgrade ONTAP Mediator

To install ONTAP Mediator, you must ensure all prerequisites are met, fetch the installation package, and run the installer on the host. This procedure is used for an installation or an upgrade of an existing installation.

- Beginning with ONTAP 9.8, you can use any version of ONTAP Mediator to monitor an SnapMirror active sync relationship.
- Beginning with ONTAP 9.7, you can use any version of ONTAP Mediator to monitor a MetroCluster IP configuration.

Installation and upgrade considerations

Review the following considerations before you upgrade or install ONTAP Mediator.

> ⓘ ONTAP Mediator 1.8 and earlier is not compatible with Red Hat Enterprise Linux (RHEL) FIPS mode and will prevent it from installing successfully. You can check if FIPS mode is enabled using the `fips-mode-setup --check` command. You can disable FIPS mode using the `fips-modesetup --disable` command. Reboot after disabling FIPS mode to successfully install ONTAP Mediator 1.8 or earlier.

- You should upgrade ONTAP Mediator to the latest version that is available. Previous versions of ONTAP Mediator remain backwards compatible with all ONTAP versions but recent versions include security patches for all third-party elements.
- When you upgrade to a new ONTAP Mediator version, the installer automatically upgrades to the recommended SCST version unless a higher version is available. For instructions on manually installing a higher SCST version, see Manage ONTAP Mediator. For supported versions, see the SCST support matrix.

> ⓘ
> - If an installation failure occurs, you might need to upgrade to a later version of ONTAP Mediator.
> - From June 15, 2025, you can't install or upgrade ONTAP Mediator 1.9 and 1.8 because their code signing certificates have expired. If the installation or upgrade fails, use the ONTAP Mediator 1.9.1 patch version instead.

- If you install the `yum-utils` package, you can use the `needs-restarting` command.
- ONTAP Mediator 1.10 and earlier versions do not support IPv6.

Host requirements

Follow these requirements when installing RHEL or Rocky Linux and configuring the associated repositories.

> ⓘ If you modify the installation or configuration process, you might need to perform additional steps.

Linux distribution requirements

- Install RHEL or Rocky Linux according to Red Hat's best practices. Since CentOS 8.x has reached end-of-life, compatible versions of CentOS 8.x are not recommended.
- When installing ONTAP Mediator, ensure the system has access to the required repository so the installation program can retrieve and install all required software dependencies.
- To enable the yum installer to find dependent software in the RHEL repositories, register the system during installation or afterwards using a valid Red Hat subscription.

  > ⓘ See the Red Hat Subscription Manager documentation for further information.

Networking requirements

Ensure that the following ports are available and unused for ONTAP Mediator:

Port/services	Source	Direction	Destination	Purpose

22/tcp	Management host	Inbound	ONTAP Mediator	(Optional) SSH / ONTAP Mediator management
31784/tcp	Cluster management LIFs	Inbound	ONTAP Mediator web server	(Required) REST API (HTTPS)
3260/tcp [1]	Node Data LIFs or Node Management LIFs	Bidirectional	ONTAP Mediator iSCSI targets	(Required for MCCIP) iSCSI data connection for mailboxes

1. For SMBC customers, ONTAP doesn't require port 3260 to be enabled or connected.
   - If using a third-party firewall, refer to Firewall requirements for ONTAP Mediator.
   - For Linux hosts without internet access, make sure the required packages are available in a local repository.

     If you are using Link Aggregation Control Protocol (LACP) in a Linux environment, configure the kernel and set the `sysctl net.ipv4.conf.all.arp_ignore` to `2`.

OS requirements

Your OS must meet the following requirements:

- 64-bit physical installation or virtual machine
- 8 GB RAM
- 1 GB disk space (used for applications installation, server logs, and the database)
- User: Root access

The following table shows the supported OSs for each version of ONTAP Mediator.

ONTAP Mediator version	Supported Linux versions
1.10	• Red Hat Enterprise Linux ◦ Compatible: 9.5 [1] ◦ Recommended: 10, 9.6, 9.4, and 8.10 • Rocky Linux 10, 9.6, and 8.10
1.9.1	• Red Hat Enterprise Linux ◦ Compatible: 9.3, 9.1, 8.9, 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.5, 9.4, 9.2, 9.0, 8.10, and 8.8 • Rocky Linux 9.5 and 8.10

1.9	• Red Hat Enterprise Linux ◦ Compatible: 9.3, 9.1, 8.9, 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.5, 9.4, 9.2, 9.0, 8.10, and 8.8 • Rocky Linux 9.5 and 8.10
1.8	• Red Hat Enterprise Linux: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.4, 9.3, 9.2, 9.1, 9.0, 8.10, 8.9, and 8.8 • Rocky Linux 9.4 and 8.10
1.7	• Red Hat Enterprise Linux: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.3, 9.2, 9.1, 9.0, 8.9, and 8.8 • Rocky Linux 9.3 and 8.9
1.6	• Red Hat Enterprise Linux: ◦ Compatible: 8.7, 8.6, 8.5, and 8.4 [1] ◦ Recommended: 9.2, 9.1, 9.0, and 8.8 • Rocky Linux 9.2 and 8.8
1.5	• Red Hat Enterprise Linux: 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6
1.4	• Red Hat Enterprise Linux: 8.5, 8.4, 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6
1.3	• Red Hat Enterprise Linux: 8.3, 8.2, 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6
1.2	• Red Hat Enterprise Linux: 8.1, 8.0, 7.9, 7.8, 7.7, and 7.6 • CentOS: 7.9, 7.8, 7.7, and 7.6

1. Compatible means that Red Hat no longer supports these RHEL versions, but ONTAP Mediator can still be installed on them.

OS required packages

The following packages are required by ONTAP Mediator:

> ⓘ The packages are either pre-installed or automatically installed by the ONTAP Mediator installer.

All RHEL/CentOS versions	Additional packages for RHEL 10.x / Rocky Linux 10	Additional packages for RHEL 9.x / Rocky Linux 9	Additional packages for RHEL 8.x / Rocky Linux 8
• openssl • openssl-devel • kernel-devel-$(uname -r) • gcc • make • libselinux-utils • patch • bzip2 • perl-Data-Dumper • perl-ExtUtils-MakeMaker • efibootmgr • mokutil	• python3.12 • python3.12-devel	• elfutils-libelf-devel • policycoreutils-python-utils • python3 • python3-devel	• elfutils-libelf-devel • policycoreutils-python-utils • redhat-lsb-core • python39 • python39-devel

The Mediator installation package is a self-extracting compressed tar file that includes:

- An RPM file containing all dependencies that cannot be obtained from the supported release's repository.
- An install script.

A valid SSL certification is recommended.

OS upgrade considerations and kernel compatibility

- All library packages, except the kernel, can safely be updated but might require a reboot to apply the changes within the ONTAP Mediator application. A service window is recommended when a reboot is required.
- You should keep the OS kernel up to date. The kernel core can be upgraded to a version listed as supported in the ONTAP Mediator version matrix. A reboot is mandatory, so you should plan a maintenance window for the outage.
  - You must uninstall the SCST kernel module before rebooting and then re-install it after.
  - You must have a supported version of the SCST ready to reinstall before starting the kernel OS upgrade.

> - The kernel version must match the operating system version.
> - Upgrading to a kernel beyond the supported OS release for the specific ONTAP Mediator release is not supported. (This likely indicates that the tested SCST module won't compile).

Install ONTAP Mediator when UEFI Secure Boot is enabled

ONTAP Mediator can be installed on a system with or without UEFI Secure Boot enabled.

About this task

You can choose to disable UEFI Secure Boot before installing ONTAP Mediator if it is not needed or if you are troubleshooting ONTAP Mediator installation issues. Disable the UEFI Secure Boot option from your machine settings.

> For detailed instructions on disabling UEFI Secure Boot, refer to the documentation for your host OS.

To install ONTAP Mediator with UEFI Secure Boot enabled, you must register a security key before the service can start. The key is generated during the SCST installation's compile step and saved as a private-public key pair on your machine. Use the `mokutil` utility to add the public key as a Machine Owner Key (MOK) to your UEFI firmware, enabling the system to trust and load the signed module. Save the `mokutil` passphrase in a secure location as this is required when rebooting your system to activate the MOK.

Steps

1. Check if UEFI Secure Boot is enabled on your system:

```
mokutil --sb-state
```

The results indicate whether UEFI Secure Boot is enabled on this system.

If…	Go to…
UEFI secure boot is enabled	The step where you run the `mokutil` utility
UEFI secure boot is disabled	Upgrade the host operating system and then ONTAP Mediator

> ◦ You are prompted to create a passphrase that you must store in a secure location. You'll need this passphrase to enable the key in the UEFI Boot Manager.
>
> ◦ ONTAP Mediator 1.2.0 and earlier versions do not support this mode.

2. If the `mokutil` utility is not installed, run the following command:

```
yum install mokutil
```

3. Add the public key to the MOK list:

```
mokutil --import
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/scst_module_key.de
r
```

> You can leave the private key in its default location or move it to a secure location. However, the public key must be maintained in its existing location for use by the Boot Manager. For further information, see the following README.module-signing file:

```
[root@hostname ~]# ls
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/
README.module-signing scst_module_key.der scst_module_key.priv
```

4. Reboot the host and use your device's UEFI Boot Manager to approve the new MOK. You'll need the

passphrase provided for the `mokutil` utility in the step where you check if UEFI Secure Boot is enabled on your system.

Upgrade the host OS and ONTAP Mediator

To upgrade the host OS for ONTAP Mediator to a later version, you must first uninstall ONTAP Mediator.

About this task

When you upgrade the host OS for ONTAP Mediator to a later major version (for example, from 7.x to 8.x) using the leapp-upgrade tool, you must uninstall ONTAP Mediator because the tool tries to detect new versions of any RPMs that are installed in the repositories that are registered with the system.

Because an .rpm file was installed as part of the ONTAP Mediator installer, it is included in that search. However, because that .rpm file was unpacked as part of the installer and not downloaded from a registered repository, an upgrade cannot be found. In this case, the leapp-upgrade tool uninstalls the package.

In order to preserve the log files, which will be used to triage support cases, you should back up the files before you upgrade the OS and restore them after a reinstall of the ONTAP Mediator package. ONTAP clusters that are connected to it will need to be reconnected after the ONTAP Mediator installation.

> ⓘ The following steps should be performed in order. Immediately after you reinstall ONTAP Mediator, you should stop ontap_mediator, replace the log files, and restart it. This is to ensure that logs are not lost.

Steps

1. Back up the log files.

```
[rootmediator-host ~]# tar -czf ontap_mediator_file_backup.tgz -C
/opt/netapp/lib/ontap_mediator ./log
./ontap_mediator/server_config/ontap_mediator.user_config.yaml
[rootmediator-host ~]# tar -tf ontap_mediator_file_backup.tgz
./log/
./log/ontap_mediator.log
./log/scstadmin.log
./log/ontap_mediator_stdout.log
./log/ontap_mediator_requests.log
./log/install_20230419134611.log
./log/scst.log
./log/ontap_mediator_syslog.log
./ontap_mediator/server_config/ontap_mediator.user_config.yaml
[rootmediator-host ~]#
```

2. Perform upgrade with leapp-upgrade tool.

```
[rootmediator-host ~]# leapp preupgrade --target 8.4
  ..<snip upgrade checks>..
  ..<fix issues found>..
[rootmediator-host ~]# leapp upgrade --target 8.4
  ..<snip upgrade>..
[rootmediator-host ~]# cat /etc/os-release | head -2
NAME="Red Hat Enterprise Linux"
VERSION="8.4 (Ootpa)"
[rootmediator-host ~]#
```

3. Reinstall ONTAP Mediator.

   Perform the rest of the steps immediately after reinstalling ONTAP Mediator to prevent a loss of log files.

```
[rootmediator-host ~]# ontap-mediator-1.10/ontap-mediator-1.10

ONTAP Mediator: Self Extracting Installer

  ..<snip installation>..
[rootmediator-host ~]#
```

4. Stop ontap_mediator.

```
[rootmediator-host ~]# systemctl stop ontap_mediator
[rootmediator-host ~]#
```

5. Replace the log files.

```
[rootmediator-host ~]# tar -xf ontap_mediator_log_backup.tgz -C
/opt/netapp/lib/ontap_mediator
[rootmediator-host ~]#
```

6. Start ontap_mediator.

```
[rootmediator-host ~]# systemctl start ontap_mediator
[rootmediator-host ~]#
```

7. Reconnect all ONTAP clusters to the upgraded ONTAP Mediator

Procedure for SnapMirror active sync

For SnapMirror active sync, if you installed your TLS certificate outside of the /opt/netapp directory, then you will not need to reinstall it. If you were using the default generated self-signed certificate or put your custom certificate in the /opt/netapp directory, then you should back it up and restore it.

```
peer1::> snapmirror mediator show

Provide repository access for ONTAP Mediator installation

You should enable access to repositories so that ONTAP Mediator can access the required packages during the installation process.

Steps

1. Determine which repositories must be accessed, as shown in the following table:

If your operating system is…	You must provide access to these repositories…
RHEL 10.x	• rhel-10-for-x86_64-baseos-rpms • rhel-10-for-x86_64-appstream-rpms
RHEL 9.x	• rhel-9-for-x86_64-baseos-rpms • rhel-9-for-x86_64-appstream-rpms
RHEL 8.x	• rhel-8-for-x86_64-baseos-rpms • rhel-8-for-x86_64-appstream-rpms
RHEL 7.x	• rhel-7-server-optional-rpms
CentOS 7.x	• C7.6.1810 - Base repository
Rocky Linux 10	• appstream • baseos
Rocky Linux 9	• appstream • baseos
Rocky Linux 8	• appstream • baseos

2. Use one of the following procedures to enable access to the repositories listed above so ONTAP Mediator can access the required packages during the installation process.

If ONTAP Mediator has dependencies on Python modules present in the "extras" and "optional" repositories, it might need to access the `rhel-X-for-x86_64-extras-rpms` and `rhel-X-for-x86_64-optional-rpms` files.

Procedure for RHEL 10.x operating system

Use this procedure if your operating system is **RHEL 10.x** to enable access to repositories:

Steps

1. Subscribe to the required repository:

```
subscription-manager repos --enable rhel-10-for-x86_64-baseos-rpms
```

```
subscription-manager repos --enable rhel-10-for-x86_64-appstream-
rpms
```

   The following example shows the execution of this command:

```
[root@localhost ~]# subscription-manager repos --enable rhel-10-for-
x86_64-baseos-rpms
Repository 'rhel-10-for-x86_64-baseos-rpms' is enabled for this
system.
[root@localhost ~]# subscription-manager repos --enable rhel-10-for-
x86_64-appstream-rpms
Repository 'rhel-10-for-x86_64-appstream-rpms' is enabled for this
system.
```

2. Run the `yum repolist` command.

   The newly subscribed repositories should appear in the list.

Procedure for RHEL 9.x operating system

Use this procedure if your operating system is **RHEL 9.x** to enable access to repositories:

Steps

1. Subscribe to the required repository:

```
subscription-manager repos --enable rhel-9-for-x86_64-baseos-rpms
```

```
subscription-manager repos --enable rhel-9-for-x86_64-appstream-rpms
```

The following example shows the execution of this command:

```
[root@localhost ~]# subscription-manager repos --enable rhel-9-for-
x86_64-baseos-rpms
Repository 'rhel-9-for-x86_64-baseos-rpms' is enabled for this
system.
[root@localhost ~]# subscription-manager repos --enable rhel-9-for-
x86_64-appstream-rpms
Repository 'rhel-9-for-x86_64-appstream-rpms' is enabled for this
system.
```

2. Run the `yum repolist` command.

The newly subscribed repositories should appear in the list.

Procedure for RHEL 8.x operating system

Use this procedure if your operating system is **RHEL 8.x** to enable access to repositories:

Steps

1. Subscribe to the required repository:

```
subscription-manager repos --enable rhel-8-for-x86_64-baseos-rpms
```

```
subscription-manager repos --enable rhel-8-for-x86_64-appstream-rpms
```

   The following example shows the execution of this command:

```
[root@localhost ~]# subscription-manager repos --enable rhel-8-for-
x86_64-baseos-rpms
Repository 'rhel-8-for-x86_64-baseos-rpms' is enabled for this
system.
[root@localhost ~]# subscription-manager repos --enable rhel-8-for-
x86_64-appstream-rpms
Repository 'rhel-8-for-x86_64-appstream-rpms' is enabled for this
system.
```

2. Run the `yum repolist` command.

   The newly subscribed repositories should appear in the list.

Procedure for RHEL 7.x operating system

Use this procedure if your operating system is **RHEL 7.x** to enable access to repositories:

Steps

1. Subscribe to the required repository:

```
subscription-manager repos --enable rhel-7-server-optional-rpms
```

   The following example shows the execution of this command:

```
[root@localhost ~]# subscription-manager repos --enable rhel-7-
server-optional-rpms
Repository 'rhel-7-server-optional-rpms' is enabled for this system.
```

2. Run the `yum repolist` command.

   The following example shows the execution of this command. The "rhel-7-server-optional-rpms" repository should appear in the list.

```
[root@localhost ~]# yum repolist
Loaded plugins: product-id, search-disabled-repos, subscription-
manager
rhel-7-server-optional-rpms | 3.2 kB  00:00:00
rhel-7-server-rpms | 3.5 kB  00:00:00
(1/3): rhel-7-server-optional-rpms/7Server/x86_64/group
|  26 kB  00:00:00
(2/3): rhel-7-server-optional-rpms/7Server/x86_64/updateinfo
| 2.5 MB  00:00:00
(3/3): rhel-7-server-optional-rpms/7Server/x86_64/primary_db
| 8.3 MB  00:00:01
repo id                                      repo name
status
rhel-7-server-optional-rpms/7Server/x86_64   Red Hat Enterprise
Linux 7 Server - Optional (RPMs)   19,447
rhel-7-server-rpms/7Server/x86_64            Red Hat Enterprise
Linux 7 Server (RPMs)              26,758
repolist: 46,205
[root@localhost ~]#
```

Procedure for CentOS 7.x operating system

Use this procedure if your operating system is **CentOS 7.x** to enable access to repositories:

> The following examples are showing a repository for CentOS 7.6 and might not work for other CentOS versions. Use the base repository for your version of CentOS.

Steps

1. Add the C7.6.1810 - Base repository. The C7.6.1810 - Base vault repository contains the "kernel-devel" package needed for ONTAP Mediator.
2. Add the following lines to /etc/yum.repos.d/CentOS-Vault.repo.

```
[C7.6.1810-base]
name=CentOS-7.6.1810 - Base
baseurl=http://vault.centos.org/7.6.1810/os/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7
enabled=1
```

3. Run the `yum repolist` command.

   The following example shows the execution of this command. The CentOS-7.6.1810 - Base repository should appear in the list.

```
Loaded plugins: fastestmirror
Loading mirror speeds from cached hostfile
 * base: distro.ibiblio.org
 * extras: distro.ibiblio.org
 * updates: ewr.edge.kernel.org
C7.6.1810-base                                   | 3.6 kB  00:00:00
(1/2): C7.6.1810-base/x86_64/group_gz            | 166 kB  00:00:00
(2/2): C7.6.1810-base/x86_64/primary_db          | 6.0 MB  00:00:04
repo id                      repo name                status
C7.6.1810-base/x86_64        CentOS-7.6.1810 - Base   10,019
base/7/x86_64                CentOS-7 - Base          10,097
extras/7/x86_64              CentOS-7 - Extras        307
updates/7/x86_64             CentOS-7 - Updates       1,010
repolist: 21,433
[root@localhost ~]#
```

Procedure for Rocky Linux 10, 9, or 8 operating systems

Use this procedure if your operating system is **Rocky Linux 10**, **Rocky Linux 9**, or **Rocky Linux 8** to enable access to repositories:

Steps

1. Subscribe to the required repositories:

```
dnf config-manager --set-enabled baseos
```

```
dnf config-manager --set-enabled appstream
```

2. Perform a `clean` operation:

```
dnf clean all
```

3. Verify the list of repositories:

```
dnf repolist
```

Example for Rocky Linux 10

```
[root@localhost ~]# dnf config-manager --set-enabled baseos
[root@localhost ~]# dnf config-manager --set-enabled appstream
[root@localhost ~]# dnf clean all
[root@localhost ~]# dnf repolist
repo id                         repo name
appstream                       Rocky Linux 10 - AppStream
baseos                          Rocky Linux 10 - BaseOS
[root@localhost ~]#
```

Example for Rocky Linux 9

```
[root@localhost ~]# dnf config-manager --set-enabled baseos
[root@localhost ~]# dnf config-manager --set-enabled appstream
[root@localhost ~]# dnf clean all
[root@localhost ~]# dnf repolist
repo id                         repo name
appstream                       Rocky Linux 9 - AppStream
baseos                          Rocky Linux 9 - BaseOS
[root@localhost ~]#
```

Example for Rocky Linux 8

```
[root@localhost ~]# dnf config-manager --set-enabled baseos
[root@localhost ~]# dnf config-manager --set-enabled appstream
[root@localhost ~]# dnf clean all
[root@localhost ~]# dnf repolist
repo id                        repo name
appstream                      Rocky Linux 8 - AppStream
baseos                         Rocky Linux 8 - BaseOS
[root@localhost ~]#
```

Download the ONTAP Mediator installation package

Download the ONTAP Mediator installation package as part of the installation process.

Steps

1. Download the ONTAP Mediator installation package from the ONTAP Mediator download page.

   ONTAP Mediator download page

2. Confirm that the Mediator installation package is in the current working directory:

   ```
   [root@sdot-r730-0003a-d6 ~]# ls ontap-mediator-1.10.tgz
   ```

   ```
   ontap-mediator-1.10.tgz
   ```

   For ONTAP Mediator versions 1.4 and earlier, the installer is named `ontap-mediator`.

   If you are at a location without access to the internet, you must ensure that the installer has access to the required packages.

3. If necessary, move the Mediator installation package from the download directory to the installation directory on the Linux Mediator host.

4. Unzip the installer package:

   ```
   tar xvfz ontap-mediator-1.10.tgz
   ```

```
ontap-mediator-1.10/
ontap-mediator-1.10/csc-prod-ONTAP-Mediator.pem
ontap-mediator-1.10/csc-prod-chain-ONTAP-Mediator.pem
ontap-mediator-1.10/tsa-prod-ONTAP-Mediator.pem
ontap-mediator-1.10/tsa-prod-chain-ONTAP-Mediator.pem
ontap-mediator-1.10/ONTAP-Mediator-production.pub
ontap-mediator-1.10/ontap-mediator-1.10
ontap-mediator-1.10/ontap-mediator-1.10.sig.tsr
ontap-mediator-1.10/ontap-mediator-1.10.tsr
ontap-mediator-1.10/ontap-mediator-1.10.sig
```

Verify the ONTAP Mediator code signature

NetApp recommends verifying the ONTAP Mediator code signature before installing the ONTAP Mediator installation package; however, this process is optional.

Before you begin

Before verifying the ONTAP Mediator code signature, your system must meet the following requirements.

> - From June 15th, 2025, you can't install or upgrade to ONTAP Mediator 1.9 and 1.8 because the code signature verification certificates have expired. Instead, install or upgrade to ONTAP Mediator 1.10.
> - If the system doesn't meet the below requirements, the verification process isn't required and you can go directly to Install the ONTAP Mediator installation package.

- openssl versions 1.0.2 to 3.0 for basic verification
- openssl version 1.1.0 or later for Time Stamping Authority (TSA) operations
- Public internet access for OCSP verification

The following files are included in the download package:

File	Description
`ONTAP-Mediator-production.pub`	The public key used to verify the signature
`csc-prod-chain-ONTAP-Mediator.pem`	The public certification CA chain of trust
`csc-prod-ONTAP-Mediator.pem`	The certificate used to generate the key
`ontap-mediator-1.10`	The product installation executable for version 1.10
`ontap-mediator-1.10.sig`	The SHA-256 hashed, then RSA-signed using the csc-prod key, signature for the installer

`ontap-mediator-1.10.sig.tsr`	The revocation request for use by OCSCP for the installer's signature
`ontap-mediator-1.10.tsr`	The timestamp signing request file
`tsa-prod-ONTAP-Mediator.pem`	The public certificate for the TSR
`tsa-prod-chain-ONTAP-Mediator.pem`	The public certificate CA Chain for the TSR

Steps

1. Perform the revocation check on `csc-prod-ONTAP-Mediator.pem` by using Online Certificate Status Protocol (OCSP).

   a. Find the OCSP URL used to register the certificate because developer certificates might not provide a uri.

   ```
   openssl x509 -noout -ocsp_uri -in csc-prod-chain-ONTAP-Mediator.pem
   ```

   b. Generate an OCSP request for the certificate.

   ```
   openssl ocsp -issuer csc-prod-chain-ONTAP-Mediator.pem -CAfile csc-
   prod-chain-ONTAP-Mediator.pem -cert csc-prod-ONTAP-Mediator.pem
   -reqout req.der
   ```

   c. Connect to the OCSP Manager to send the OCSP request:

   ```
   openssl ocsp -issuer csc-prod-chain-ONTAP-Mediator.pem -CAfile csc-
   prod-chain-ONTAP-Mediator.pem -cert csc-prod-ONTAP-Mediator.pem  -url
   ${ocsp_uri} -resp_text -respout resp.der -verify_other csc-prod-
   chain-ONTAP-Mediator.pem
   ```

2. Verify the trust chain of the CSC and expiration dates against the local host:

   `openssl verify`

   The `openssl` version from the PATH must have a valid `cert.pem` (not self-signed).

```
openssl verify -untrusted csc-prod-chain-ONTAP-Mediator.pem -CApath
${OPENSSLDIR} csc-prod-ONTAP-Mediator.pem  # Failure action: The Code-
Signature-Check certificate has expired or is invalid. Download a newer
version of the ONTAP Mediator.
openssl verify -untrusted tsa-prod-chain-ONTAP-Mediator.pem -CApath
${OPENSSLDIR} tsa-prod-ONTAP-Mediator.pem  # Failure action: The Time-
Stamp certificate has expired or is invalid. Download a newer version of
the ONTAP Mediator.
```

3. Verify the `ontap-mediator-1.10.sig.tsr` and `ontap-mediator-1.10.tsr` files using the associated certificates:

   `openssl ts -verify`

   > `.tsr` files contain the time stamp response associated with the installer and the code signature. Processing confirms that the time stamp has a valid signature from TSA and that your input file has not changed.
   > The verification is performed locally on your machine. Independently, there is no need to access TSA servers.

```
openssl ts -verify -data ontap-mediator-1.10.sig -in ontap-mediator-
1.10.sig.tsr -CAfile tsa-prod-chain-ONTAP-Mediator.pem -untrusted tsa-
prod-ONTAP-Mediator.pem
openssl ts -verify -data ontap-mediator-1.10 -in ontap-mediator-1.10.tsr
-CAfile tsa-prod-chain-ONTAP-Mediator.pem -untrusted tsa-prod-ONTAP-
Mediator.pem
```

4. Verify signatures against the key:

   `openssl -dgst -verify`

```
openssl dgst -sha256 -verify ONTAP-Mediator-production.pub -signature
ontap-mediator-1.10.sig ontap-mediator-1.10
```

Example of verifying the ONTAP Mediator code signature (console output)

```
[root@scspa2695423001 ontap-mediator-1.10]# pwd
/root/ontap-mediator-1.10
[root@scspa2695423001 ontap-mediator-1.10]# ls -l

[root@scspa2695423001 ontap-mediator-1.10]#
```

Install the ONTAP Mediator installation package

To install ONTAP Mediator, you must get the installation package and run the installer on the host.

Steps

1. Run the installer and respond to the prompts as required:

   `./ontap-mediator-1.10/ontap-mediator-1.10 -y`

   ```
   [root@scs000099753 ~]# ./ontap-mediator-1.10/ontap-mediator-1.10 -y
   ```

   > To skip the automatic signature check during installation, use the following command: `./ontap-mediator-1.10/ontap-mediator-1.10 -y --skip-code-signature -check`

   The installation process proceeds to create the required accounts and install required packages. If you have a previous version of Mediator installed on the host, you will be prompted to confirm that you want to upgrade.

2. Beginning with ONTAP Mediator 1.4, the Secure Boot mechanism is enabled on UEFI systems. When Secure Boot is enabled, you must take additional steps to register the security key after installation:

   - Follow instructions in the README file to sign the SCST kernel module.:

```
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/README.module-signing
```

- Locate the required keys:

```
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys
```

> After installation, the README files and key location are also provided in the system output.

Example of ONTAP Mediator installation (console output)

```
[root@mediator_host ~]# tar -zxvf ontap-mediator-1.10.tgz
ontap-mediator-1.10/
ontap-mediator-1.10/csc-prod-chain-ONTAP-Mediator.pem
ontap-mediator-1.10/csc-prod-ONTAP-Mediator.pem
ontap-mediator-1.10/tsa-prod-ONTAP-Mediator.pem
ontap-mediator-1.10/tsa-prod-chain-ONTAP-Mediator.pem
ontap-mediator-1.10/ONTAP-Mediator-production.pub
ontap-mediator-1.10/ontap-mediator-1.10
ontap-mediator-1.10/ontap-mediator-1.10.sig.tsr
ontap-mediator-1.10/ontap-mediator-1.10.tsr
ontap-mediator-1.10/ontap-mediator-1.10.sig
[root@mediator_host ~]#./ontap-mediator-1.10.0/ontap-mediator-1.10.0

ONTAP Mediator: Self Extracting Installer

+ Extracting the ONTAP Mediator installation/upgrade archive
+ Performing the ONTAP Mediator run-time code signature check
   Using openssl from the path: /usr/bin/openssl configured for

 SKIPPING: Code signature check, manual override due to lack of OCSP
response
+ Unpacking the ONTAP Mediator installer

ONTAP Mediator requires two user accounts. One for the service
(netapp), and one for use by ONTAP to the mediator API (mediatoradmin).
Using default account names: netapp + mediatoradmin

Enter ONTAP Mediator user account (mediatoradmin) password:

Re-Enter ONTAP Mediator user account (mediatoradmin) password:
```

```
+ Checking if SELinux is in enforcing mode
The installer will change the SELinux context type of
/opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi from type 'lib_t' to
'bin_t'.

+ Checking for default Linux firewall

+ Installing required packages.

Updating Subscription Management repositories.

```
    ONTAP Mediator rsyslog and logging rotation enabled
+ Install successful. (Moving log to
/opt/netapp/lib/ontap_mediator/log/install_20250715160240.log)
+ WARNING: This system supports UEFI
           Secure Boot (SB) is currently disabled on this system.
           If SB is enabled in the future, SCST will not work unless
the following action is taken:
           Using the keys in
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys follow
           instructions in
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/README.modu
le-signing
           to sign the SCST kernel module. Note that reboot will be
needed.
     SCST will not start automatically when Secure Boot is enabled and
not configured properly.

+ Note: ONTAP Mediator generated a self-signed server certificate for
temporary use on
    this host. If the DNS name or IP address for the host is changed,
the certificate
    will no longer be valid. The default certificates should be
replaced with secure
    trusted certificates signed by a known certificate authority prior
to use for production.
    For more information, see /opt/netapp/lib/ontap_mediator/README

+ Note: ONTAP Mediator uses a kernel module compiled specifically for
the current
        OS. Using 'yum update' to upgrade the kernel might cause
service interruption.
    For more information, see /opt/netapp/lib/ontap_mediator/README
root@mediator_host:~# systemctl status ontap_mediator
● ontap_mediator.service - ONTAP Mediator
     Loaded: loaded (/etc/systemd/system/ontap_mediator.service;

Verify the ONTAP Mediator installation status

After you install ONTAP Mediator, verify that it is running successfully.

Steps

1. View the status of ONTAP Mediator:
   a. `systemctl status ontap_mediator`

```
[root@scspr1915530002 ~]# systemctl status ontap_mediator

 ontap_mediator.service - ONTAP Mediator
Loaded: loaded (/etc/systemd/system/ontap_mediator.service; enabled;
vendor preset: disabled)
Active: active (running) since Mon 2022-04-18 10:41:49 EDT; 1 weeks 0
days ago
Process: 286710 ExecStop=/bin/kill -s INT $MAINPID (code=exited,
status=0/SUCCESS)
Main PID: 286712 (uwsgi)
Status: "uWSGI is ready"
Tasks: 3 (limit: 49473)
Memory: 139.2M
CGroup: /system.slice/ontap_mediator.service
      ├─286712 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
      ├─286716 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
      └─286717 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini

[root@scspr1915530002 ~]#
```

b. `systemctl status mediator-scst`

```
[root@scspr1915530002 ~]# systemctl status mediator-scst
   Loaded: loaded (/etc/systemd/system/mediator-scst.service;
enabled; vendor preset: disabled)
   Active: active (running) since Mon 2022-04-18 10:41:47 EDT; 1
weeks 0 days ago
  Process: 286595 ExecStart=/etc/init.d/scst start (code=exited,
status=0/SUCCESS)
 Main PID: 286662 (iscsi-scstd)
    Tasks: 1 (limit: 49473)
   Memory: 1.2M
   CGroup: /system.slice/mediator-scst.service
           └─286662 /usr/local/sbin/iscsi-scstd

[root@scspr1915530002 ~]#
```

2. Confirm the ports that are used by ONTAP Mediator:

   `netstat`

```
[root@scspr1905507001 ~]# netstat -anlt | grep -E '3260|31784'

         tcp   0   0 0.0.0.0:31784   0.0.0.0:*      LISTEN

         tcp   0   0 0.0.0.0:3260    0.0.0.0:*      LISTEN

         tcp6  0   0 :::3260         :::*           LISTEN
```

Post-installation ONTAP Mediator configuration

After ONTAP Mediator is installed and running, additional configuration tasks must be performed in the ONTAP storage system to use the ONTAP Mediator features:

- To use ONTAP Mediator in a MetroCluster IP configuration, see Configure ONTAP Mediator from a MetroCluster IP configuration.
- To use SnapMirror active sync, see Install ONTAP Mediator and confirm the ONTAP cluster configuration.

Configure ONTAP Mediator security policies

ONTAP Mediator supports several configurable security settings. The default values for all settings are provided in a `low_space_threshold_mib: 10` read-only file:

`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.user_config.yaml`

All values that are placed in the `ontap_mediator.user_config.yaml` will override the default values and be maintained across all ONTAP Mediator upgrades.

After you modify `ontap_mediator.user_config.yaml`, restart ONTAP Mediator:

```
systemctl restart ontap_mediator
```

Modify ONTAP Mediator attributes

The ONTAP Mediator attributes described in this section can be modified if required.

> Other default values in the `ontap_mediator.config.yaml` should not be changed because modified values are not maintained during ONTAP Mediator upgrades.

You modify ONTAP Mediator attributes by copying the required variables to the `ontap_mediator.user_config.yaml` file to override the default settings.

Install third-party SSL certificates

If you need to replace the default self-signed certificates with third-party SSL certificates, modify certain attributes in the following files:

- `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.config.yaml`

* `/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini`

The variables in these files are used to control the certificate files used by ONTAP Mediator.

ONTAP Mediator 1.9 and later

The default variables listed in the following table are included in the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.config.yaml` file.

Variable	Path
`cert_path`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.crt`
`key_path`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.key`
`ca_cert_path`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/intermediate.crt`
`ca_key_path`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/intermediate.key`
`ca_serial_path`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/intermediate.srl`
`cert_valid_days`	`1095`
`x509_passin_pwd`	`pass:ontap`

- `cert_valid_days` is used to set the expiration of client certificates. The maximum value is three years (1095 days).
- `x509_passin_pwd` is the passphrase for the signed client certificate.

The default variables listed in the following table are included in the `/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini` file.

Variable	Path
`mediator_cert`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.crt`
`mediator_key`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.key`
`ca_cert_path`	`/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/intermediate.crt`

ONTAP Mediator 1.8 and earlier

The default variables listed in the following table are included in the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.config.yaml` file.

Variable	Path
cert_path	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.crt
key_path	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.key
ca_cert_path	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.crt
ca_key_path	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.key
ca_serial_path	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.srl
cert_valid_days	1095
x509_passin_pwd	pass:ontap

- `cert_valid_days` is used to set the expiration of client certificates. The maximum value is three years (1095 days).
- `x509_passin_pwd` is the passphrase for the signed client certificate.

The default variables listed in the following table are included in the `/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini` file.

Variable	Path
mediator_cert	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.crt
mediator_key	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.key
ca_cert_path	/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.crt

If you modify these attributes, restart ONTAP Mediator to apply the changes. For detailed instructions on how to replace default certificates with third-party certificates, refer to Replace self-signed certificates with trusted third party certificates.

Password attack protection

The following settings provide protection against brute-force password guessing attacks.

To enable the feature, set a value for the `window_seconds` and the `retry_limit`.

Examples:

* Provide a 5-minute window for guesses, and then reset the count to zero failures:

  `authentication_lock_window_seconds: 300`

* Lock the account if five failures occur within the window timeframe:

  `authentication_retry_limit: 5`

* Reduce the impact of brute-force password guessing attacks by setting a delay that occurs prior to rejecting each attempt, which slows the attacks.

  `authentication_failure_delay_seconds: 5`

```
authentication_failure_delay_seconds: 0   # seconds (float) to delay
failed auth attempts prior to response, 0 = no delay
authentication_lock_window_seconds: null  # seconds (int) since the
oldest failure before resetting the retry counter, null = no window
authentication_retry_limit: null          # number of retries to allow
before locking API access, null = unlimited
```

Password complexity rules

The following fields control the password complexity rules of the ONTAP Mediator API user account.

```
password_min_length: 8

password_max_length: 64

password_uppercase_chars: 0    # min. uppercase characters

password_lowercase_chars: 1    # min. lowercase character

password_special_chars: 1      # min. non-letter, non-digit

password_nonletter_chars: 2    # min. non-letter characters (digits,
specials, anything)
```

Control of free space

There are settings that control the required free space on the `/opt/netapp/lib/ontap_mediator` disk.

If the space is lower than the set threshold, the service will issue a warning event.

```
low_space_threshold_mib: 10
```

Control of reserve log space

The RESERVE_LOG_SPACE is controlled by specific settings. By default, the ONTAP Mediator installation creates a separate disk space for the logs. The installer creates a new fixed-size file with a total of 700MB of disk space to be used explicitly for ONTAP Mediator logging.

To disable this feature and use the default disk space, perform the following steps:

1. Change the value of RESERVE_LOG_SPACE from 1 to 0 in the following file:

   `/opt/netapp/lib/ontap_mediator/tools/mediator_env`

2. Restart the Mediator:

   a. `cat /opt/netapp/lib/ontap_mediator/tools/mediator_env | grep "RESERVE_LOG_SPACE"`

      ```
      RESERVE_LOG_SPACE=0
      ```

   b. `systemctl restart ontap_mediator`

To re-enable the feature, change the value from 0 to 1 and restart the Mediator.

> Toggling between disk spaces does not purge existing logs. All previous logs are backed up and then moved to the current disk space after toggling and restarting the Mediator.

Manage ONTAP Mediator

Manage ONTAP Mediator, including changing user credentials, stopping and re-enabling the service, verifying its health, and installing or uninstalling SCST for host maintenance. You can also manage certificates, such as regenerating self-signed certificates, replacing them with trusted third-party certificates, and troubleshooting certificate-related issues.

Change the username

You can change the username using the following procedure.

About this task

Perform this task on the Linux host where you installed ONTAP Mediator.

If you are unable to reach this command, you might need to run the command using the full path as shown in the following example:

`/usr/local/bin/mediator_username`

Steps

Change the username by choosing one of the following options:

- **Option (a)**: Run the command `mediator_change_user` and respond to the prompts as shown in the following example:

```
[root@mediator-host ~]# mediator_change_user
Modify the Mediator API username by entering the following values:
    Mediator API User Name: mediatoradmin
                  Password:
New Mediator API User Name: mediator
The account username has been modified successfully.
[root@mediator-host ~]#
```

- **Option (b)**: Run the following command:

  `MEDIATOR_USERNAME=mediator MEDIATOR_PASSWORD=mediator2 MEDIATOR_NEW_USERNAME=mediatoradmin mediator_change_user`

```
 [root@mediator-host ~]# MEDIATOR_USERNAME=mediator
MEDIATOR_PASSWORD='mediator2' MEDIATOR_NEW_USERNAME=mediatoradmin
mediator_change_user
 The account username has been modified successfully.
 [root@mediator-host ~]#
```

Change the password

You can change the password using the following procedure.

About this task

Perform this task on the Linux host where you installed ONTAP Mediator.

If you are unable to reach this command, you might need to run the command using the full path as shown in the following example:

`/usr/local/bin/mediator_change_password`

Steps

Change the password by choosing one of the following options:

- **Option (a)**: Run the `mediator_change_password` command and respond to the prompts as shown in the following example:

```
[root@mediator-host ~]# mediator_change_password
Change the Mediator API password by entering the following values:
   Mediator API User Name: mediatoradmin
             Old Password:
             New Password:
         Confirm Password:
The password has been updated successfully.
[root@mediator-host ~]#
```

- **Option (b)**: Run the following command:

```
MEDIATOR_USERNAME=mediatoradmin MEDIATOR_PASSWORD=mediator1
MEDIATOR_NEW_PASSWORD=mediator2 mediator_change_password
```

The example shows that the password is changed from "mediator1" to "mediator2".

```
 [root@mediator-host ~]# MEDIATOR_USERNAME=mediatoradmin
MEDIATOR_PASSWORD=mediator1 MEDIATOR_NEW_PASSWORD=mediator2
mediator_change_password
 The password has been updated successfully.
 [root@mediator-host ~]#
```

Stop ONTAP Mediator

To stop ONTAP Mediator, perform the following steps:

Steps

1. Stop ONTAP Mediator:

```
systemctl stop ontap_mediator
```

2. Stop SCST:

```
systemctl stop mediator-scst
```

3. Disable ONTAP Mediator and SCST:

```
systemctl diable ontap_mediator mediator-scst
```

Re-enable ONTAP Mediator

To re-enable ONTAP Mediator, perform the following steps:

Steps

1. Enable ONTAP Mediator and SCST:

```
systemctl enable ontap_mediator mediator-scst
```

2. Start SCST:

```
systemctl start mediator-scst
```

3. Start ONTAP Mediator:

```
systemctl start ontap_mediator
```

Verify ONTAP Mediator is healthy

After you install ONTAP Mediator, verify that it is running successfully.

Steps

1. View the status of ONTAP Mediator:

    a. `systemctl status ontap_mediator`

    ```
    [root@scspr1915530002 ~]# systemctl status ontap_mediator

     ontap_mediator.service - ONTAP Mediator
    Loaded: loaded (/etc/systemd/system/ontap_mediator.service; enabled;
    vendor preset: disabled)
    Active: active (running) since Mon 2022-04-18 10:41:49 EDT; 1 weeks 0
    days ago
    Process: 286710 ExecStop=/bin/kill -s INT $MAINPID (code=exited,
    status=0/SUCCESS)
    Main PID: 286712 (uwsgi)
    Status: "uWSGI is ready"
    Tasks: 3 (limit: 49473)
    Memory: 139.2M
    CGroup: /system.slice/ontap_mediator.service
           ├─286712 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
    /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
           ├─286716 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
    /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
           └─286717 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
    /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini

    [root@scspr1915530002 ~]#
    ```

    b. `systemctl status mediator-scst`

```
[root@scspr1915530002 ~]# systemctl status mediator-scst
   Loaded: loaded (/etc/systemd/system/mediator-scst.service;
enabled; vendor preset: disabled)
   Active: active (running) since Mon 2022-04-18 10:41:47 EDT; 1
weeks 0 days ago
  Process: 286595 ExecStart=/etc/init.d/scst start (code=exited,
status=0/SUCCESS)
 Main PID: 286662 (iscsi-scstd)
    Tasks: 1 (limit: 49473)
   Memory: 1.2M
   CGroup: /system.slice/mediator-scst.service
           └─286662 /usr/local/sbin/iscsi-scstd

[root@scspr1915530002 ~]#
```

2. Confirm the ports that are used by ONTAP Mediator:

   `netstat`

```
[root@scspr1905507001 ~]# netstat -anlt | grep -E '3260|31784'

         tcp   0   0 0.0.0.0:31784   0.0.0.0:*      LISTEN

         tcp   0   0 0.0.0.0:3260    0.0.0.0:*      LISTEN

         tcp6  0   0 :::3260         :::*           LISTEN
```

Perform host maintenance

If the VM running ONTAP Mediator needs to be upgraded with a newer kernel, this can cause compatibility issues with the SCST kernel modules used by ONTAP Mediator. In this scenario, NetApp recommends that you manually uninstall and reinstall SCST.

Step 1: Manually uninstall SCST

To uninstall SCST, you need the SCST tar bundle that is used for the installed version of ONTAP Mediator.

Steps

1. Download the appropriate SCST bundle (as shown in the following table) and extract it.

For this version …	Use this tar bundle…
ONTAP Mediator 1.10	scst-3.9.tar.gz
ONTAP Mediator 1.9.1	scst-3.8.0.tar.bz2

ONTAP Mediator 1.9	scst-3.8.0.tar.bz2
ONTAP Mediator 1.8	scst-3.8.0.tar.bz2
ONTAP Mediator 1.7	scst-3.7.0.tar.bz2
ONTAP Mediator 1.6	scst-3.7.0.tar.bz2
ONTAP Mediator 1.5	scst-3.6.0.tar.bz2
ONTAP Mediator 1.4	scst-3.6.0.tar.bz2
ONTAP Mediator 1.3	scst-3.5.0.tar.bz2
ONTAP Mediator 1.1	scst-3.4.0.tar.bz2
ONTAP Mediator 1.0	scst-3.3.0.tar.bz2

   a. Access the open source package from the SCST sourceforge downloads.
   b. Select **Download released versions**.
   c. Extract the bundle to your VM.

2. Run the following uninstall commands in the `scst` directory:
   a. `systemctl stop mediator-scst`
   b. `make scstadm_uninstall`
   c. `make iscsi_uninstall`
   d. `make usr_uninstall`
   e. `make scst_uninstall`
   f. `depmod`

Step 2: Manually install SCST

To manually install SCST, you need the SCST tar bundle that is used for the installed version of ONTAP Mediator (see the SCST table).

> ⓘ Perform this step before you install the ONTAP Mediator. If the SCST version you're using is newer than the version bundled with the ONTAP Mediator installer, the installer skips this step.

1. Run the following install commands in the `scst` directory:
   a. `make 2release`
   b. `make scst_install`
   c. `make usr_install`

d. `make iscsi_install`

e. `make scstadm_install`

f. `depmod`

> If you’re performing a first-time installation and want to pre-install ONTAP Mediator, run the following command before continuing with the next step:
>
> `mkdir -p /opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys`

g. `cp scst/src/certs/scst_module_key.der /opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/`

h. `patch /etc/init.d/scst < /opt/netapp/lib/ontap_mediator/systemd/scst.patch`

> If you’re performing a first-time installation and want to pre-install SCST before installing ONTAP Mediator, you can skip this step. The ONTAP Mediator installer applies any relevant patches to the SCST components during installation.

2. Optionally, if Secure Boot is enabled, before you reboot, perform the following steps:

   a. Determine each file name for the `scst_vdisk`, `scst`, and `iscsi_scst` modules:

```
[root@localhost ~]# modinfo -n scst_vdisk
[root@localhost ~]# modinfo -n scst
[root@localhost ~]# modinfo -n iscsi_scst
```

   b. Determine the kernel release:

```
[root@localhost ~]# uname -r
```

   c. Sign each module file with the kernel:

```
[root@localhost ~]# /usr/src/kernels/<KERNEL-RELEASE>/scripts/sign-
file \sha256 \
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/scst_modu
le_key.priv \
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/scst_modu
le_key.der \
_module-filename_
```

   d. Install the UEFI key with the firmware.

   Instructions for installing the UEFI key are located at:

   `/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/README.module-`

```
signing
```

The generated UEFI key is located at:

```
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/scst_module_key.
der
```

3. Reboot the system:

```
reboot
```

Uninstall ONTAP Mediator

If necessary, you can remove ONTAP Mediator.

Before you begin

You must disconnect ONTAP Mediator from ONTAP before removing it.

About this task

Perform this task on the Linux host where you installed ONTAP Mediator.

If you are unable to reach this command, you might need to run the command using the full path as shown in the following example:

```
/usr/local/bin/uninstall_ontap_mediator
```

Step

1. Uninstall ONTAP Mediator:

```
uninstall_ontap_mediator
```

```
[root@mediator-host ~]# uninstall_ontap_mediator

ONTAP Mediator: Self Extracting Uninstaller

+ Removing ONTAP Mediator. (Log:
/tmp/ontap_mediator.GmRGdA/uninstall_ontap_mediator/remove.log)
+ Remove successful.
[root@mediator-host ~]#
```

Regenerate a temporary self-signed certificate

Beginning with ONTAP Mediator 1.7, you can regenerate a temporary self-signed certificate using the following procedure.

> This procedure is only supported on systems running ONTAP Mediator 1.7 or later.

About this task

- Perform this task on the Linux host where you installed ONTAP Mediator.

* You can perform this task only if the generated self-signed certificates have become obsolete due to changes to the hostname or IP address of the host after installing ONTAP Mediator.
* After the temporary self-signed certificate has been replaced by a trusted third-party certificate, you do *not* use this task to regenerate a certificate. The absence of a self-signed certificate will cause this procedure to fail.

Step

To regenerate a new temporary self-signed certificate for the current host, perform the following step:

1. Restart ONTAP Mediator:

   `./make_self_signed_certs.sh overwrite`

```
[root@xyz000123456 ~]# cd
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config
[root@xyz000123456 server_config]# ./make_self_signed_certs.sh overwrite

Adding Subject Alternative Names to the self-signed server certificate
#
# OpenSSL example configuration file.

...................................................++++
e is 65537 (0x010001)
Generating a RSA private key
............................................++++
....................................................................
.................................................................+++
+
writing new private key to 'ontap_mediator_server.key'
-----
Signature ok
subject=C = US, ST = California, L = San Jose, O = "NetApp, Inc.", OU =
ONTAP Core Software, CN = ONTAP Mediator, emailAddress =
support@netapp.com
Getting CA Private Key
```

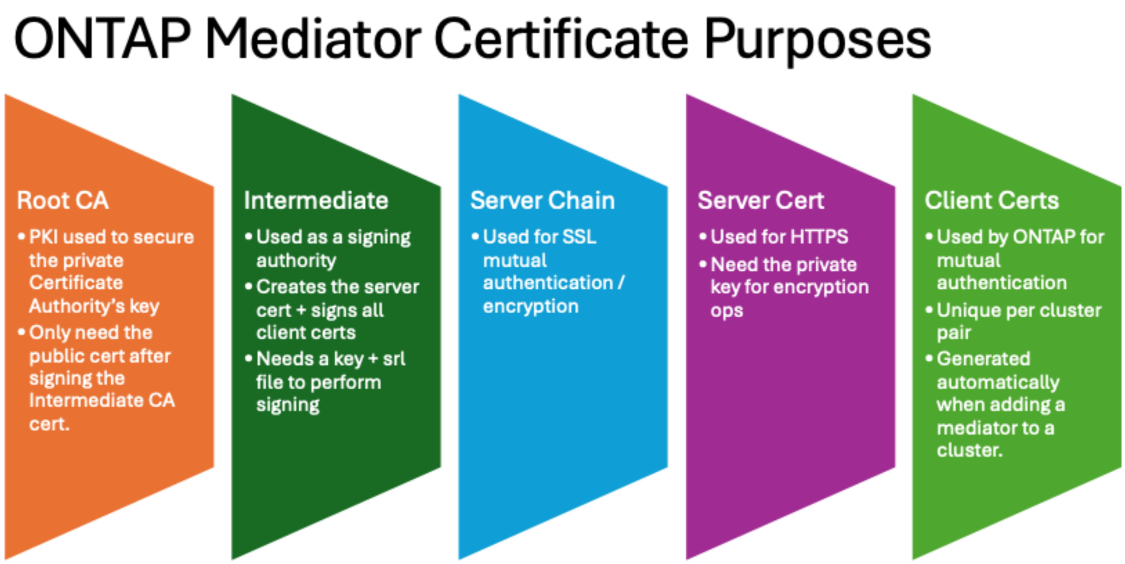
Replace self-signed certificates with trusted third-party certificates

If supported, you can replace self-signed certificates with trusted third-party certificates.

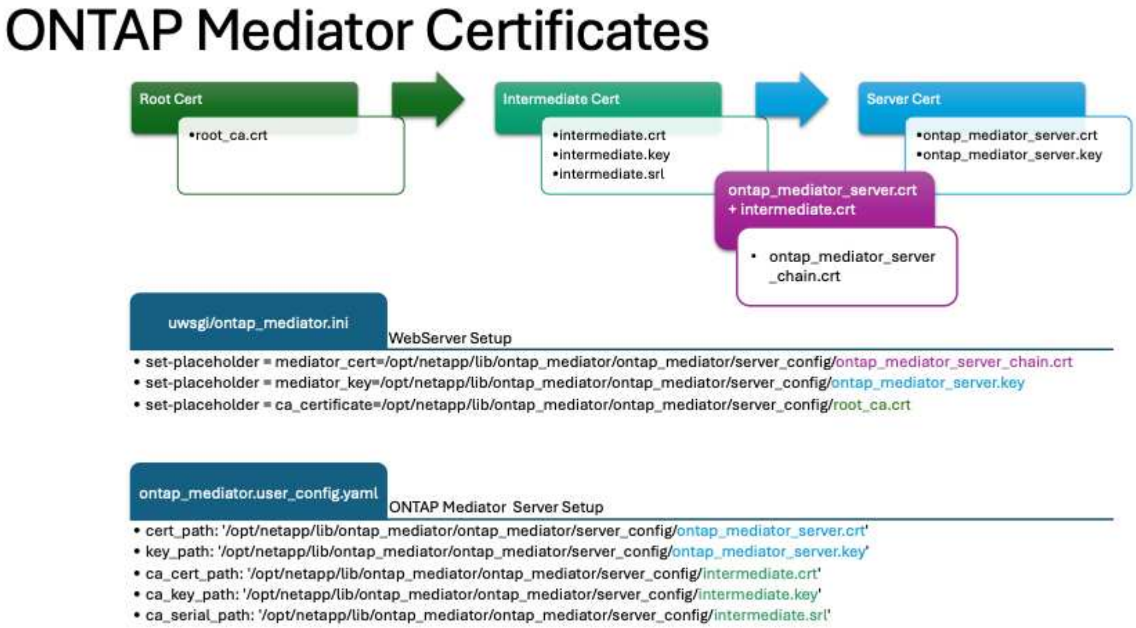
- Third-party certificates are only supported beginning with ONTAP 9.16.1 and in some earlier ONTAP patch releases. See NetApp Bugs Online Bug ID CONTAP-243278.
- Third-party certificates are only supported on systems running ONTAP Mediator 1.7 or later.

About this task

- Perform this task on the Linux host where you installed ONTAP Mediator.
- You can perform this task if the generated self-signed certificates need to be replaced by certificates obtained from a trusted subordinate certificate authority (CA). To accomplish this, you should have access to a trusted public-key infrastructure (PKI) authority.
- The following image shows the purposes of each ONTAP Mediator certificate.



- The following image shows configuration for the web server setup and ONTAP Mediator setup.



Step 1: Obtain a certificate from a third-party issuing a CA certificate

You can obtain a certificate from a PKI authority using the following procedure.

The following example demonstrates replacing the self-signed certificate actors with the third-party certificate actors located at `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/`.

> The example illustrates the necessary criteria for the certificates required for ONTAP Mediator. You can obtain the certificates from a PKI authority in a way that might be different to this procedure. Adjust the procedure according to your business need.

ONTAP Mediator 1.9 and later

1. Create a private key `intermediate.key` and a configuration file `openssl_ca.cnf` that will be consumed by the PKI authority to generate a certificate.
   a. Generate the private key `intermediate.key`:

      Example

      ```
      openssl genrsa -aes256 -out intermediate.key 4096
      ```

   b. The configuration file `openssl_ca.cnf` (located at `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/openssl_ca.cnf`) defines the properties that the generated certificate must have.
2. Use the private key and configuration file to create a certificate signing request `intermediate.csr`:

   Example:

   ```
   openssl req -key <private_key_name>.key -new -out
   <certificate_csr_name>.csr -config <config_file_name>.cnf
   ```

   ```
   [root@scs000216655 server_config]# openssl req -key intermediate.key
   -new -config openssl_ca.cnf -out intermediate.csr
   Enter pass phrase for intermediate.key:
   [root@scs000216655 server_config]# cat intermediate.csr
   -----BEGIN CERTIFICATE REQUEST-----
   <certificate_value>
   -----END CERTIFICATE REQUEST-----
   ```

3. Send the certificate signing request `intermediate.csr` to a PKI authority for their signature.

   The PKI authority verifies the request and signs the `.csr`, generating the certificate `intermediate.crt`. Additionally, you need to obtain the `root_intermediate.crt` certificate that signed the `intermediate.crt` certificate from the PKI authority.

   > For SnapMirror Business Continuity (SM-BC) clusters, you must add the `intermediate.crt` and `root_intermediate.crt` certificates to an ONTAP cluster. See Configure ONTAP Mediator and clusters for SnapMirror active sync.

ONTAP Mediator 1.8 and earlier

1. Create a private key `ca.key` and a configuration file `openssl_ca.cnf` that will be consumed by the PKI authority to generate a certificate.
   a. Generate the private key `ca.key`:

      Example

      ```
      openssl genrsa -aes256 -out ca.key 4096
      ```

b. The configuration file `openssl_ca.cnf` (located at `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/openssl_ca.cnf`) defines the properties that the generated certificate must have.

2. Use the private key and configuration file to create a certificate signing request `ca.csr`:

   Example:

   `openssl req -key <private_key_name>.key -new -out <certificate_csr_name>.csr -config <config_file_name>.cnf`

```
[root@scs000216655 server_config]# openssl req -key ca.key -new
-config openssl_ca.cnf -out ca.csr
Enter pass phrase for ca.key:
[root@scs000216655 server_config]# cat ca.csr
-----BEGIN CERTIFICATE REQUEST-----
<certificate_value>
-----END CERTIFICATE REQUEST-----
```

3. Send the certificate signing request `ca.csr` to a PKI authority for their signature.

   The PKI authority verifies the request and signs the `.csr`, generating the certificate `ca.crt`. Additionally, you need to obtain the `root_ca.crt that signed the `ca.crt` certificate from the PKI authority.

   For SnapMirror Business Continuity (SM-BC) clusters, you must add the `ca.crt` and `root_ca.crt` certificates to an ONTAP cluster. See Configure ONTAP Mediator and clusters for SnapMirror active sync.

Step 2: Generate a server certificate by signing with a third-party CA certification

ONTAP Mediator 1.9 and later

A server certificate must be signed by the private key `intermediate.key` and the third-party certificate `intermediate.crt`. Additionally, the configuration file `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/openssl_server.cnf` contains certain attributes that specify the properties required for server certificates issued by OpenSSL.

The following commands can generate a server certificate.

Steps

1. To generate a server certificate signing request (CSR), run the following command from the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config` folder:

   ```
   openssl req -config openssl_server.cnf -extensions v3_req -nodes -newkey
   rsa:4096 -sha512 -keyout ontap_mediator_server.key -out
   ontap_mediator_server.csr
   ```

2. To generate a server certificate from the CSR, run the following command from the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config` folder:

   > These files were obtained from a PKI authority. If you are using a different certificate name, replace `intermediate.crt` and `intermediate.key` with the relevant file names.

   ```
   openssl x509 -extfile openssl_server.cnf -extensions v3_req -CA
   intermediate.crt -CAkey intermediate.key -CAcreateserial -sha512 -days 1095
   -req -in ontap_mediator_server.csr -out ontap_mediator_server.crt
   ```

   - The `-CAcreateserial` option is used to generate the `intermediate.srl` files.

ONTAP Mediator 1.8 and earlier

A server certificate must be signed by the private key `ca.key` and the third-party certificate `ca.crt`. Additionally, the configuration file `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/openssl_server.cnf` contains certain attributes that specify the properties required for server certificates issued by OpenSSL.

The following commands can generate a server certificate.

Steps

1. To generate a server certificate signing request (CSR), run the following command from the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config` folder:

   ```
   openssl req -config openssl_server.cnf -extensions v3_req -nodes -newkey
   rsa:4096 -sha512 -keyout ontap_mediator_server.key -out
   ontap_mediator_server.csr
   ```

2. To generate a server certificate from the CSR, run the following command from the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config` folder:

   > These files were obtained from a PKI authority. If you are using a different certificate name, replace `ca.crt` and `ca.key` with the relevant file names.

```
openssl x509 -extfile openssl_server.cnf -extensions v3_req -CA ca.crt
-CAkey ca.key -CAcreateserial -sha512 -days 1095 -req -in
ontap_mediator_server.csr -out ontap_mediator_server.crt
```

  - The `-CAcreateserial` option is used to generate the `ca.srl` files.

Step 3: Replace new third-party CA certificate and server certificate in ONTAP Mediator configuration

ONTAP Mediator 1.9 and later

The certificate configuration is supplied to ONTAP Mediator in the configuration file located at `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.config.yaml`. The file includes the following attributes:

```
cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_medi
ator_server.crt'
key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_medi
ator_server.key'
ca_cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/intermedia
te.crt'
ca_key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/intermedia
te.key'
ca_serial_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/intermedia
te.srl'
```

- `cert_path` and `key_path` are server certificate variables.
- `ca_cert_path`, `ca_key_path`, and `ca_serial_path` are CA certificate variables.

Steps

1. Replace all `intermediate.*` files with the third-party certificates.
2. Create a certificate chain from the `intermediate.crt` and `ontap_mediator_server.crt` certificates:

   ```
   cat ontap_mediator_server.crt intermediate.crt >
   ontap_mediator_server_chain.crt
   ```

3. Update the `/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini` file.

   Update the values of `mediator_cert`, `mediator_key`, and `ca_certificate`:

   ```
   set-placeholder = mediator_cert =
   /opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_
   server_chain.crt

   set-placeholder = mediator_key =
   /opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_
   server.key

   set-placeholder = ca_certificate =
   /opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/root_intermedia
   ```

te.crt

- The `mediator_cert` value is the path of the `ontap_mediator_server_chain.crt` file.
- The `mediator_key value` is the key path in the `ontap_mediator_server.crt` file, which is `ontap_mediator_server.key`.
- The `ca_certificate` value is the path of the `root_intermediate.crt` file.

4. Verify that the following attributes of the newly generated certificates are set correctly:
   - Linux Group Owner: `netapp:netapp`
   - Linux permissions: `600`
5. Restart ONTAP Mediator:

   ```
   systemctl restart ontap_mediator
   ```

ONTAP Mediator 1.8 and earlier

The certificate configuration is supplied to ONTAP Mediator in the configuration file located at `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.config.yaml`. The file includes the following attributes:

```
cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_medi
ator_server.crt'
key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_medi
ator_server.key'
ca_cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.crt'
ca_key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.key'
ca_serial_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.srl'
```

- `cert_path` and `key_path` are server certificate variables.
- `ca_cert_path`, `ca_key_path`, and `ca_serial_path` are CA certificate variables.

Steps

1. Replace all `ca.*` files with the third-party certificates.
2. Create a certificate chain from the `ca.crt` and `ontap_mediator_server.crt` certificates:

   ```
   cat ontap_mediator_server.crt ca.crt > ontap_mediator_server_chain.crt
   ```

3. Update the `/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini` file.

   Update the values of `mediator_cert`, `mediator_key`, and `ca_certificate`:

```
set-placeholder = mediator_cert =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_
server_chain.crt

set-placeholder = mediator_key =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_
server.key

set-placeholder = ca_certificate =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/root_ca.crt
```

- The `mediator_cert` value is the path of the `ontap_mediator_server_chain.crt` file.
- The `mediator_key value` is the key path in the `ontap_mediator_server.crt` file, which is `ontap_mediator_server.key`.
- The `ca_certificate` value is the path of the `root_ca.crt` file.

4. Verify that the following attributes of the newly generated certificates are set correctly:
   - Linux Group Owner: `netapp:netapp`
   - Linux permissions: `600`
5. Restart ONTAP Mediator:

```
systemctl restart ontap_mediator
```

Step 4: Optionally, use a different path or name for your third-party certificates

ONTAP Mediator 1.9 and later

You can use third-party certificates with a different name other than `intermediate.*` or store the third-party certificates in a different location.

Steps

1. Configure the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.user_config.yaml` file to override the default variable values in the `ontap_mediator.config.yaml` file.

   If you obtained `intermediate.crt` from a PKI authority and you store its private key `intermediate.key` at the location `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config`, the `ontap_mediator.user_config.yaml` file should look like the following example:

   > If you used `intermediate.crt` to sign the `ontap_mediator_server.crt` certificate, the `intermediate.srl` file is generated. See Step 2: Generate a server certificate by signing with a third-party CA certification for more information.

```
[root@scs000216655 server_config]# cat
ontap_mediator.user_config.yaml

# This config file can be used to override the default settings in
ontap_mediator.config.yaml
# To override a setting, copy the property key from
ontap_mediator.config.yaml to this file and
# set the property to the desired value. e.g.,
#
# The default value for 'default_mailboxes_per_target' is 4 in
ontap_mediator.config.yaml
#
# To override this value with 6 mailboxes per target, add the
following key/value pair
# below this comment:
#
# 'default_mailboxes_per_target': 6
#
cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_m
ediator_server.crt'
key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_m
ediator_server.key'
ca_cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/interme
diate.crt'
ca_key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/interme
diate.key'
ca_serial_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/interme
diate.srl'
```

a. If you are using a certificate structure where the `root_intermediate.crt` certificate provides an `intermediate.crt` certificate that signs the `ontap_mediator_server.crt` certificate, create a certificate chain from the `intermediate.crt` and `ontap_mediator_server.crt` certificates:

> You should have obtained the `intermediate.crt` and `ontap_mediator_server.crt` certificates from a PKI authority earlier in the procedure.

```
cat ontap_mediator_server.crt intermediate.crt >
ontap_mediator_server_chain.crt
```

b. Update the `/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini` file.

Update the values of `mediator_cert`, `mediator_key`, and `ca_certificate`:

```
set-placeholder = mediator_cert =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediat
or_server_chain.crt

set-placeholder = mediator_key =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediat
or_server.key

set-placeholder = ca_certificate =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/root_interme
diate.crt
```

- The `mediator_cert` value is the path of the `ontap_mediator_server_chain.crt` file.
- The `mediator_key` value is the key path in the `ontap_mediator_server.crt` file, which is `ontap_mediator_server.key`.
- The `ca_certificate` value is the path of the `root_intermediate.crt` file.

> For SnapMirror Business Continuity (SM-BC) clusters, you must add the `intermediate.crt` and `root_intermediate.crt` certificates to an ONTAP cluster. See Configure ONTAP Mediator and clusters for SnapMirror active sync.

c. Verify that the following attributes of the newly generated certificates are set correctly:

- Linux Group Owner: `netapp:netapp`
- Linux permissions: `600`

2. Restart ONTAP Mediator when the certificates are updated in the configuration file:

```
systemctl restart ontap_mediator
```

ONTAP Mediator 1.8 and earlier

You can use third-party certificates with a different name other than `ca.*` or store the third-party certificates in a different location.

Steps

1. Configure the `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator.user_config.yaml` file to override the default variable values in the `ontap_mediator.config.yaml` file.

If you obtained `ca.crt` from a PKI authority and you store its private key `ca.key` at the location `/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config`, the `ontap_mediator.user_config.yaml` file should look like the following example:

If you used `ca.crt` to sign the `ontap_mediator_server.crt` certificate, the `ca.srl` file is generated. See Step 2: Generate a server certificate by signing with a third-party CA certification for more information.

```
[root@scs000216655 server_config]# cat
ontap_mediator.user_config.yaml

# This config file can be used to override the default settings in
ontap_mediator.config.yaml
# To override a setting, copy the property key from
ontap_mediator.config.yaml to this file and
# set the property to the desired value. e.g.,
#
# The default value for 'default_mailboxes_per_target' is 4 in
ontap_mediator.config.yaml
#
# To override this value with 6 mailboxes per target, add the
following key/value pair
# below this comment:
#
# 'default_mailboxes_per_target': 6
#
cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_m
ediator_server.crt'
key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_m
ediator_server.key'
ca_cert_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.crt'
ca_key_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.key'
ca_serial_path:
'/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.srl'
```

a. If you are using a certificate structure where the `root_ca.crt` certificate provides an `ca.crt` certificate that signs the `ontap_mediator_server.crt` certificate, create a certificate chain from the `ca.crt` and `ontap_mediator_server.crt` certificates:

   You should have obtained the `ca.crt` and `ontap_mediator_server.crt` certificates from a PKI authority earlier in the procedure.

   ```
   cat ontap_mediator_server.crt ca.crt > ontap_mediator_server_chain.crt
   ```

b. Update the `/opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini` file.

Update the values of `mediator_cert`, `mediator_key`, and `ca_certificate`:

```
set-placeholder = mediator_cert =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediat
or_server_chain.crt

set-placeholder = mediator_key =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediat
or_server.key

set-placeholder = ca_certificate =
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/root_ca.crt
```

- The `mediator_cert` value is the path of the `ontap_mediator_server_chain.crt` file.
- The `mediator_key` value is the key path in the `ontap_mediator_server.crt` file, which is `ontap_mediator_server.key`.
- The `ca_certificate` value is the path of the `root_ca.crt` file.

> For SnapMirror Business Continuity (SM-BC) clusters, you must add the `ca.crt` and `root_ca.crt` certificates to an ONTAP cluster. See Configure ONTAP Mediator and clusters for SnapMirror active sync.

c. Verify that the following attributes of the newly generated certificates are set correctly:

- Linux Group Owner: `netapp:netapp`
- Linux permissions: `600`

2. Restart ONTAP Mediator when the certificates are updated in the configuration file:

```
systemctl restart ontap_mediator
```

Troubleshoot certificate-related issues

You can check certain properties of the certificates.

Verify certificate expiration

Use the following command to identify the certificate validity range.

ONTAP Mediator 1.9 and later

```
[root@mediator_host server_config]# openssl x509 -in intermediate.crt
-text -noout
Certificate:
    Data:
...
        Validity
            Not Before: Feb 22 19:57:25 2024 GMT
            Not After : Feb 15 19:57:25 2029 GMT
```

ONTAP Mediator 1.8 and earlier

```
[root@mediator_host server_config]# openssl x509 -in ca.crt -text
-noout
Certificate:
    Data:
...
        Validity
            Not Before: Feb 22 19:57:25 2024 GMT
            Not After : Feb 15 19:57:25 2029 GMT
```

Verify X509v3 extensions in CA certification

Use the following command to verify the X509v3 extensions in the CA certification.

ONTAP Mediator 1.9 and later

The properties defined within **v3_ca** in `openssl_ca.cnf` are displayed as `X509v3 extensions` in `intermediate.crt`.

```
[root@mediator_host server_config]# pwd
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config

[root@mediator_host server_config]# cat openssl_ca.cnf
...
[ v3_ca ]
subjectKeyIdentifier = hash
authorityKeyIdentifier = keyid:always,issuer
basicConstraints = critical, CA:true
keyUsage = critical, cRLSign, digitalSignature, keyCertSign

[root@mediator_host server_config]# openssl x509 -in intermediate.crt
-text -noout
Certificate:
    Data:
...
        X509v3 extensions:
            X509v3 Subject Key Identifier:

9F:06:FA:47:00:67:BA:B2:D4:82:70:38:B8:48:55:B5:24:DB:FC:27
            X509v3 Authority Key Identifier:

keyid:9F:06:FA:47:00:67:BA:B2:D4:82:70:38:B8:48:55:B5:24:DB:FC:27

            X509v3 Basic Constraints: critical
                CA:TRUE
            X509v3 Key Usage: critical
                Digital Signature, Certificate Sign, CRL Sign
```

ONTAP Mediator 1.8 and earlier

The properties defined within **v3_ca** in `openssl_ca.cnf` are displayed as `X509v3 extensions` in `ca.crt`.

```
[root@mediator_host server_config]# pwd
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config

[root@mediator_host server_config]# cat openssl_ca.cnf
...
[ v3_ca ]
subjectKeyIdentifier = hash
authorityKeyIdentifier = keyid:always,issuer
basicConstraints = critical, CA:true
keyUsage = critical, cRLSign, digitalSignature, keyCertSign

[root@mediator_host server_config]# openssl x509 -in ca.crt -text
-noout
Certificate:
    Data:
...
        X509v3 extensions:
            X509v3 Subject Key Identifier:

9F:06:FA:47:00:67:BA:B2:D4:82:70:38:B8:48:55:B5:24:DB:FC:27
            X509v3 Authority Key Identifier:

keyid:9F:06:FA:47:00:67:BA:B2:D4:82:70:38:B8:48:55:B5:24:DB:FC:27

            X509v3 Basic Constraints: critical
                CA:TRUE
            X509v3 Key Usage: critical
                Digital Signature, Certificate Sign, CRL Sign
```

Verify X509v3 extensions in server certificate and subject Alt Names

The `v3_req` properties defined in the `openssl_server.cnf` configuration file are displayed as `X509v3 extensions` in the certificate.

In the following example, you can obtain the variables in the `alt_names` sections by running the commands `hostname -A` and `hostname -I` on the Linux VM on which ONTAP Mediator is installed.

Check with your network administrator for the correct values of the variables.

ONTAP Mediator 1.9 and later

```
[root@mediator_host server_config]# pwd
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config

[root@mediator_host server_config]# cat openssl_server.cnf
...
[ v3_req ]
basicConstraints       = CA:false
extendedKeyUsage       = serverAuth
keyUsage               = keyEncipherment, dataEncipherment
subjectAltName         = @alt_names

[ alt_names ]
DNS.1 = abc.company.com
DNS.2 = abc-v6.company.com
IP.1 = 1.2.3.4
IP.2 = abcd:abcd:abcd:abcd:abcd:abcd

[root@mediator_host server_config]# openssl x509 -in intermediate.crt

```

Verify that a private key matches with a certificate

You can verify whether a particular private key matches with a certificate.

Use the following OpenSSL commands on the key and certificate respectively.

ONTAP Mediator 1.9 and later

```
[root@mediator_host server_config]# openssl rsa -noout -modulus -in
intermediate.key | openssl md5
Enter pass phrase for intermediate.key:
(stdin)= 14c6b98b0c7c59012b1de89eee4a9dbc
[root@mediator_host server_config]# openssl x509 -noout -modulus -in
intermediate.crt | openssl md5
(stdin)= 14c6b98b0c7c59012b1de89eee4a9dbc
```

ONTAP Mediator 1.8 and earlier

```
[root@mediator_host server_config]# openssl rsa -noout -modulus -in
ca.key | openssl md5
Enter pass phrase for ca.key:
(stdin)= 14c6b98b0c7c59012b1de89eee4a9dbc
[root@mediator_host server_config]# openssl x509 -noout -modulus -in
ca.crt | openssl md5
(stdin)= 14c6b98b0c7c59012b1de89eee4a9dbc
```

If the `-modulus` attribute for both match, it indicates that the private key and certificate pair are compatible and can work with each other.

Verify that a server certificate is created from a particular CA certificate

You can use the following command to verify that the server certificate is created from a particular CA certificate.

ONTAP Mediator 1.9 and later

```
[root@mediator_host server_config]# openssl verify -CAfile root_ca.crt
--untrusted intermediate.crt ontap_mediator_server.crt
ontap_mediator_server.crt: OK
[root@mediator_host server_config]#
```

ONTAP Mediator 1.8 and earlier

```
[root@mediator_host server_config]# openssl verify -CAfile ca.crt
ontap_mediator_server.crt
ontap_mediator_server.crt: OK
```

If the Online Certificate Status Protocol (OCSP) validation is being used, use the command openssl-verify.

Maintain the host OS for ONTAP Mediator

For optimal performance, you should maintain the host OS for ONTAP Mediator on a regular basis.

Reboot the host

Reboot the host when the clusters are healthy. While ONTAP Mediator is offline, the clusters are at risk of not being able to react properly to failures. A service window is recommended if a reboot is required.

ONTAP Mediator will automatically resume during a reboot and will re-enter the relationships that were previously configured with ONTAP clusters.

Host package updates

Any library or yum packages (except the kernel) can be safely updated but might require a reboot to take effect. A service window is recommended if a reboot is required.

If you install the `yum-utils` package, use the `needs-restarting` command to detect if any package changes require a reboot.

You should reboot if any of the ONTAP Mediator dependencies are updated because they will not take immediate effect on running processes.

Host OS minor kernel upgrades

SCST must be compiled for the kernel that is being used. To update the OS, a maintenance window is required.

Steps

Perform the following steps to upgrade the host OS kernel.

1. Stop ONTAP Mediator.
2. Uninstall the SCST package. (SCST doesn’t provide an upgrade mechanism.)
3. Upgrade the OS, and reboot.
4. Re-install the SCST package.
5. Re-enable ONTAP Mediator.

Host changes to the hostname or IP

About this task

- Perform this task on the Linux host where you installed ONTAP Mediator.
- You can perform this task only if the generated self-signed certificates have become obsolete due to changes to the hostname or IP address of the host after installing ONTAP Mediator.
- After the temporary self-signed certificate has been replaced by a trusted third-party certificate, you do *not* use this task to regenerate a certificate. The absence of a self-signed certificate will cause this procedure to fail.

Step

To regenerate a new temporary self-signed certificate for the current host, perform the following step:

1. Restart ONTAP Mediator:

   `./make_self_signed_certs.sh overwrite`

```
[root@xyz000123456 ~]# cd
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config
[root@xyz000123456 server_config]# ./make_self_signed_certs.sh overwrite

Learn about MetroCluster IP site management with ONTAP System Manager

MetroCluster configurations synchronously mirror data and configuration between two ONTAP clusters in separate locations. Beginning with ONTAP 9.8, you can use System Manager as a simplified interface for managing a MetroCluster IP configuration.

> ⓘ You can only perform MetroCluster operations using System Manager in a MetroCluster IP configuration. In a MetroCluster FC configuration, you can still use System Manager to manage each node in your MetroCluster configuration, but you can't perform any MetroCluster-specific operations.

Typically, you set up and configure clusters in a MetroCluster configuration in two separate geographical sites. You then set up peering between the clusters so that they synchronize and share data. The two clusters in the peered network provide bidirectional disaster recovery (DR), where each cluster can be the source and backup of the other cluster. In eight-node or four-node MetroCluster IP configurations, each site consists of storage controllers configured as one or two high availability (HA) pairs.

You can install ONTAP Mediator in a third location to monitor the state of the nodes and their DR partners. ONTAP Mediator can implement a Mediator-assisted unplanned switchover (MAUSO) in the case of a disaster.

You can also perform a negotiated switchover to bring down one of the clusters for planned maintenance. The partner cluster handles all data I/O operations for both clusters until you bring up the cluster that you performed maintenance on and perform a switchback operation.

You can find procedures for setting up and managing a MetroCluster IP configuration using System Manager in the MetroCluster documentation.

Data protection using tape backup

Learn about tape backup of FlexVol volumes with ONTAP

ONTAP supports tape backup and restore through Network Data Management Protocol (NDMP). NDMP allows you to back up data in storage systems directly to tape, resulting in efficient use of network bandwidth. ONTAP supports both dump and SMTape engines for tape backup.

You can perform a dump or SMTape backup or restore by using NDMP-compliant backup applications. Only NDMP version 4 is supported.

Tape backup using dump

Dump is a snapshot-based backup in which your file system data is backed up to tape. The ONTAP dump engine backs up files, directories, and the applicable access control list (ACL) information to tape. You can back up an entire volume, an entire qtree, or a subtree that is not an entire volume or an entire qtree. Dump supports baseline, differential, and incremental backups.

Tape backup using SMTape

SMTape is a snapshot-based disaster recovery solution from ONTAP that backs up blocks of data to tape. You can use SMTape to perform volume backups to tapes. However, you cannot perform a backup at the qtree or subtree level. SMTape supports baseline, differential, and incremental backups.

Beginning with ONTAP 9.13.1, Tape backup using SMTape is supporting with SnapMirror active sync.

Tape backup and restore workflow in ONTAP

You can perform tape backup and restore operations by using an NDMP-enabled backup application.

About this task

The tape backup and restore workflow provides an overview of the tasks that are involved in performing tape backup and restore operations. For detailed information about performing a backup and restore operation, see the backup application documentation.

Steps

1. Set up a tape library configuration by choosing an NDMP-supported tape topology.
2. Enable NDMP services on your storage system.

   You can enable the NDMP services either at the node level or at the storage virtual machine (SVM) level. This depends on the NDMP mode in which you choose to perform the tape backup and restore operation.

3. Use NDMP options to manage NDMP on your storage system.

   You can use NDMP options either at the node level or at the SVM level. This depends on the NDMP mode in which you choose to perform the tape backup and restore operation.

   You can modify the NDMP options at the node level by using the `system services ndmp modify` command and at the SVM level by using the `vserver services ndmp modify` command. Learn more about `system services ndmp modify` and `vserver services ndmp modify` in the ONTAP command reference.

4. Perform a tape backup or restore operation by using an NDMP-enabled backup application.

   ONTAP supports both dump and SMTape engines for tape backup and restore.

   For more information about using the backup application (also called *Data Management Applications* or *DMAs*) to perform backup or restore operations, see your backup application documentation.

Related information

Common NDMP tape backup topologies

Understanding dump engine for FlexVol volumes

Use cases for choosing a tape backup engine

ONTAP supports two backup engines: SMTape and dump. You should be aware of the use cases for the SMTape and dump backup engines to help you choose the backup engine to perform tape backup and restore operations.

Dump can be used in the following cases:

- Direct Access Recovery (DAR) of files and directories
- Backup of a subset of subdirectories or files in a specific path
- Excluding specific files and directories during backups
- Preserving backup for long durations

SMTape can be used in the following cases:

- Disaster recovery solution
- Preserving deduplication savings and deduplication settings on the backed up data during a restore operation
- Backup of large volumes

Manage tape drives

Manage tape drives overview

You can verify tape library connections and view tape drive information before performing a tape backup or restore operation. You can use a nonqualified tape drive by emulating this to a qualified tape drive. You can also assign and remove tape aliases in addition to viewing existing aliases.

When you back up data to tape, the data is stored in tape files. File marks separate the tape files, and the files have no names. You specify a tape file by its position on the tape. You write a tape file by using a tape device. When you read the tape file, you must specify a device that has the same compression type that you used to write that tape file.

Commands for managing tape drives, media changers, and tape drive operations in ONTAP

There are commands for viewing information about tape drives and media changers in a cluster, bringing a tape drive online and taking it offline, modifying the tape drive cartridge position, setting and clearing tape drive alias name, and resetting a tape drive. You can also view and reset tape drive statistics.

If you want to…	Use this command…
Bring a tape drive online	`storage tape online`
Clear an alias name for tape drive or media changer	`storage tape alias clear`
Enable or disable a tape trace operation for a tape drive	`storage tape trace`
Modify the tape drive cartridge position	`storage tape position`
Reset a tape drive	`storage tape reset` ⓘ This command is available only at the advanced privilege level.
Set an alias name for tape drive or media changer	`storage tape alias set`
Take a tape drive offline	`storage tape offline`
View information about all tape drives and media changers	`storage tape show`
View information about tape drives attached to the cluster	• `storage tape show-tape-drive` • `system node hardware tape drive show`

If you want to…	Use this command…
View information about media changers attached to the cluster	`storage tape show-media-changer`
View error information about tape drives attached to the cluster	`storage tape show-errors`
View all ONTAP qualified and supported tape drives attached to each node in the cluster	`storage tape show-supported-status`
View aliases of all tape drives and media changers attached to each node in the cluster	`storage tape alias show`
Reset the statistics reading of a tape drive to zero	`storage stats tape zero` `tape_name` You must use this command at the nodeshell.
View tape drives supported by ONTAP	`storage show tape supported [-v]` You must use this command at the nodeshell. You can use the `-v` option to view more details about each tape drive.
View tape device statistics to understand tape performance and check usage pattern	`storage stats tape` `tape_name` You must use this command at the nodeshell.

Learn more about `storage tape` in the ONTAP command reference.

Use a nonqualified tape drive

You can use a nonqualified tape drive on a storage system if it can emulate a qualified tape drive. It is then treated like a qualified tape drive. To use a nonqualified tape drive, you must first determine whether it emulates any of the qualified tape drives.

About this task

A nonqualified tape drive is one that is attached to the storage system, but not supported or recognized by ONTAP.

Steps

1. View the nonqualified tape drives attached to a storage system by using the `storage tape show-supported-status` command.

   The following command displays tape drives attached to the storage system and the support and qualification status of each tape drive. The nonqualified tape drives are also listed. `tape_drive_vendor_name` is a nonqualified tape drive attached to the storage system, but not supported by ONTAP.

```
cluster1::> storage tape show-supported-status -node Node1

          Node: Node1
                                     Is
          Tape Drive                 Supported  Support Status
          --------------------       ---------  --------------
          "tape_drive_vendor_name"   false      Nonqualified tape drive
          Hewlett-Packard C1533A     true       Qualified
          Hewlett-Packard C1553A     true       Qualified
          Hewlett-Packard Ultrium 1 true       Qualified
          Sony SDX-300C              true       Qualified
          Sony SDX-500C              true       Qualified
          StorageTek T9840C          true       Dynamically Qualified
          StorageTek T9840D          true       Dynamically Qualified
          Tandberg LTO-2 HH          true       Dynamically Qualified
```

2. Emulate the qualified tape drive.

   NetApp Downloads: Tape Device Configuration Files

Related information

What qualified tape drives are

Assign tape aliases in ONTAP

For easy device identification, you can assign tape aliases to a tape drive or medium changer. Aliases provide a correspondence between the logical names of backup devices and a name permanently assigned to the tape drive or medium changer.

Steps

1. Assign an alias to a tape drive or medium changer by using the `storage tape alias set` command.

   Learn more about `storage tape alias set` in the ONTAP command reference.

   You can view the serial number (SN) information about the tape drives by using the `system node hardware tape drive show` command and about tape libraries by using the `system node hardware tape library show` commands.

   The following command sets an alias name to a tape drive with serial number SN[123456]L4 attached to the node, cluster1-01:

```
cluster-01::> storage tape alias set  -node cluster-01 -name st3
-mapping SN[123456]L4
```

   The following command sets an alias name to a media changer with serial number SN[65432] attached to the node, cluster1-01:

```
cluster-01::> storage tape alias set  -node cluster-01 -name mc1
-mapping SN[65432]
```

Related information

What tape aliasing is

Removing tape aliases

Remove tape aliases in ONTAP

You can remove aliases by using the `storage tape alias clear` command when persistent aliases are no longer required for a tape drive or medium changer.

Steps

1. Remove an alias from a tape drive or medium changer by using the `storage tape alias clear` command.

   Learn more about `storage tape alias clear` in the ONTAP command reference.

   The following command removes the aliases of all tape drives by specifying the scope of the alias clear operation to `tape`:

   ```
   cluster-01::>storage tape alias clear -node cluster-01 -clear-scope tape
   ```

After you finish

If you are performing a tape backup or restore operation using NDMP, then after you remove an alias from a tape drive or medium changer, you must assign a new alias name to the tape drive or medium changer to continue access to the tape device.

Related information

What tape aliasing is

Assigning tape aliases

Enabling or disabling tape reservations

You can control how ONTAP manages tape device reservations by using the `tape.reservations` option. By default, tape reservation is turned off.

About this task

Enabling the tape reservations option can cause problems if tape drives, medium changers, bridges, or libraries do not work properly. If tape commands report that the device is reserved when no other storage systems are using the device, this option should be disabled.

Steps

1. To use either the SCSI Reserve/Release mechanism or SCSI Persistent Reservationsor to disable tape reservations, enter the following commandat the clustershell:

options -option-name tape.reservations -option-value {scsi | persistent | off}

`scsi` selects the SCSI Reserve/Release mechanism.

`persistent` selects SCSI Persistent Reservations.

`off` disables tape reservations.

Related information

What tape reservations are

Commands for verifying tape library connections in ONTAP

You can view information about the connection path between a storage system and a tape library configuration attached to the storage system. You can use this information to verify the connection path to the tape library configuration or for troubleshooting issues related to the connection paths.

You can view the following tape library details to verify the tape library connections after adding or creating a new tape library, or after restoring a failed path in a single-path or multipath access to a tape library. You can also use this information while troubleshooting path-related errors or if access to a tape library fails.

- Node to which the tape library is attached
- Device ID
- NDMP path
- Tape library name
- Target port and initiator port IDs
- Single-path or multipath access to a tape library for every target or FC initiator port
- Path-related data integrity details, such as “Path Errors” and “Path Qual”
- LUN groups and LUN counts

If you want to…	Use this command…
View information about a tape library in a cluster	`system node hardware tape library show`
View path information for a tape library	`storage tape library path show`
View path information for a tape library for every initiator port	`storage tape library path show-by-initiator`
View connectivity information between a storage tape library and cluster	`storage tape library config show`

Learn more about `storage tape library` in the ONTAP command reference.

About tape drives

Qualified tape drives overview

You must use a qualified tape drive that has been tested and found to work properly on a storage system. You can follow tape aliasing and also enable tape reservations to ensure that only one storage system accesses a tape drive at any particular time.

A qualified tape drive is a tape drive that has been tested and found to work properly on storage systems. You can qualify tape drives for existing ONTAP releases by using the tape configuration file.

Format of the tape configuration file

The tape configuration file format consists of fields such as vendor ID, product ID, and details of compression types for a tape drive. This file also consists of optional fields for enabling the autoload feature of a tape drive and changing the command timeout values of a tape drive.

The following table displays the format of the tape configuration file:

Item	Size	Description
`vendor_id` (string)	up to 8 bytes	The vendor ID as reported by the `SCSI Inquiry` command.
`product_id`(string)	up to 16 bytes	The product ID as reported by the `SCSI Inquiry` command.
`id_match_size`(number)		The number of bytes of the product ID to be used for matching to detect the tape drive to be identified, beginning with the first character of the product ID in the Inquiry data.
`vendor_pretty` (string)	up to 16 bytes	If this parameter is present, it is specified by the string displayed by the command, `storage tape show -device-names`; otherwise, INQ_VENDOR_ID is displayed.
`product_pretty`(string)	up to 16 bytes	If this parameter is present, it is specified by the string displayed by the command, `storage tape show -device-names`; otherwise, INQ_PRODUCT_ID is displayed.

> The `vendor_pretty` and `product_pretty` fields are optional, but if one of these fields has a value, the other must also have a value.

The following table explains the description, density code, and compression algorithm for the various compression types, such as `l`, `m`, `h`, and `a`:

Item	Size	Description
`{l | m | h | a}_description=(string)`	up to 24 bytes	The string to print for the nodeshell command, `sysconfig -t`, that describes characteristics of the particular density setting.
`{l | m | h | a}_density=(hex codes)`		The density code to be set in the SCSI mode page block descriptor corresponding to the desired density code for l, m, h, or a.
`{l | m | h | a}_algorithm=(hex codes)`		The compression algorithm to be set in the SCSI Compression Mode Page corresponding to the density code and the desired density characteristic.

The following table describes the optional fields available in the tape configuration file:

Field	Description
`autoload=(Boolean yes/no)`	This field is set to `yes` if the tape drive has an automatic loading feature; that is, after tape cartridge is inserted, the tape drive becomes ready without the need to execute a `SCSI load` (start/stop unit) command. The default for this field is `no`.
`cmd_timeout_0x`	Individual timeout value. You must use this field only if you want to specify a different timeout value from the one being used as a default by the tape driver. The sample file lists the default SCSI command timeout values used by the tape drive. The timeout value can be expressed in minutes (m), seconds (s), or milliseconds (ms). You should not change this field.

You can download and view the tape configuration file from the NetApp Support Site.

Example of a tape configuration file format

The tape configuration file format for the HP LTO5 ULTRIUM tape drive is as follows:

`vendor_id`="HP"

`product_id`="Ultrium 5-SCSI"

`id_match_size`=9

`vendor_pretty`="Hewlett-Packard"

`product_pretty`="LTO-5"

`l_description`="LTO-3(ro)/4 4/800GB"

`l_density`=0x00

`l_algorithm`=0x00

`m_description`="LTO-3(ro)/4 8/1600GB cmp"

`m_density`=0x00

`m_algorithm`=0x01

`h_description`="LTO-5 1600GB"

`h_density`=0x58

`h_algorithm`=0x00

`a_description`="LTO-5 3200GB cmp"

`a_density`=0x58

`a_algorithm`=0x01

`autoload`="yes"

NetApp Tools: Tape Device Configuration Files

How the storage system qualifies a new tape drive dynamically

The storage system qualifies a tape drive dynamically by matching its vendor ID and product ID with the information contained in the tape qualification table.

When you connect a tape drive to the storage system, it looks for a vendor ID and product ID match between the information obtained during tape discovery and the information in the internal tape qualification table. If the storage system discovers a match, it marks the tape drive as qualified and can access the tape drive. If the storage system cannot find a match, the tape drive remains in the unqualified state and is not accessed.

Tape devices overview

Tape devices overview

A tape device is a representation of a tape drive. It is a specific combination of rewind type and compression capability of a tape drive.

A tape device is created for each combination of rewind type and compression capability. Therefore, a tape drive or tape library can have several tape devices associated with it. You must specify a tape device to move, write, or read tapes.

When you install a tape drive or tape library on a storage system, ONTAP creates tape devices associated with the tape drive or tape library.

ONTAP detects tape drives and tape libraries and assigns logical numbers and tape devices to them. ONTAP detects the Fibre Channel, SAS, and parallel SCSI tape drives and libraries when they are connected to the interface ports. ONTAP detects these drives when their interfaces are enabled.

Tape device name format

Each tape device has an associated name that appears in a defined format. The format includes information about the type of device, rewind type, alias, and compression type.

The format of a tape device name is as follows:

`rewind_type` `st` `alias_number` `compression_type`

`rewind_type` is the rewind type.

The following list describes the various rewind type values:

- **r**

  ONTAP rewinds the tape after it finishes writing the tape file.

- **nr**

  ONTAP does not rewind the tape after it finishes writing the tape file. You must use this rewind type when you want to write multiple tape files on the same tape.

- **ur**

  This is the unload/reload rewind type. When you use this rewind type, the tape library unloads the tape when it reaches the end of a tape file, and then loads the next tape, if there is one.

  You must use this rewind type only under the following circumstances:

  - The tape drive associated with this device is in a tape library or is in a medium changer that is in the library mode.
  - The tape drive associated with this device is attached to a storage system.
  - Sufficient tapes for the operation that you are performing are available in the library tape sequence defined for this tape drive.

> If you record a tape using a no-rewind device, you must rewind the tape before you read it.

`st` is the standard designation for a tape drive.

`alias_number` is the alias that ONTAP assigns to the tape drive. When ONTAP detects a new tape drive, ONTAP assigns an alias to the tape drive.

`compression_type` is a drive-specific code for the density of data on the tape and the type of compression.

The following list describes the various values for `compression_type`:

- **a**

  Highest compression

- **h**

  High compression

- **m**

  Medium compression

- **l**

  Low compression

Examples

`nrst0a` specifies a no-rewind device on tape drive 0 using the highest compression.

Example of a listing of tape devices

The following example shows the tape devices associated with HP Ultrium 2-SCSI:

```
         Tape drive (fc202_6:2.126L1)  HP      Ultrium 2-SCSI
  rst0l  -  rewind device,        format is: HP (200GB)
  nrst0l -  no rewind device,     format is: HP (200GB)
  urst0l -  unload/reload device, format is: HP (200GB)
  rst0m  -  rewind device,        format is: HP (200GB)
  nrst0m -  no rewind device,     format is: HP (200GB)
  urst0m -  unload/reload device, format is: HP (200GB)
  rst0h  -  rewind device,        format is: HP (200GB)
  nrst0h -  no rewind device,     format is: HP (200GB)
  urst0h -  unload/reload device, format is: HP (200GB)
  rst0a  -  rewind device,        format is: HP (400GB w/comp)
  nrst0a -  no rewind device,     format is: HP (400GB w/comp)
  urst0a -  unload/reload device, format is: HP (400GB w/comp)
```

The following list describes the abbreviations in the preceding example:

- GB—Gigabytes; this is the capacity of the tape.
- w/comp—With compression; this shows the tape capacity with compression.

Supported number of simultaneous tape devices

ONTAP supports a maximum of 64 simultaneous tape drive connections, 16 medium changers, and 16 bridge or router devices for each storage system (per node) in any mix of Fibre Channel, SCSI, or SAS attachments.

Tape drives or medium changers can be devices in physical or virtual tape libraries or stand-alone devices.

> Although a storage system can detect 64 tape drive connections, the maximum number of backup and restore sessions that can be performed simultaneously depends upon the scalability limits of the backup engine.

Scalability limits for dump backup and restore sessions

Tape aliasing

Tape aliasing overview

Aliasing simplifies the process of device identification. Aliasing binds a physical path name (PPN) or a serial number (SN) of a tape or a medium changer to a persistent, but modifiable alias name.

The following table describes how tape aliasing enables you to ensure that a tape drive (or tape library or medium changer) is always associated with a single alias name:

Scenario	Reassigning of the alias
When the system reboots	The tape drive is automatically reassigned its previous alias.
When a tape device moves to another port	The alias can be adjusted to point to the new address.
When more than one system uses a particular tape device	The user can set the alias to be the same for all the systems.

> When you upgrade from Data ONTAP 8.1.x to Data ONTAP 8.2.x, the tape alias feature of Data ONTAP 8.2.x modifies the existing tape alias names. In such a case you might have to update the tape alias names in the backup application.

Assigning tape aliases provides a correspondence between the logical names of backup devices (for example, st0 or mc1) and a name permanently assigned to a port, a tape drive, or a medium changer.

> st0 and st00 are different logical names.

> Logical names and serial numbers are used only to access a device. After the device is accessed, it returns all error messages by using the physical path name.

There are two types of names available for aliasing: physical path name and serial number.

What physical path names are

Physical path names (PPNs) are the numerical address sequences that ONTAP assigns to tape drives and tape libraries based on the SCSI-2/3 adapter or switch (specific location) they are connected to the storage system. PPNs are also known as electrical names.

PPNs of direct-attached devices use the following format: `host_adapter. device_id_lun`

> The LUN value is displayed only for tape and medium changer devices whose LUN values are not zero; that is, if the LUN value is zero the `lun` part of the PPN is not displayed.

For example, the PPN 8.6 indicates that the host adapter number is 8, the device ID is 6, and the logical unit number (LUN) is 0.

SAS tape devices are also direct-attached devices. For example, the PPN 5c.4 indicates that in a storage system, the SAS HBA is connected in slot 5, SAS tape is connected to port C of the SAS HBA, and the device ID is 4.

PPNs of Fibre Channel switch-attached devices use the following format: `switch:port_id. device_id_lun`

For example, the PPN MY_SWITCH:5.3L2 indicates that the tape drive connected to port 5 of a switch called MY_SWITCH is set with device ID 3 and has the LUN 2.

The LUN (logical unit number) is determined by the drive. Fibre Channel, SCSI tape drives and libraries, and disks have PPNs.

PPNs of tape drives and libraries do not change unless the name of the switch changes, the tape drive or library moves, or the tape drive or library is reconfigured. PPNs remain unchanged after reboot. For example, if a tape drive named MY_SWITCH:5.3L2 is removed and a new tape drive with the same device ID and LUN is connected to port 5 of the switch MY_SWITCH, the new tape drive would be accessible by using MY_SWITCH:5.3L2.

What serial numbers are

A serial number (SN) is a unique identifier for a tape drive or a medium changer. ONTAP generates aliases based on SN instead of the WWN.

Since the SN is a unique identifier for a tape drive or a medium changer, the alias remains the same regardless of the multiple connection paths to the tape drive or medium changer. This helps storage systems to track the same tape drive or medium changer in a tape library configuration.

The SN of a tape drive or a medium changer does not change even if you rename the Fibre Channel switch to which the tape drive or medium changer is connected. However, in a tape library if you replace an existing tape drive with a new one, then ONTAP generates new aliases because the SN of the tape drive changes. Also, if you move an existing tape drive to a new slot in a tape library or remap the tape drive's LUN, ONTAP generates a new alias for that tape drive.

> You must update the backup applications with the newly generated aliases.

The SN of a tape device uses the following format: `SN[xxxxxxxxxx]L[X]` `x` is an alphanumeric character and `Lx` is the LUN of the tape device. If the LUN is 0, the `Lx` part of the string is not displayed.

Each SN consists of up to 32 characters; the format for the SN is not case-sensitive.

Considerations when configuring multipath tape access in ONTAP

You can configure two paths from the storage system to access the tape drives in a tape library. If one path fails, the storage system can use the other paths to access the tape drives without having to immediately repair the failed path. This ensures that tape operations can be restarted.

You must consider the following when configuring multipath tape access from your storage system:

- In tape libraries that support LUN mapping, for multipath access to a LUN group, LUN mapping must be symmetrical on each path.

  Tape drives and media changers are assigned to LUN groups (set of LUNs that share the same initiator path set) in a tape library. All tape drives of a LUN group must be available for backup and restore operations on all multiple paths.

- A maximum of two paths can be configured from the storage system to access the tape drives in a tape library.
- Multipath tape access supports load balancing. Load balancing is disabled by default.

In the following example, the storage system accesses LUN group 0 through two initiator paths: 0b and 0d. In both these paths, the LUN group has the same LUN number, 0, and LUN count, 5. The storage system accesses LUN group 1 through only one initiator path, 3d.

```

Learn more about `storage tape library config show` in the ONTAP command reference.

How you add tape drives and libraries to storage systems

You can add tape drives and libraries to storage system dynamically (without taking the storage system offline).

When you add a new medium changer, the storage system detects its presence and adds it to the configuration. If the medium changer is already referenced in the alias information, no new logical names are created. If the library is not referenced, the storage system creates a new alias for the medium changer.

In a tape library configuration, you must configure a tape drive or medium changer on LUN 0 of a target port for ONTAP to discover all medium changers and tape drives on that target port.

What tape reservations are

Multiple storage systems can share access to tape drives, medium changers, bridges, or tape libraries. Tape reservations ensure that only one storage system accesses a device at any particular time by enabling either the SCSI Reserve/Release mechanism or SCSI Persistent Reservations for all tape drives, medium changers, bridges, and tape libraries.

> All the systems that share devices in a library, whether switches are involved or not, must use the same reservation method.

The SCSI Reserve/Release mechanism for reserving devices works well under normal conditions. However, during interface error recovery procedures, reservations can be lost. If this occurs, initiators other than the reserved owner can access the device.

Reservations made with SCSI Persistent Reservations are not affected by error recovery mechanisms, such as loop reset or target reset; however, not all devices implement SCSI Persistent Reservations correctly.

Transfer data between storage systems

Transfer data using ndmpcopy

The `ndmpcopy` nodeshell command transfers data between storage systems that support NDMP v4. You can perform both full and incremental data transfers. You can transfer full or partial volumes, qtrees, directories, or individual files.

About this task

Using ONTAP 8.x and earlier releases, incremental transfers are limited to a maximum of two levels (one full and up to two incremental backups).

Beginning with ONTAP 9.0 and later releases, incremental transfers are limited to a maximum of nine levels (one full and up to nine incremental backups).

You can run `ndmpcopy` at the nodeshell command line of the source and destination storage systems, or a storage system that is neither the source nor the destination of the data transfer. You can also run `ndmpcopy` on a single storage system that is both the source and the destination of the data transfer.

You can use IPv4 or IPv6 addresses of the source and destination storage systems in the `ndmpcopy` command. The path format is `/vserver_name/volume_name \[path\]`.

Learn more about the options you can use with the `ndmpcopy` command.

Steps

1. Enable NDMP service on the source and destination storage systems:

If you are performing data transfer at the source or destination in…	Use the following command…
SVM-scoped NDMP mode	`vserver services ndmp on` For NDMP authentication in the admin SVM, the user account is `admin` and the user role is `admin` or `backup`. In the data SVM, the user account is `vsadmin` and the user role is `vsadmin` or `vsadmin-backup` role.
Node-scoped NDMP mode	`system services ndmp on`

2. Transfer data within a storage system or between storage systems using the `ndmpcopy` command at the nodeshell:

```
::> system node run -node <node_name> < ndmpcopy [options]
source_IP:source_path destination_IP:destination_path [-mcs {inet|inet6}] [-
mcd {inet|inet6}] [-md {inet|inet6}]
```

> DNS names are not supported in ndmpcopy. You must provide the IP address of the source and the destination. The loopback address (127.0.0.1) is not supported for the source IP address or the destination IP address.

- The `ndmpcopy` command determines the address mode for control connections as follows:
  - The address mode for control connection corresponds to the IP address provided.
  - You can override these rules by using the `-mcs` and `-mcd` options.
- If the source or the destination is the ONTAP system, then depending on the NDMP mode (node-scoped or SVM-scoped), use an IP address that allows access to the target volume.
- `source_path` and `destination_path` are the absolute path names till the granular level of volume, qtree, directory or file.
- `-mcs` specifies the preferred addressing mode for the control connection to the source storage system.

  `inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.
- `-mcd` specifies the preferred addressing mode for the control connection to the destination storage system.

  `inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.
- `-md` specifies the preferred addressing mode for data transfers between the source and the destination storage systems.

  `inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.

If you do not use the `-md` option in the `ndmpcopy` command, the addressing mode for the data connection is determined as follows:

- If either of the addresses specified for the control connections is an IPv6 address, the address mode for the data connection is IPv6.
- If both the addresses specified for the control connections are IPv4 addresses, the `ndmpcopy` command first attempts an IPv6 address mode for the data connection.

  If that fails, the command uses an IPv4 address mode.

  An IPv6 address, if specified, must be enclosed within square brackets.

  This sample command migrates data from a source path (`source_path`) to a destination path (`destination_path`).

```
> ndmpcopy -sa admin:<ndmp_password> -da admin:<ndmp_password>
 -st md5 -dt md5 192.0.2.129:/<src_svm>/<src_vol>
192.0.2.131:/<dst_svm>/<dst_vol>
```

  This sample command explicitly sets the control connections and the data connection to use IPv6 address mode:

```
> ndmpcopy -sa admin:<ndmp_password> -da admin:<ndmp_password> -st
md5 -dt md5 -mcs inet6 -mcd inet6 -md
 inet6 [2001:0db8:1:1:209:6bff:feae:6d67]:/<src_svm>/<src_vol>
[2001:0ec9:1:1:200:7cgg:gfdf:7e78]:/<dst_svm>/<dst_vol>
```

Learn more about the commands described in this procedure in the ONTAP command reference.

Options for the ndmpcopy command

You should understand the options available for the `ndmpcopy` nodeshell command to successfully transfer data.

The following table lists the available options.

Option	Description
`-sa username`:[`password`]	This option sets the source authentication user name and password for connecting to the source storage system. This is a mandatory option. For a user without admin privilege, you must specify the user’s system-generated NDMP-specific password. The system-generated password is mandatory for both admin and non-admin users.

Option	Description
`-da username:[password]`	This option sets the destination authentication user name and password for connecting to the destination storage system. This is a mandatory option.
`-st {md5|text}`	This option sets the source authentication type to be used when connecting to the source storage system.This is a mandatory option and therefore the user should provide either the `text` or `md5` option.
`-dt {md5|text}`	This option sets the destination authentication type to be used when connecting to the destination storage system.
`-l`	This option sets the dump level used for the transfer to the specified value of level.Valid values are `0`, `1`, to `9`, where `0` indicates a full transfer and `1` to `9` specifies an incremental transfer. The default is `0`.
`-d`	This option enables generation of ndmpcopy debug log messages. The ndmpcopy debug log files are located in the `/mroot/etc/log` root volume. The ndmpcopy debug log file names are in the `ndmpcopy.yyyymmdd` format.
`-f`	This option enables the forced mode. This mode enables system files to be overwritten in the `/etc` directory on the root of the 7-Mode volume.
`-h`	This option prints the help message.
`-p`	This option prompts you to enter the password for source and destination authorization. This password overrides the password specified for `-sa` and `-da` options. ⓘ You can use this option only when the command is running in an interactive console.
`-exclude`	This option excludes specified files or directories from the path specified for data transfer. The value can be a comma-separated list of directory or file names such as **`.pst`** `or .txt`. The maximum number of exclude patterns supported is 32 and the maximum number of characters supported is 255.

NDMP for FlexVol volumes

About NDMP for FlexVol volumes

The Network Data Management Protocol (NDMP) is a standardized protocol for controlling backup, recovery, and other types of data transfer between primary and secondary storage devices, such as storage systems and tape libraries.

By enabling NDMP support on a storage system, you enable that storage system to communicate with NDMP-enabled network-attached backup applications (also called *Data Management Applications* or *DMAs*), data servers, and tape servers participating in backup or recovery operations. All network communications occur over TCPIP or TCP/IPv6 network. NDMP also provides low-level control of tape drives and medium changers.

You can perform tape backup and restore operations in either node-scoped NDMP mode or storage virtual machine (SVM) scoped NDMP mode.

You must be aware of the considerations that you have to take into account while using NDMP, list of environment variables, and supported NDMP tape backup topologies. You can also enable or disable the enhanced DAR functionality. The two authentication methods supported by ONTAP for authenticating NDMP access to a storage system are: plaintext and challenge.

Related information

Environment variables supported by ONTAP

About NDMP modes of operation

About NDMP modes of operation

You can choose to perform tape backup and restore operations either at the node level or at the storage virtual machine (SVM) level. To perform these operations successfully at the SVM level, NDMP service must be enabled on the SVM.

If you upgrade from Data ONTAP 8.2 to Data ONTAP 8.3, the NDMP mode of operation used in 8.2 will continue to be retained post the upgrade from 8.2 to 8.3.

If you install a new cluster with Data ONTAP 8.2 or later, NDMP is in the SVM-scoped NDMP mode by default. To perform tape backup and restore operations in the node-scoped NDMP mode, you must explicitly enable the node-scoped NDMP mode.

Related information

Commands for managing node-scoped NDMP mode

Managing node-scoped NDMP mode for FlexVol volumes

Managing SVM-scoped NDMP mode for FlexVol volumes

What node-scoped NDMP mode is

In the node-scoped NDMP mode, you can perform tape backup and restore operations at the node level. The NDMP mode of operation used in Data ONTAP 8.2 will continue to be retained post the upgrade from 8.2 to 8.3.

In the node-scoped NDMP mode, you can perform tape backup and restore operations on a node that owns the volume. To perform these operations, you must establish NDMP control connections on a LIF hosted on the node that owns the volume or tape devices.

> This mode is deprecated and will be removed in a future major release.

Related information

Managing node-scoped NDMP mode for FlexVol volumes

What SVM-scoped NDMP mode is

You can perform tape backup and restore operations at the storage virtual machine (SVM) level successfully if the NDMP service is enabled on the SVM. You can back up and restore all volumes hosted across different nodes in the SVM of a cluster if the backup application supports the CAB extension.

An NDMP control connection can be established on different LIF types. In the SVM-scoped NDMP mode, these LIFs belong to either the data SVM or admin SVM. The connection can be established on a LIF only if the NDMP service is enabled on the SVM that owns this LIF.

A data LIF belongs to the data SVM and the intercluster LIF, node-management LIF, and cluster-management LIF belong to the admin SVM.

In the SVM-scoped NDMP mode, the availability of volumes and tape devices for backup and restore operations depends on the LIF type on which the NDMP control connection is established and the status of the CAB extension. If your backup application supports the CAB extension and a volume and the tape device share the same affinity, then the backup application can perform a local backup or restore operation, instead of a three-way backup or restore operation.

Related information

Managing SVM-scoped NDMP mode for FlexVol volumes

Considerations when using NDMP

You must take into account a number of considerations when starting the NDMP service on your storage system.

- Each node supports a maximum of 16 concurrent backups, restores, or combination of the two using connected tape drives.
- NDMP services can generate file history data at the request of NDMP backup applications.

  File history is used by backup applications to enable optimized recovery of selected subsets of data from a backup image. File history generation and processing might be time-consuming and CPU-intensive for both the storage system and the backup application.

  > SMTape does not support file history.

  If your data protection is configured for disaster recovery—where the entire backup image will be recovered—you can disable file history generation to reduce backup time. See your backup application documentation to determine whether it is possible to disable NDMP file history generation.

- Firewall policy for NDMP is enabled by default on all LIF types.

- In node-scoped NDMP mode, backing up a FlexVol volume requires that you use the backup application to initiate a backup on a node that owns the volume.

  However, you cannot back up a node root volume.

- You can perform NDMP backup from any LIF as permitted by the firewall policies.

  If you use a data LIF, you must select a LIF that is not configured for failover. If a data LIF fails over during an NDMP operation, the NDMP operation fails and must be run again.

- In node-scoped NDMP mode and storage virtual machine (SVM) scoped NDMP mode with no CAB extension support, the NDMP data connection uses the same LIF as the NDMP control connection.
- During LIF migration, ongoing backup and restore operations are disrupted.

  You must initiate the backup and restore operations after the LIF migration.

- The NDMP backup path is of the format `/vserver_name/volume_name/path_name`.

  `path_name` is optional, and specifies the path of the directory, file, or snapshot.

- When a SnapMirror destination is backed up to tape by using the dump engine, only the data in the volume is backed up.

  However, if a SnapMirror destination is backed up to tape using SMTape, then the metadata is also backed up. The SnapMirror relationships and the associated metadata are not backed up to tape. Therefore, during restore, only the data on that volume is restored, but the associated SnapMirror relationships are not restored.

What Cluster Aware Backup extension does

System administration

Environment variable

Environment variables overview

Environment variables are used to communicate information about a backup or restore operation between an NDMP-enabled backup application and a storage system.

For example, if a user specifies that a backup application should back up `/vserver1/vol1/dir1`, the backup application sets the FILESYSTEM environment variable to `/vserver1/vol1/dir1`. Similarly, if a user specifies that a backup should be a level 1 backup, the backup application sets the LEVEL environment variable to 1 (one).

> ⓘ The setting and examining of environment variables are typically transparent to backup administrators; that is, the backup application sets them automatically.

A backup administrator rarely specifies environment variables; however, you might want to change the value of an environment variable from that set by the backup application to characterize or work around a functional or performance problem. For example, an administrator might want to temporarily disable file history generation to determine if the backup application’s processing of file history information is contributing to performance issues or functional problems.

Many backup applications provide a means to override or modify environment variables or to specify additional environment variables. For information, see your backup application documentation.

Environment variables supported by ONTAP

Environment variables are used to communicate information about a backup or restore operation between an NDMP-enabled backup application and a storage system. ONTAP supports environment variables, which have an associated default value. However, you can manually modify these default values.

If you manually modify the values set by the backup application, the application might behave unpredictably. This is because the backup or restore operations might not be doing what the backup application expected them to do. But in some cases, judicious modification might help in identifying or working around problems.

The following tables list the environment variables whose behavior is common to dump and SMTape and those variables that are supported only for dump and SMTape. These tables also contain descriptions of how the environment variables that are supported by ONTAP work if they are used:

> In most cases, variables that have the value, `Y` also accept `T` and `N` also accept `F`.

Environment variables supported for dump and SMTape

Environment variable	Valid values	Default	Description
DEBUG	`Y` or `N`	`N`	Specifies that debugging information is printed.
FILESYSTEM	`string`	`none`	Specifies the path name of the root of the data that is being backed up.
NDMP_VERSION	`return_only`	`none`	You should not modify the NDMP_VERSION variable. Created by the backup operation, the NDMP_VERSION variable returns the NDMP version. ONTAP sets the NDMP_VERSION variable during a backup for internal use and to pass to a backup application for informational purposes. The NDMP version of an NDMP session is not set with this variable.

Environment variable	Valid values	Default	Description
PATHNAME_SEPARATOR	`return_value`	`none`	Specifies the path name separator character. This character depends on the file system being backed up. For ONTAP, the character “/” is assigned to this variable. The NDMP server sets this variable before starting a tape backup operation.
TYPE	`dump` or `smtape`	`dump`	Specifies the type of backup supported to perform tape backup and restore operations.
VERBOSE	`Y` or `N`	`N`	Increases the log messages while performing a tape backup or restore operation.

Environment variables supported for dump

Environment variable	Valid values	Default	Description
ACL_START	`return_only`	`none`	Created by the backup operation, the ACL_START variable is an offset value used by a direct access restore or restartable NDMP backup operation. The offset value is the byte offset in the dump file where the ACL data (Pass V) begins and is returned at the end of a backup. For a direct access restore operation to correctly restore backed-up data, the ACL_START value must be passed to the restore operation when it begins. An NDMP restartable backup operation uses the ACL_START value to communicate to the backup application where the nonrestartable portion of the backup stream begins.
BASE_DATE	`0`, `-1`, or `DUMP_DATE` value	`-1`	Specifies the start date for incremental backups. When set to `-1`, the BASE_DATE incremental specifier is disabled. When set to `0` on a level 0 backup, incremental backups are enabled. After the initial backup, the value of the DUMP_DATE variable from the previous incremental backup is assigned to the BASE_DATE variable. These variables are an alternative to the LEVEL/UPDATE based incremental backups.

Environment variable	Valid values	Default	Description
DIRECT	`Y` or `N`	`N`	Specifies that a restore should fast-forward directly to the location on the tape where the file data resides instead of scanning the entire tape. For direct access recovery to work, the backup application must provide positioning information. If this variable is set to `Y`, the backup application specifies the file or directory names and the positioning information.
DMP_NAME	`string`	`none`	Specifies the name for a multiple subtree backup. This variable is mandatory for multiple subtree backups.
DUMP_DATE	`return_value`	`none`	You do not change this variable directly. It is created by the backup if the BASE_DATE variable is set to a value other than `-1`. The DUMP_DATE variable is derived by prepending the 32-bit level value to a 32-bit time value computed by the dump software. The level is incremented from the last level value passed into the BASE_DATE variable. The resulting value is used as the BASE_DATE value on a subsequent incremental backup.

Environment variable	Valid values	Default	Description
ENHANCED_DAR_ENABLED	`Y` or `N`	`N`	Specifies whether enhanced DAR functionality is enabled. Enhanced DAR functionality supports directory DAR and DAR of files with NT Streams. It provides performance improvements. Enhanced DAR during restore is possible only if the following conditions are met: • ONTAP supports enhanced DAR. • File history is enabled (HIST=Y) during the backup. • The `ndmpd.offset_map.enable` option is set to `on`. • ENHANCED_DAR_ENABLED variable is set to `Y` during restore.

Environment variable	Valid values	Default	Description
EXCLUDE	`pattern_string`	`none`	Specifies files or directories that are excluded when backing up data. The exclude list is a comma-separated list of file or directory names. If the name of a file or directory matches one of the names in the list, it is excluded from the backup. The following rules apply while specifying names in the exclude list: • The exact name of the file or directory must be used. • The asterisk (*), a wildcard character, must be either the first or the last character of the string. Each string can have up to two asterisks. • A comma in a file or directory name must be preceded with a backslash. • The exclude list can contain up to 32 names. ⓘ Files or directories specified to be excluded for backup are not excluded if you set NON_QUOTA_TREE to `Y` simultaneously.

Environment variable	Valid values	Default	Description
EXTRACT	`Y`, `N`, or `E`	`N`	Specifies that subtrees of a backed-up data set are to be restored. The backup application specifies the names of the subtrees to be extracted. If a file specified matches a directory whose contents were backed up, the directory is recursively extracted. To rename a file, directory, or qtree during restore without using DAR, you must set the EXTRACT environment variable to `E`.
EXTRACT_ACL	`Y` or `N`	`Y`	Specifies that ACLs from the backed up file are restored on a restore operation. The default is to restore ACLs when restoring data, except for DARs (DIRECT=Y).

Environment variable	Valid values	Default	Description
FORCE	`Y` or `N`	`N`	Determines if the restore operation must check for volume space and inode availability on the destination volume. Setting this variable to `Y` causes the restore operation to skip checks for volume space and inode availability on the destination path. If enough volume space or inodes are not available on the destination volume, the restore operation recovers as much data allowed by the destination volume space and inode availability. The restore operation stops when volume space or inodes are not available.
HIST	`Y` or `N`	`N`	Specifies that file history information is sent to the backup application. Most commercial backup applications set the HIST variable to `Y`. If you want to increase the speed of a backup operation, or you want to troubleshoot a problem with the file history collection, you can set this variable to `N`. You should not set the HIST variable to `Y` if the backup application does not support file history.

Environment variable	Valid values	Default	Description
IGNORE_CTIME	`Y` or `N`	`N`	Specifies that a file is not incrementally backed up if only its ctime value has changed since the previous incremental backup. Some applications, such as virus scanning software, change the ctime value of a file within the inode, even though the file or its attributes have not changed. As a result, an incremental backup might back up files that have not changed. The `IGNORE_CTIME` variable should be specified only if incremental backups are taking an unacceptable amount of time or space because the ctime value was modified. ⓘ The `NDMP dump` command sets `IGNORE_CTIME` to `false` by default. Setting it to `true` can result in the following data loss: 1. If `IGNORE_CTIME` is set to true with a volume level incremental `ndmpcopy`, it results in the deleting

Environment variable	Valid values	Default	Description
IGNORE_QTREES	`Y` or `N`	`N`	Specifies that the restore operation does not restore qtree information from backed-up qtrees.
LEVEL	`0-31`	`0`	Specifies the backup level. Level 0 copies the entire data set. Incremental backup levels, specified by values above 0, copy all files (new or modified) since the last incremental backup. For example, a level 1 backs up new or modified files since the level 0 backup, a level 2 backs up new or modified files since the level 1 backup, and so on.
LIST	`Y` or `N`	`N`	Lists the backed-up file names and inode numbers without actually restoring the data.
LIST_QTREES	`Y` or `N`	`N`	Lists the backed-up qtrees without actually restoring the data.
MULTI_SUBTREE_ NAMES	`string`	`none`	Specifies that the backup is a multiple subtree backup. Multiple subtrees are specified in the string, which is a newline-separated, null-terminated list of subtree names. Subtrees are specified by path names relative to their common root directory, which must be specified as the last element of the list. If you use this variable, you must also use the DMP_NAME variable.

Environment variable	Valid values	Default	Description
NDMP_UNICODE_ FH	Y or N	N	Specifies that a Unicode name is included in addition to the NFS name of the file in the file history information. This option is not used by most backup applications and should not be set unless the backup application is designed to receive these additional file names. The HIST variable must also be set.
NO_ACLS	Y or N	N	Specifies that ACLs must not be copied when backing up data.

Environment variable	Valid values	Default	Description
NON_QUOTA_TREE	`Y` or `N`	`N`	Specifies that files and directories in qtrees must be ignored when backing up data. When set to `Y`, items in qtrees in the data set specified by the FILESYSTEM variable are not backed up. This variable has an effect only if the FILESYSTEM variable specifies an entire volume. The NON_QUOTA_TREE variable only works on a level 0 backup and does not work if the MULTI_SUBTREE_NAMES variable is specified. Files or directories specified to be excluded for backup are not excluded if you set NON_QUOTA_TREE to `Y` simultaneously.
NOWRITE	`Y` or `N`	`N`	Specifies that the restore operation must not write data to the disk. This variable is used for debugging.

Environment variable	Valid values	Default	Description
RECURSIVE	`Y` or `N`	`Y`	Specifies that directory entries during a DAR restore be expanded. The DIRECT and ENHANCED_DAR_ENABLED environment variables must be enabled (set to `Y`) as well. If the RECURSIVE variable is disabled (set to `N`), only the permissions and ACLs for all the directories in the original source path are restored from tape, not the contents of the directories. If the RECURSIVE variable is set to `N` or the RECOVER_FULL_PATHS variable is set to `Y`, the recovery path must end with the original path. If the RECURSIVE variable is disabled and if there is more than one recovery path, all of the recovery paths must be contained within the longest of the recovery paths. Otherwise, an error message is displayed. For example, the following are valid recovery paths because all of the recovery paths are within `foo/dir1/deepdir/myfile`:

Environment variable	Valid values	Default	Description
RECOVER_FULL_PATHS	`Y` or `N`	`N`	Specifies that the full recovery path will have their permissions and ACLs restored after the DAR. DIRECT and ENHANCED_DAR_ENABLED must be enabled (set to `Y`) as well. If RECOVER_FULL_PATHS is set to `Y`, the recovery path must end with the original path. If directories already exist on the destination volume, their permissions and ACLs will not be restored from tape.
UPDATE	`Y` or `N`	`Y`	Updates the metadata information to enable LEVEL based incremental backup.

Environment variables supported for SMTape

Environment variable	Valid values	Default	Description
BASE_DATE	`DUMP_DATE`	`-1`	Specifies the start date for incremental backups. `BASE_DATE` is a string representation of the reference snapshot identifiers. Using the `BASE_DATE` string, SMTape locates the reference snapshot. `BASE_DATE` is not required for baseline backups. For an incremental backup, the value of the `DUMP_DATE` variable from the previous baseline or incremental backup is assigned to the `BASE_DATE` variable. The backup application assigns the `DUMP_DATE` value from a previous SMTape baseline or incremental backup.
DUMP_DATE	`return_value`	`none`	At the end of an SMTape backup, DUMP_DATE contains a string identifier that identifies the snapshot used for that backup. This snapshot could be used as the reference snapshot for a subsequent incremental backup. The resulting value of DUMP_DATE is used as the BASE_DATE value for subsequent incremental backups.

Environment variable	Valid values	Default	Description
SMTAPE_BACKUP_SET_ID	`string`	`none`	Identifies the sequence of incremental backups associated with the baseline backup. Backup set ID is a 128-bit unique ID that is generated during a baseline backup. The backup application assigns this ID as the input to the `SMTAPE_BACKUP_SET_ID` variable during an incremental backup.
SMTAPE_SNAPSHOT_NAME	Any valid snapshot that is available in the volume	`Invalid`	When the SMTAPE_SNAPSHOT_NAME variable is set to a snapshot, that snapshot and its older snapshots are backed up to tape. For incremental backup, this variable specifies incremental snapshot. The BASE_DATE variable provides the baseline snapshot.
SMTAPE_DELETE_SNAPSHOT	`Y` or `N`	`N`	For a snapshot created automatically by SMTape, when the SMTAPE_DELETE_SNAPSHOT variable is set to `Y`, then after the backup operation is complete, SMTape deletes this snapshot. However, a snapshot created by the backup application will not be deleted.
SMTAPE_BREAK_MIRROR	`Y` or `N`	`N`	When the SMTAPE_BREAK_MIRROR variable is set to `Y`, the volume of type `DP` is changed to a `RW` volume after a successful restore.

Common NDMP tape backup topologies

NDMP supports a number of topologies and configurations between backup applications and storage systems or other NDMP servers providing data (file systems) and tape services.

Storage system-to-local-tape

In the simplest configuration, a backup application backs up data from a storage system to a tape subsystem attached to the storage system. The NDMP control connection exists across the network boundary. The NDMP data connection that exists within the storage system between the data and tape services is called an NDMP local configuration.

Storage system-to-tape attached to another storage system

A backup application can also back up data from a storage system to a tape library (a medium changer with one or more tape drives) attached to another storage system. In this case, the NDMP data connection between the data and tape services is provided by a TCP or TCP/IPv6 network connection. This is called an NDMP three-way storage system-to-storage system configuration.

Storage system-to-network-attached tape library

NDMP-enabled tape libraries provide a variation of the three-way configuration. In this case, the tape library attaches directly to the TCP/IP network and communicates with the backup application and the storage system through an internal NDMP server.

Storage system-to-data server-to-tape or data server-to-storage system-to-tape

NDMP also supports storage system-to-data-server and data-server-to-storage system three-way configurations, although these variants are less widely deployed. Storage system-to-server allows storage system data to be backed up to a tape library attached to the backup application host or to another data server system. The server-to-storage system configuration allows server data to be backed up to a storage system-attached tape library.

Supported NDMP authentication methods

You can specify an authentication method to allow NDMP connection requests. ONTAP supports two methods for authenticating NDMP access to a storage system: plaintext and challenge.

In node-scoped NDMP mode, both challenge and plaintext are enabled by default. However, you cannot disable challenge. You can enable and disable plaintext. In the plaintext authentication method, the login password is transmitted as clear text.

In the storage virtual machine (SVM)-scoped NDMP mode, by default the authentication method is challenge. Unlike the node-scoped NDMP mode, in this mode you can enable and disable both plaintext and challenge authentication methods.

User authentication in a node-scoped NDMP mode

User authentication in the SVM-scoped NDMP mode

NDMP extensions supported by ONTAP

NDMP v4 provides a mechanism for creating NDMP v4 protocol extensions without modifying the core NDMP v4 protocol. You should be aware of the NDMP v4 extensions that are supported by ONTAP.

The following NDMP v4 extensions are supported by ONTAP:

- Cluster Aware Backup (CAB)

  > This extension is supported only in the SVM-scoped NDMP mode.

- Connection Address Extension (CAE) for IPv6 support
- Extension class 0x2050

  This extension supports restartable backup operations and Snapshot Management Extensions.

  > The `NDMP_SNAP_RECOVER` message, which is part of the Snapshot Management Extensions, is used to initiate a recovery operation and to transfer the recovered data from a local snapshot to a local file system location. In ONTAP, this message allows the recovery of volumes and regular files only.
  >
  > The `NDMP_SNAP_DIR_LIST` message enables you to browse through the snapshots of a volume. If a nondisruptive operation takes place while a browsing operation is in progress, the backup application must reinitiate the browsing operation.

NDMP restartable backup extension for a dump supported by ONTAP

You can use the NDMP restartable backup extension (RBE) functionality to restart a backup from a known checkpoint in the data stream before the failure.

What enhanced DAR functionality is

You can use the enhanced direct access recovery (DAR) functionality for directory DAR and DAR of files and NT streams. By default, enhanced DAR functionality is enabled.

Enabling enhanced DAR functionality might impact the backup performance because an offset map has to be created and written onto tape. You can enable or disable enhanced DAR in both the node-scoped and storage virtual machine (SVM)-scoped NDMP modes.

Scalability limits for NDMP sessions in ONTAP

You must be aware of the maximum number of NDMP sessions that can be established simultaneously on storage systems of different system memory capacities. This maximum number depends on the system memory of a storage system.

The limits mentioned in the following table are for the NDMP server. The limits mentioned in the section “Scalability limits for dump backup and restore sessions” are for the dump and restore session.

Scalability limits for dump backup and restore sessions

System memory of a storage system	Maximum number of NDMP sessions
Less than 16 GB	8
Greater than or equal to 16 GB but less than 24 GB	20
Greater than or equal to 24 GB	36

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell).
Learn more about `sysconfig -a` in the ONTAP command reference.

About NDMP for FlexGroup volumes

Beginning with ONTAP 9.7, NDMP is supported on FlexGroup volumes.

Beginning with ONTAP 9.7, the ndmpcopy command is supported for data transfer between FlexVol and FlexGroup volumes.

If you revert from ONTAP 9.7 to an earlier version, the incremental transfer information of the previous transfers is not retained and therefore, you must perform a baseline copy after reverting.

Beginning with ONTAP 9.8, the following NDMP features are supported on FlexGroup volumes:

- The NDMP_SNAP_RECOVER message in the extension class 0x2050 can be used for recovering individual files in a FlexGroup volume.
- NDMP restartable backup extension (RBE) is supported for FlexGroup volumes.
- Environment variables EXCLUDE and MULTI_SUBTREE_NAMES are supported for FlexGroup volumes.

About NDMP with SnapLock volumes

Creating multiple copies of regulated data provides you with redundant recovery scenarios, and by using NDMP dump and restore, it’s possible to preserve the write once, read many (WORM) characteristics of source files on a SnapLock volume.

WORM attributes on the files in a SnapLock volume are preserved when backing up, restoring and copying data; however, WORM attributes are enforced only when restoring to a SnapLock volume. If a backup from a SnapLock volume is restored to a volume other than a SnapLock volume, the WORM attributes are preserved but are ignored and are not enforced by ONTAP.

Manage node-scoped NDMP mode for FlexVol volumes

Manage node-scoped NDMP mode for FlexVol volumes overview in ONTAP

You can manage NDMP at the node level by using NDMP options and commands. You can modify the NDMP options by using the `options` command. You must use NDMP-specific credentials to access a storage system to perform tape backup and restore operations.

Learn more about `options` in the ONTAP command reference.

Commands for managing node-scoped NDMP mode

What node-scoped NDMP mode is

Commands for managing node-scoped NDMP mode in ONTAP

You can use the `system services ndmp` commands to manage NDMP at a node level. Some of these commands are deprecated and will be removed in a future major release.

You can use the following NDMP commands only at the advanced privilege level:

- `system services ndmp service terminate`
- `system services ndmp service start`
- `system services ndmp service stop`
- `system services ndmp log start`
- `system services ndmp log stop`

If you want to…	Use this command…
Enable NDMP service	`system services ndmp on*`
Disable NDMP service	`system services ndmp off*`
Display NDMP configuration	`system services ndmp show*`
Modify NDMP configuration	`system services ndmp modify*`
Display the default NDMP version	`system services ndmp version*`
Display NDMP service configuration	`system services ndmp service show`
Modify NDMP service configuration	`system services ndmp service modify`
Display all NDMP sessions	`system services ndmp status`
Display detailed information about all NDMP sessions	`system services ndmp probe`
Terminate the specified NDMP session	`system services ndmp kill`
Terminate all NDMP sessions	`system services ndmp kill-all`

If you want to…	Use this command…
Change the NDMP password	`system services ndmp password*`
Enable node-scoped NDMP mode	`system services ndmp node-scope-mode on*`
Disable node-scoped NDMP mode	`system services ndmp node-scope-mode off*`
Display the node-scoped NDMP mode status	`system services ndmp node-scope-mode status*`
Forcefully terminate all NDMP sessions	`system services ndmp service terminate`
Start the NDMP service daemon	`system services ndmp service start`
Stop the NDMP service daemon	`system services ndmp service stop`
Start logging for the specified NDMP session	`system services ndmp log start*`
Stop logging for the specified NDMP session	`system services ndmp log stop*`

- These commands are deprecated and will be removed in a future major release.

Learn more about `system services ndmp` in the ONTAP command reference.

User authentication in a node-scoped NDMP mode

In the node-scoped NDMP mode, you must use NDMP specific credentials to access a storage system in order to perform tape backup and restore operations.

The default user ID is “root”. Before using NDMP on a node, you must ensure that you change the default NDMP password associated with the NDMP user. You can also change the default NDMP user ID.

Commands for managing node-scoped NDMP mode

Manage SVM-scoped NDMP mode for FlexVol volumes

Manage SVM-scoped NDMP mode for FlexVol volumes overview in ONTAP

You can manage NDMP on a per SVM basis by using the NDMP options and commands. You can modify the NDMP options by using the `vserver services ndmp modify` command. In the SVM-scoped NDMP mode, user authentication is integrated with the role-based access control mechanism.

You can add NDMP in the allowed or disallowed protocols list by using the `vserver modify` command. By default, NDMP is in the allowed protocols list. If NDMP is added to the disallowed protocols list, NDMP sessions cannot be established.

You can control the LIF type on which an NDMP data connection is established by using the `-preferred -interface-role` option. During an NDMP data connection establishment, NDMP chooses an IP address that belongs to the LIF type as specified by this option. If the IP addresses do not belong to any of these LIF types, then the NDMP data connection cannot be established.
Learn more about `vserver services ndmp modify` in the ONTAP command reference.

Stop logging for the specified NDMP session	`vserver services ndmp log stop` This command is available at the advanced privilege level.

Learn more about `vserver services ndmp` in the ONTAP command reference.

What Cluster Aware Backup extension does

CAB (Cluster Aware Backup) is an NDMP v4 protocol extension. This extension enables the NDMP server to establish a data connection on a node that owns a volume. This also enables the backup application to determine if volumes and tape devices are located on the same node in a cluster.

To enable the NDMP server to identify the node that owns a volume and to establish a data connection on such a node, the backup application must support the CAB extension. CAB extension requires the backup application to inform the NDMP server about the volume to be backed up or restored prior to establishing the data connection. This allows the NDMP server to determine the node that hosts the volume and appropriately establish the data connection.

With the CAB extension supported by the backup application, the NDMP server provides affinity information about volumes and tape devices. Using this affinity information, the backup application can perform a local backup instead of a three-way backup if a volume and tape device are located on the same node in a cluster.

Availability of volumes and tape devices for backup and restore on different LIF types

You can configure a backup application to establish an NDMP control connection on any of the LIF types in a cluster. In the storage virtual machine (SVM)-scoped NDMP mode, you can determine the availability of volumes and tape devices for backup and restore operations depending upon these LIF types and the status of the CAB extension.

The following tables show the availability of volumes and tape devices for NDMP control connection LIF types and the status of the CAB extension:

Availability of volumes and tape devices when CAB extension is not supported by the backup application

NDMP control connection LIF type	Volumes available for backup or restore	Tape devices available for backup or restore
Node-management LIF	All volumes hosted by a node	Tape devices connected to the node hosting the node-management LIF
Data LIF	Only volumes that belong to the SVM hosted by a node that hosts the data LIF	None
Cluster-management LIF	All volumes hosted by a node that hosts the cluster-management LIF	None
Intercluster LIF	All volumes hosted by a node that hosts the intercluster LIF	Tape devices connected to the node hosting the intercluster LIF

Availability of volumes and tape devices when CAB extension is supported by the backup application

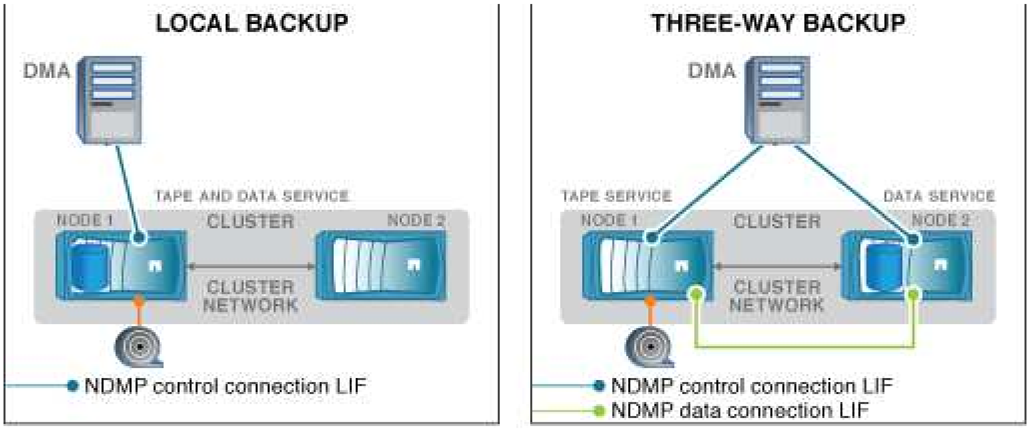
NDMP control connection LIF type	Volumes available for backup or restore	Tape devices available for backup or restore
Node-management LIF	All volumes hosted by a node	Tape devices connected to the node hosting the node-management LIF
Data LIF	All volumes that belong to the SVM that hosts the data LIF	None
Cluster-management LIF	All volumes in the cluster	All tape devices in the cluster
Intercluster LIF	All volumes in the cluster	All tape devices in the cluster

What affinity information is

With the backup application being CAB aware, the NDMP server provides unique location information about volumes and tape devices. Using this affinity information, the backup application can perform a local backup instead of a three-way backup if a volume and a tape device share the same affinity.

If the NDMP control connection is established on a node management LIF, cluster management LIF, or an intercluster LIF, the backup application can use the affinity information to determine if a volume and tape device are located on the same node and then perform either a local or a three-way backup or restore operation. If the NDMP control connection is established on a data LIF, then the backup application always performs a three-way backup.

Local NDMP backup and Three-way NDMP backup



Using the affinity information about volumes and tape devices, the DMA (backup application) performs a local NDMP backup on the volume and tape device located on Node 1 in the cluster. If the volume moves from Node 1 to Node 2, affinity information about the volume and tape device changes. Hence, for a subsequent backup the DMA performs a three-way NDMP backup operation. This ensures continuity of the backup policy for the volume irrespective of the node to which the volume is moved to.

Related information

What Cluster Aware Backup extension does

NDMP server supports secure control connections in SVM-scoped mode

A secure control connection can be established between the Data Management Application (DMA) and NDMP server by using secure sockets (SSL/TLS) as the communication mechanism. This SSL communication is based on the server certificates. The NDMP server listens on port 30000 (assigned by IANA for “ndmps” service).

After establishing the connection from the client on this port, the standard SSL handshake ensues where the server presents the certificate to the client. When the client accepts the certificate, the SSL handshake is complete. After this process is complete, all of the communication between the client and the server is encrypted. The NDMP protocol workflow remains exactly as before. The secure NDMP connection requires server- side certificate authentication only. A DMA can choose to establish a connection either by connecting to the secure NDMP service or the standard NDMP service.

By default, secure NDMP service is disabled for a storage virtual machine (SVM). You can enable or disable the secure NDMP service on a given SVM by using the `vserver services ndmp modify -vserver vserver -is-secure-control-connection-enabled [true|false]` command.

NDMP data connection types

In the storage virtual machine (SVM)-scoped NDMP mode, the supported NDMP data connection types depend on the NDMP control connection LIF type and the status of the CAB extension. This NDMP data connection type indicates whether you can perform a local or a three-way NDMP backup or restore operation.

You can perform a three-way NDMP backup or restore operation over a TCP or TCP/IPv6 network. The following tables show the NDMP data connection types based on the NDMP control connection LIF type and the status of the CAB extension.

NDMP data connection type when CAB extension is supported by the backup application

NDMP control connection LIF type	NDMP data connection type
Node-management LIF	LOCAL, TCP, TCP/IPv6
Data LIF	TCP, TCP/IPv6
Cluster-management LIF	LOCAL, TCP, TCP/IPv6
Intercluster LIF	LOCAL, TCP, TCP/IPv6

NDMP data connection type when CAB extension is not supported by the backup application

NDMP control connection LIF type	NDMP data connection type
Node-management LIF	LOCAL, TCP, TCP/IPv6
Data LIF	TCP, TCP/IPv6
Cluster-management LIF	TCP, TCP/IPv6
Intercluster LIF	LOCAL, TCP, TCP/IPv6

What Cluster Aware Backup extension does

Network management

User authentication in the SVM-scoped NDMP mode

In the storage virtual machine (SVM)-scoped NDMP mode, NDMP user authentication is integrated with role-based access control. In the SVM context, the NDMP user must have either the “vsadmin” or “vsadmin-backup” role. In a cluster context, the NDMP user must have either the “admin” or “backup” role.

Apart from these pre-defined roles, a user account associated with a custom role can also be used for NDMP authentication provided that the custom role has the “vserver services ndmp” folder in its command directory and the access level of the folder is not “none”. In this mode, you must generate an NDMP password for a given user account, which is created through role-based access control. Cluster users in an admin or backup role can access a node-management LIF, a cluster-management LIF, or an intercluster LIF. Users in a vsadmin-backup or vsadmin role can access only the data LIF for that SVM. Therefore, depending on the role of a user, the availability of volumes and tape devices for backup and restore operations vary.

This mode also supports user authentication for NIS and LDAP users. Therefore, NIS and LDAP users can access multiple SVMs with a common user ID and password. However, NDMP authentication does not support Active Directory users.

In this mode, a user account must be associated with the SSH application and the “User password” authentication method.

System administration

Generate an NDMP-specific password for NDMP users

In the storage virtual machine (SVM)-scoped NDMP mode, you must generate a password for a specific user ID. The generated password is based on the actual login password for the NDMP user. If the actual login password changes, you must generate the NDMP-specific password again.

Steps

1. Use the `vserver services ndmp generate-password` command to generate an NDMP-specific password.

   You can use this password in any current or future NDMP operation that requires password input.

   > From the storage virtual machine (SVM, formerly known as Vserver) context, you can generate NDMP passwords for users belonging only to that SVM.

   The following example shows how to generate an NDMP-specific password for a user ID user1:

   ```
   cluster1::vserver services ndmp> generate-password -vserver vs1 -user
   user1

   Vserver: vs1
   User: user1
   Password: jWZiNt57huPOoD8d
   ```

2. If you change the password to your regular storage system account, repeat this procedure to obtain your new NDMP-specific password.

How tape backup and restore operations are affected during disaster recovery in MetroCluster configuration

You can perform tape backup and restore operations simultaneously during disaster recovery in a MetroCluster configuration. You must understand how these operations are affected during disaster recovery.

If tape backup and restore operations are performed on a volume of anSVM in a disaster recovery relationship, then you can continue performing incremental tape backup and restore operations after a switchover and switchback.

About dump engine for FlexVol volumes

About dump engine for FlexVol volumes

Dump is a snapshot based backup and recovery solution from ONTAP that helps you to back up files and directories from a snapshot to a tape device and restore the backed up data to a storage system.

You can back up your file system data, such as directories, files, and their associated security settings, to a tape device by using the dump backup. You can back up an entire volume, an entire qtree, or a subtree that is neither an entire volume nor an entire qtree.

You can perform a dump backup or restore by using NDMP-compliant backup applications.

When you perform a dump backup, you can specify the snapshot to be used for a backup. If you do not specify a snapshot for the backup, the dump engine creates a snapshot for the backup. After the backup operation is completed, the dump engine deletes this snapshot.

You can perform level-0, incremental, or differential backups to tape by using the dump engine.

> After reverting to a release earlier than Data ONTAP 8.3, you must perform a baseline backup operation before performing an incremental backup operation.

Related information

Upgrade, revert, or downgrade

How a dump backup works

A dump backup writes file system data from disk to tape using a predefined process. You can back up a volume, a qtree, or a subtree that is neither an entire volume nor an entire qtree.

The following table describes the process that ONTAP uses to back up the object indicated by the dump path:

Stage	Action
1	For less than full volume or full qtree backups, ONTAP traverses directories to identify the files to be backed up. If you are backing up an entire volume or qtree, ONTAP combines this stage with Stage 2.
2	For a full volume or full qtree backup, ONTAP identifies the directories in the volumes or qtrees to be backed up.
3	ONTAP writes the directories to tape.
4	ONTAP writes the files to tape.
5	ONTAP writes the ACL information (if applicable) to tape.

The dump backup uses a snapshot of your data for the backup. Therefore, you do not have to take the volume offline before initiating the backup.

The dump backup names each snapshot it creates as `snapshot_for_backup.n`, where `n` is an integer starting at 0. Each time the dump backup creates a snapshot, it increments the integer by 1. The integer is reset to 0 after the storage system is rebooted. After the backup operation is completed, the dump engine deletes this snapshot.

When ONTAP performs multiple dump backups simultaneously, the dump engine creates multiple snapshots. For example, if ONTAP is running two dump backups simultaneously, you find the following snapshots in the volumes from which data is being backed up: `snapshot_for_backup.0` and `snapshot_for_backup.1`.

> When you are backing up from a snapshot, the dump engine does not create an additional snapshot.

Types of data that the dump engine backs up

The dump engine enables you to back up data to tape to guard against disasters or controller disruptions. In addition to backing up data objects such as a files, directories, qtrees, or entire volumes, the dump engine can back up many types of information about each file. Knowing the types of data that the dump engine can back up and the restrictions to take into consideration can help you plan your approach to disaster recovery.

In addition to backing up data in files, the dump engine can back up the following information about each file, as applicable:

- UNIX GID, owner UID, and file permissions
- UNIX access, creation, and modification time
- File type
- File size
- DOS name, DOS attributes, and creation time
- Access control lists (ACLs) with 1,024 access control entries (ACEs)
- Qtree information
- Junction paths

Junction paths are backed up as symbolic links.

- LUN and LUN clones

  You can back up an entire LUN object; however, you cannot back up a single file within the LUN object. Similarly, you can restore an entire LUN object but not a single file within the LUN.

  > The dump engine backs up LUN clones as independent LUNs.

- VM-aligned files

  Backup of VM-aligned files is not supported in releases earlier than Data ONTAP 8.1.2.

> When a snapshot-backed LUN clone is transitioned from Data ONTAP operating in 7-Mode to ONTAP, it becomes an inconsistent LUN. The dump engine does not back up inconsistent LUNs.

When you restore data to a volume, client I/O is restricted on the LUNs being restored. The LUN restriction is removed only when the dump restore operation is complete. Similarly, during a SnapMirror single file or LUN restore operation, client I/O is restricted on both files and LUNs being restored. This restriction is removed only when the single file or LUN restore operation is complete. If a dump backup is performed on a volume on which a dump restore or SnapMirror single file or LUN restore operation is being performed, then the files or LUNs that have client I/O restriction are not included in the backup. These files or LUNs are included in a subsequent backup operation if the client I/O restriction is removed.

> A LUN running on Data ONTAP 8.3 that is backed up to tape can be restored only to 8.3 and later releases and not to an earlier release. If the LUN is restored to an earlier release, then the LUN is restored as a file.

When you back up a SnapVault secondary volume or a volume SnapMirror destination to tape, only the data on the volume is backed up. The associated metadata is not backed up. Therefore, when you try to restore the volume, only the data on that volume is restored. Information about the volume SnapMirror relationships is not available in the backup and therefore is not restored.

If you dump a file that has only Windows NT permissions and restore it to a UNIX-style qtree or volume, the file gets the default UNIX permissions for that qtree or volume.

If you dump a file that has only UNIX permissions and restore it to an NTFS-style qtree or volume, the file gets the default Windows permissions for that qtree or volume.

Other dumps and restores preserve permissions.

You can back up VM-aligned files and the `vm-align-sector` option. For more information about VM-aligned files, see Logical storage management.

What increment chains are

An increment chain is a series of incremental backups of the same path. Because you can specify any level of backup at any time, you must understand increment chains to be able to perform backups and restores effectively. You can perform 31 levels of incremental backup operations.

There are two types of increment chains:

- A consecutive increment chain, which is a sequence of incremental backups that starts with level 0 and is raised by 1 at each subsequent backup.
- A nonconsecutive increment chain, where incremental backups skip levels or have levels that are out of sequence, such as 0, 2, 3, 1, 4, or more commonly 0, 1, 1, 1 or 0, 1, 2, 1, 2.

Incremental backups are based on the most recent lower-level backup. For example, the sequence of backup levels 0, 2, 3, 1, 4 provides two increment chains: 0, 2, 3 and 0, 1, 4. The following table explains the bases of the incremental backups:

Backup order	Increment level	Increment chain	Base	Files backed up
1	0	Both	Files on the storage system	All files in the backup path
2	2	0, 2, 3	Level-0 backup	Files in the backup path created since the level-0 backup
3	3	0, 2, 3	Level-2 backup	Files in the backup path created since the level-2 backup
4	1	0, 1, 4	Level-0 backup, because this is the most recent level that is lower than the level-1 backup	Files in the backup path created since the level-0 backup, including files that are in the level-2 and level-3 backups
5	4	0, 1, 4	The level-1 backup, because it is a lower level and is more recent than the level-0, level-2, or level-3 backups	Files created since the level-1 backup

What the blocking factor is

A tape block is 1,024 bytes of data. During a tape backup or restore, you can specify the number of tape blocks that are transferred in each read/write operation. This number is called the *blocking factor*.

You can use a blocking factor from 4 to 256. If you plan to restore a backup to a system other than the system that did the backup, the restore system must support the blocking factor that you used for the backup. For example, if you use a blocking factor of 128, the system on which you restore that backup must support a blocking factor of 128.

During an NDMP backup, the MOVER_RECORD_SIZE determines the blocking factor. ONTAP allows a maximum value of 256 KB for MOVER_RECORD_SIZE.

When to restart a dump backup

A dump backup sometimes does not finish because of internal or external errors, such as tape write errors, power outages, accidental user interruptions, or internal inconsistency on the storage system. If your backup fails for one of these reasons, you can restart it.

You can choose to interrupt and restart a backup to avoid periods of heavy traffic on the storage system or to avoid competition for other limited resources on the storage system, such as a tape drive. You can interrupt a long backup and restart it later if a more urgent restore (or backup) requires the same tape drive. Restartable backups persist across reboots. You can restart an aborted backup to tape only if the following conditions are true:

- The aborted backup is in phase IV.
- All of the associated snapshots that were locked by the dump command are available.
- The file history must be enabled.

When such a dump operation is aborted and left in a restartable state, the associated snapshots are locked. These snapshots are released after the backup context is deleted. You can view the list of backup contexts by using the `vserver services ndmp restartable backup show` command.

```
cluster::> vserver services ndmpd restartable-backup show
Vserver     Context Identifier                   Is Cleanup Pending?
----------- ------------------------------------ -------------------
vserver1 330e6739-0179-11e6-a299-005056bb4bc9 false
vserver1 481025c1-0179-11e6-a299-005056bb4bc9 false
vserver2 5cf10132-0179-11e6-a299-005056bb4bc9 false
3 entries were displayed.

cluster::> vserver services ndmpd restartable-backup show -vserver

How a dump restore works

A dump restore writes file system data from tape to disk using a predefined process.

The process in the following table shows how the dump restore works:

Stage	Action
1	ONTAP catalogs the files that need to be extracted from the tape.
2	ONTAP creates directories and empty files.
3	ONTAP reads a file from tape, writes it to disk, and sets the permissions (including ACLs) on it.
4	ONTAP repeats stages 2 and 3 until all the specified files are copied from the tape.

Types of data that the dump engine restores

When a disaster or controller disruption occurs, the dump engine provides multiple methods for you to recover all of the data that you backed up, from single files, to file attributes, to entire directories. Knowing the types of data that dump engine can restore and when to use which method of recovery can help minimize downtime.

You can restore data to an online mapped LUN. However, host applications cannot access this LUN until the restore operation is complete. After the restore operation is complete, the host cache of the LUN data should be flushed to provide coherency with the restored data.

The dump engine can recover the following data:

- Contents of files and directories
- UNIX file permissions
- ACLs

  If you restore a file that has only UNIX file permissions to an NTFS qtree or volume, the file has no Windows NT ACLs. The storage system uses only the UNIX file permissions on this file until you create a Windows NT ACL on it.

  > If you restore ACLs backed up from storage systems running Data ONTAP 8.2 to storage systems running Data ONTAP 8.1.x and earlier that have an ACE limit lower than 1,024, a default ACL is restored.

- Qtree information

  Qtree information is used only if a qtree is restored to the root of a volume. Qtree information is not used if a qtree is restored to a lower directory, such as `/vs1/vol1/subdir/lowerdir`, and it ceases to be a qtree.

- All other file and directory attributes
- Windows NT streams
- LUNs
  - A LUN must be restored to a volume level or a qtree level for it to remain as a LUN.

If it is restored to a directory, it is restored as a file because it does not contain any valid metadata.

    ◦ A 7-Mode LUN is restored as a LUN on an ONTAP volume.

- A 7-Mode volume can be restored to an ONTAP volume.
- VM-aligned files restored to a destination volume inherit the VM-align properties of the destination volume.
- The destination volume for a restore operation might have files with mandatory or advisory locks.

  While performing restore operation to such a destination volume, the dump engine ignores these locks.

Considerations before restoring data

You can restore backed-up data to its original path or to a different destination. If you are restoring backed-up data to a different destination, you must prepare the destination for the restore operation.

Before restoring data either to its original path or to a different destination, you must have the following information and meet the following requirements:

- The level of the restore
- The path to which you are restoring the data
- The blocking factor used during the backup
- If you are doing an incremental restore, all tapes must be in the backup chain
- A tape drive that is available and compatible with the tape to be restored from

Before restoring data to a different destination, you must perform the following operations:

- If you are restoring a volume, you must create a new volume.
- If you are restoring a qtree or a directory, you must rename or move files that are likely to have the same names as files you are restoring.

> In ONTAP 9, qtree names support the Unicode format. The earlier releases of ONTAP do not support this format. If a qtree with Unicode names in ONTAP 9 is copied to an earlier release of ONTAP using the `ndmpcopy` command or through restoration from a backup image in a tape, the qtree is restored as a regular directory and not as a qtree with Unicode format.

> If a restored file has the same name as an existing file, the existing file is overwritten by the restored file. However, the directories are not overwritten.

To rename a file, directory, or qtree during restore without using DAR, you must set the EXTRACT environment variable to `E`.

Required space on the destination storage system

You require about 100 MB more space on the destination storage system than the amount of data to be restored.

The restore operation checks for volume space and inode availability on the destination volume when the restore operation starts. Setting the FORCE environment variable to `Y` causes the restore operation to skip the checks for volume space and inode availability on the destination path. If there is not enough volume space or inodes available on the destination volume, the restore operation recovers as much data allowed by the destination volume space and inode availability. The restore operation stops when there is no more volume space or inodes left.

Scalability limits for dump backup and restore sessions in ONTAP

You must be aware of the maximum number of dump backup and restore sessions that can be performed simultaneously on storage systems of different system memory capacities. This maximum number depends on the system memory of a storage system.

The limits mentioned in the following table are for the dump or restore engine. The limits mentioned in the scalability limits for NDMP sessions are for the NDMP server, which are higher than the engine limits.

System memory of a storage system	Total number of dump backup and restore sessions
Less than 16 GB	4
Greater than or equal to 16 GB but less than 24 GB	16
Greater than or equal to 24 GB	32

If you use `ndmpcopy` command to copy data within storage systems, two NDMP sessions are established, one for dump backup and the other for dump restore.

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell).
Learn more about `sysconfig -a` in the ONTAP command reference.

Scalability limits for NDMP sessions

Tape backup and restore support between Data ONTAP operating in 7-Mode and ONTAP

You can restore data backed up from a storage system operating in 7-Mode or running ONTAP to a storage system either operating in 7-Mode or running ONTAP.

The following tape backup and restore operations are supported between Data ONTAP operating in 7-Mode and ONTAP:

- Backing up a 7-Mode volume to a tape drive connected to a storage system running ONTAP
- Backing up an ONTAP volume to a tape drive connected to a 7-Mode system
- Restoring backed-up data of a 7-Mode volume from a tape drive connected to a storage system running ONTAP
- Restoring backed-up data of an ONTAP volume from a tape drive connected to a 7-Mode system

- Restoring a 7-Mode volume to an ONTAP volume

```
-   A 7-Mode LUN is restored as a LUN on an ONTAP volume.
-   You should retain the ONTAP LUN identifiers when
restoring a 7-Mode LUN to an existing ONTAP LUN.
```

- Restoring an ONTAP volume to a 7-Mode volume

An ONTAP LUN is restored as a regular file on a 7-Mode volume.

Delete restartable contexts

If you want to start a backup instead of restarting a context, you can delete the context.

About this task

You can delete a restartable context using the `vserver services ndmp restartable-backup delete` command by providing the SVM name and the context ID.

Steps

1. Delete a restartable context:

   `vserver services ndmp restartable-backup delete -vserver` *`vserver-name`* `-context -id` *`context_identifier`*.

```
cluster::> vserver services ndmpd restartable-backup show
Vserver     Context Identifier                   Is Cleanup Pending?
----------- ------------------------------------ -------------------
vserver1    330e6739-0179-11e6-a299-005056bb4bc9 false
vserver1    481025c1-0179-11e6-a299-005056bb4bc9 false
vserver2    5cf10132-0179-11e6-a299-005056bb4bc9 false
3 entries were displayed.

cluster::>
cluster::> vserver services ndmp restartable-backup delete -vserver
vserver1 -context-id 481025c1-0179-11e6-a299-005056bb4bc9

cluster::> vserver services ndmpd restartable-backup show
Vserver     Context Identifier                   Is Cleanup Pending?
----------- ------------------------------------ -------------------
vserver1    330e6739-0179-11e6-a299-005056bb4bc9 false
vserver2    5cf10132-0179-11e6-a299-005056bb4bc9 false
3 entries were displayed.

cluster::>"
```

How dump works on a SnapVault secondary volume

You can perform tape backup operations on data that is mirrored on the SnapVault secondary volume. You can back up only the data that is mirrored on the SnapVault secondary volume to tape, and not the SnapVault relationship metadata.

When you break the data protection mirror relationship (`snapmirror break`) or when a SnapMirror resynchronization occurs, you must always perform a baseline backup.

Related information

- snapmirror break

How dump works with storage failover and ARL operations

Before you perform dump backup or restore operations, you should understand how these operations work with storage failover (takeover and giveback) or aggregate relocation (ARL) operations. The `-override-vetoes` option determines the behavior of dump engine during a storage failover or ARL operation.

When a dump backup or restore operation is running and the `-override-vetoes` option is set to `false`, a user-initiated storage failover or ARL operation is stopped. However, if the `–override-vetoes` option is set to `true`, then the storage failover or ARL operation is continued and the dump backup or restore operation is aborted. When a storage failover or ARL operation is automatically initiated by the storage system, an active dump backup or restore operation is always aborted. You cannot restart dump backup and restore operations even after storage failover or ARL operations complete.

Dump operations when CAB extension is supported

If the backup application supports CAB extension, you can continue performing incremental dump backup and restore operations without reconfiguring backup policies after a storage failover or ARL operation.

Dump operations when CAB extension is not supported

If the backup application does not support CAB extension, you can continue performing incremental dump backup and restore operations if you migrate the LIF configured in the backup policy to the node that hosts the destination aggregate. Otherwise, after the storage failover and ARL operation, you must perform a baseline backup prior to performing the incremental backup operation.

> For storage failover operations, the LIF configured in the backup policy must be migrated to the partner node.

Related information

High Availability

How dump works with volume move

Tape backup and restore operations and volume move can run in parallel until the final cutover phase is attempted by the storage system. After this phase, new tape backup and restore operations are not allowed on the volume that is being moved. However, the current operations continue to run until completion.

The following table describes the behavior of tape backup and restore operations after the volume move operation:

If you are performing tape backup and restore operations in the…	Then…
storage virtual machine (SVM) scoped NDMP mode when CAB extension is supported by the backup application	You can continue performing incremental tape backup and restore operations on read/write and read-only volumes without reconfiguring backup policies.
SVM-scoped NDMP mode when CAB extension is not supported by the backup application	You can continue performing incremental tape backup and restore operations on read/write and read-only volumes if you migrate the LIF configured in the backup policy to the node that hosts the destination aggregate. Otherwise, after the volume move, you must perform a baseline backup before performing the incremental backup operation.

When a volume move occurs, if the volume belonging to a different SVM on the destination node has the same name as that of the moved volume, then you cannot perform incremental backup operations of the moved volume.

How dump works when a FlexVol volume is full

Before performing an incremental dump backup operation, you must ensure that there is sufficient free space in the FlexVol volume.

If the operation fails, you must increase the free space in the Flex Vol volume either by increasing its size or by deleting the snapshots. Then perform the incremental backup operation again.

How dump works when volume access type changes

When a SnapMirror destination volume or a SnapVault secondary volume changes state from read/write to read-only or from read-only to read/write, you must perform a baseline tape backup or restore operation.

SnapMirror destination and SnapVault secondary volumes are read-only volumes. If you perform tape backup and restore operations on such volumes, you must perform a baseline backup or restore operation whenever the volume changes state from read-only to read/write or from read/write to read-only.

How dump works with SnapMirror single file or LUN restore

Before you perform dump backup or restore operations on a volume to which a single file or LUN is restored by using SnapMirror technology, you must understand how dump operations work with a single file or LUN restore operation.

During a SnapMirror single file or LUN restore operation, client I/O is restricted on the file or LUN being restored. When the single file or LUN restore operation finishes, the I/O restriction on the file or LUN is removed. If a dump backup is performed on a volume to which a single file or LUN is restored, then the file or LUN that has client I/O restriction is not included in the dump backup. In a subsequent backup operation, this file or LUN is backed up to tape after the I/O restriction is removed.

You cannot perform a dump restore and a SnapMirror single file or LUN restore operation simultaneously on the same volume.

How dump backup and restore operations are affected in MetroCluster configurations

Before you perform dump backup and restore operations in a MetroCluster configuration, you must understand how dump operations are affected when a switchover or switchback operation occurs.

Dump backup or restore operation followed by switchover

Consider two clusters: cluster 1 and cluster 2. During a dump backup or restore operation on cluster 1, if a switchover is initiated from cluster 1 to cluster 2, then the following occurs:

- If the value of the `override-vetoes` option is `false`, then the switchover is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the dump backup or restore operation is aborted and the switchover continues.

Dump backup or restore operation followed by switchback

A switchover is performed from cluster 1 to cluster 2 and a dump backup or restore operation is initiated on cluster 2. The dump operation backs up or restores a volume that is located on cluster 2. At this point, if a switchback is initiated from cluster 2 to cluster 1, then the following occurs:

- If the value of the `override-vetoes` option is `false`, then the switchback is cancelled and the backup or restore operation continues.
- If the value of the option is `true`, then the backup or restore operation is aborted and the switchback continues.

Dump backup or restore operation initiated during a switchover or switchback

During a switchover from cluster 1 to cluster 2, if a dump backup or restore operation is initiated on cluster 1, then the backup or restore operation fails and the switchover continues.

During a switchback from cluster 2 to cluster 1, if a dump backup or restore operation is initiated from cluster 2, then the backup or restore operation fails and the switchback continues.

About SMTape engine for FlexVol volumes

About SMTape engine for FlexVol volumes

SMTape is a disaster recovery solution from ONTAP that backs up blocks of data to tape. You can use SMTape to perform volume backups to tapes. However, you cannot perform a backup at the qtree or subtree level. SMTape supports baseline, differential, and incremental backups. SMTape does not require a license.

You can perform an SMTape backup and restore operation by using an NDMP-compliant backup application. You can choose SMTape to perform backup and restore operations only in the storage virtual machine (SVM) scoped NDMP mode.

> Reversion process is not supported when an SMTape backup or restore session is in progress. You must wait until the session finishes or you must abort the NDMP session.

Using SMTape, you can back up 255 snapshots. For subsequent baseline, incremental, or differential backups, you must delete older backed-up snapshots.

Before performing a baseline restore, the volume to which data is being restored must be of type `DP` and this volume must be in the restricted state. After a successful restore, this volume is automatically online. You can perform subsequent incremental or differential restores on this volume in the order in which the backups were performed.

Use snapshots during SMTape backup

You should understand how snapshots are used during an SMTape baseline backup and an incremental backup. There are also considerations to keep in mind while performing a backup using SMTape.

Baseline backup

While performing a baseline backup, you can specify the name of the snapshot to be backed up to tape. If no snapshot is specified, then depending on the access type of the volume (read/write or read-only), either a snapshot is created automatically or existing snapshots are used. When you specify a snapshot for the backup, all the snapshots older than the specified snapshot are also backed up to tape.

If you do not specify a snapshot for the backup, the following occurs:

- For a read/write volume, a snapshot is created automatically.

  The newly created snapshot and all the older snapshots are backed up to tape.

- For a read-only volume, all the snapshots, including the latest snapshot, are backed up to tape.

  Any new snapshots created after the backup is started are not backed up.

Incremental backup

For SMTape incremental or differential backup operations, the NDMP-compliant backup applications create and manage the snapshots.

You must always specify a snapshot while performing an incremental backup operation. For a successful incremental backup operation, the snapshot backed up during the previous backup operation (baseline or incremental) must be on the volume from which the backup is performed. To ensure that you use this backed-up snapshot, you must consider the snapshot policy assigned on this volume while configuring the backup policy.

Considerations on SMTape backups on SnapMirror destinations

- A data protection mirror relationship creates temporary snapshots on the destination volume for replication.

  You should not use these snapshots for SMTape backup.

- If a SnapMirror update occurs on a destination volume in a data protection mirror relationship during an SMTape backup operation on the same volume, then the snapshot that is backed up by SMTape must not be deleted on the source volume.

During the backup operation, SMTape locks the snapshot on the destination volume and if the corresponding snapshot is deleted on the source volume, then the subsequent SnapMirror update operation fails.

- You should not use these snapshots during incremental backup.

SMTape capabilities

SMTape capabilities such as backup of snapshots, incremental and differential backups, preservation of deduplication and compression features on restored volumes, and tape seeding help you optimize your tape backup and restore operations.

SMTape provides the following capabilities:

- Provides a disaster recovery solution
- Enables incremental and differential backups
- Backs up snapshots
- Enables backup and restore of deduplicated volumes and preserves deduplication on the restored volumes
- Backs up compressed volumes and preserves compression on the restored volumes
- Enables tape seeding

SMTape supports the blocking factor in multiples of 4 KB, in the range of 4 KB through 256 KB.

> You can restore data to volumes created across up to two major consecutive ONTAP releases only.

Features not supported in SMTape

SMTape does not support restartable backups and verification of backed-up files.

Scalability limits for SMTape backup and restore sessions in ONTAP

While performing SMTape backup and restore operations through NDMP or CLI (tape seeding), you must be aware of the maximum number of SMTape backup and restore sessions that can be performed simultaneously on storage systems with different system memory capacities. This maximum number depends on the system memory of a storage system.

> SMTape backup and restore sessions scalability limits are different from NDMP session limits and dump session limits.

System memory of the storage system	Total number of SMTape backup and restore sessions
Less than 16 GB	6

System memory of the storage system	Total number of SMTape backup and restore sessions
Greater than or equal to 16 GB but less than 24 GB	16
Greater than or equal to 24 GB	32

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell).
Learn more about `sysconfig -a` in the ONTAP command reference.

- Scalability limits for NDMP sessions
- Scalability limits for dump backup and restore sessions

What tape seeding is

Tape seeding is an SMTape functionality that helps you initialize a destination FlexVol volume in a data protection mirror relationship.

Tape seeding enables you to establish a data protection mirror relationship between a source system and a destination system over a low-bandwidth connection.

Incremental mirroring of snapshots from the source to the destination is feasible over a low bandwidth connection. However, an initial mirroring of the base snapshot takes a long time over a low-bandwidth connection. In such cases, you can perform an SMTape backup of the source volume to a tape and use the tape to transfer the initial base snapshot to the destination. You can then set up incremental SnapMirror updates to the destination system using the low-bandwidth connection.

How SMTape works with storage failover and ARL operations

Before you perform SMTape backup or restore operations, you should understand how these operations work with storage failover (takeover and giveback) or aggregate relocation (ARL) operation. The `-override-vetoes` option determines the behavior of SMTape engine during a storage failover or ARL operation.

When an SMTape backup or restore operation is running and the `-override-vetoes` option is set to `false`, a user-initiated storage failover or ARL operation is stopped and the backup or restore operation complete. If the backup application supports CAB extension, then you can continue performing incremental SMTape backup and restore operations without reconfiguring backup policies. However, if the `-override-vetoes` option is set to `true`, then the storage failover or ARL operation is continued and the SMTape backup or restore operation is aborted.

Related information

Network management

High Availability

How SMTape works with volume move

SMTape backup operations and volume move operations can run in parallel until the storage system attempts the final cutover phase. After this phase, new SMTape backup operations cannot run on the volume that is being moved. However, the current operations continue to run until completion.

Before the cutover phase for a volume is started, the volume move operation checks for active SMTape backup operations on the same volume. If there are active SMTape backup operations, then the volume move operation moves into a cutover deferred state and allows the SMTape backup operations to complete. After these backup operations are completed, you must manually restart the volume move operation.

If the backup application supports CAB extension, you can continue performing incremental tape backup and restore operations on read/write and read-only volumes without reconfiguring backup policies.

Baseline restore and volume move operations cannot be performed simultaneously; however, incremental restore can run in parallel with volume move operations, with the behavior similar to that of SMTape backup operations during volume move operations.

How SMTape works with volume rehost operations

SMTape operations cannot commence when a volume rehost operation is in progress on a volume. When a volume is involved in a volume rehost operation, SMTape sessions should not be started on that volume.

If any volume rehost operation is in progress, then SMTape backup or restore fails. If an SMTape backup or restore is in progress, then volume rehost operations fail with an appropriate error message. This condition applies to both NDMP-based and CLI-based backup or restore operations.

How NDMP backup policy are affected during ADB

When the automatic data balancer (ADB) is enabled, the balancer analyzes the usage statistics of aggregates to identify the aggregate that has exceeded the configured high-threshold usage percentage.

After identifying the aggregate that has exceeded the threshold, the balancer identifies a volume that can be moved to aggregates residing in another node in the cluster and attempts to move that volume. This situation affects the backup policy configured for this volume because if the data management application (DMA) is not CAB aware, then the user has to reconfigure the backup policy and run the baseline backup operation.

> If the DMA is CAB aware and the backup policy has been configured using specific interface, then the ADB is not affected.

How SMTape backup and restore operations are affected in MetroCluster configurations

Before you perform SMTape backup and restore operations in a MetroCluster configuration, you must understand how SMTape operations are affected when a switchover or switchback operation occurs.

SMTape backup or restore operation followed by switchover

Consider two clusters: cluster 1 and cluster 2. During an SMTape backup or restore operation on cluster 1, if a switchover is initiated from cluster 1 to cluster 2, then the following occurs:

- If the value of the `–override-vetoes` option is `false`, then the switchover process is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the SMTape backup or restore operation is aborted and the switchover process continues.

SMTape backup or restore operation followed by switchback

A switchover is performed from cluster 1 to cluster 2 and an SMTape backup or restore operation is initiated on cluster 2. The SMTape operation backs up or restores a volume that is located on cluster 2. At this point, if a switchback is initiated from cluster 2 to cluster 1, then the following occurs:

- If the value of the `–override-vetoes` option is `false`, then the switchback process is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the backup or restore operation is aborted and the switchback process continues.

SMTape backup or restore operation initiated during a switchover or switchback

During a switchover process from cluster 1 to cluster 2, if an SMTape backup or restore operation is initiated on cluster 1, then the backup or restore operation fails and the switchover continues.

During a switchback process from cluster 2 to cluster 1, if an SMTape backup or restore operation is initiated from cluster 2, then the backup or restore operation fails and the switchback continues.

Monitor tape backup and restore operations for FlexVol volumes

Monitor tape backup and restore operations for FlexVol volumes overview

You can view the event log files to monitor the tape backup and restore operations. ONTAP automatically logs significant backup and restore events and the time at which they occur in a log file named `backup` in the controller’s `/etc/log/` directory. By default, event logging is set to `on`.

You might want to view event log files for the following reasons:

- Checking whether a nightly backup was successful
- Gathering statistics on backup operations
- For using the information in past event log files to help diagnose problems with backup and restore operations

Once every week, the event log files are rotated. The `/etc/log/backup` file is renamed to `/etc/log/backup.0`, the `/etc/log/backup.0` file is renamed to `/etc/log/backup.1`, and so on. The system saves the log files for up to six weeks; therefore, you can have up to seven message files (`/etc/log/backup.[0-5]` and the current `/etc/log/backup` file).

Access the event log files

You can access the event log files for tape backup and restore operations in the `/etc/log/` directory by using the `rdfile` command at the nodeshell. You can view these event log files to monitor tape backup and restore operations.

About this task

With additional configurations, such as an access-control role with access to the `spi` web service or a user account set up with the `http` access method, you can also use a web browser to access these log files.

Steps

1. To access the nodeshell, enter the following command:

   `node run -node node_name`

   `node_name` is the name of the node.

2. To access the event log files for tape backup and restore operations, enter the following command:

   `rdfile /etc/log/backup`

What the dump and restore event log message format is

Dump and restore event log message format overview

For each dump and restore event, a message is written to the backup log file.

The format of the dump and restore event log message is as follows:

`type timestamp identifier event (event_info)`

The following list describes the fields in the event log message format:

- Each log message begins with one of the type indicators described in the following table:

Type	Description
log	Logging event
dmp	Dump event
rst	Restore event

- `timestamp` shows the date and time of the event.
- The `identifier` field for a dump event includes the dump path and the unique ID for the dump. The `identifier` field for a restore event uses only the restore destination path name as a unique identifier. Logging-related event messages do not include an `identifier` field.

What logging events are

The event field of a message that begins with a log specifies the beginning of a logging or the end of a logging.

It contains one of the events shown in the following table:

Event	Description
Start_Logging	Indicates the beginning of logging or that logging has been turned back on after being disabled.
Stop_Logging	Indicates that logging has been turned off.

What dump events are

The event field for a dump event contains an event type followed by event-specific information within parentheses.

The following table describes the events, their descriptions, and the related event information that might be recorded for a dump operation:

Event	Description	Event information
Start	NDMP dump is started	Dump level and the type of dump
End	Dumps completed successfully	Amount of data processed
Abort	The operation is cancelled	Amount of data processed
Options	Specified options are listed	All options and their associated values, including NDMP options
Tape_open	The tape is open for read/write	The new tape device name
Tape_close	The tape is closed for read/write	The tape device name
Phase-change	A dump is entering a new processing phase	The new phase name
Error	A dump has encountered an unexpected event	Error message
Snapshot	A snapshot is created or located	The name and time of the snapshot
Base_dump	A base dump entry in the internal metafile has been located	The level and time of the base dump (for incremental dumps only)

What restore events are

The event field for a restore event contains an event type followed by event-specific information in parentheses.

The following table provides information about the events, their descriptions, and the related event information that can be recorded for a restore operation:

Event	Description	Event information
Start	NDMP restore is started	Restore level and the type of restore
End	Restores completed successfully	Number of files and amount of data processed
Abort	The operation is cancelled	Number of files and amount of data processed
Options	Specified options are listed	All options and their associated values, including NDMP options
Tape_open	The tape is open for read/write	The new tape device name
Tape_close	The tape is closed for read/write	The tape device name
Phase-change	Restore is entering a new processing phase	The new phase name
Error	Restore encounters an unexpected event	Error message

Enabling or disabling event logging

You can turn the event logging on or off.

Steps

1. To enable or disable event logging, enter the following command at the clustershell:

   `options -option_name backup.log.enable -option-value {on | off}`

   `on` turns event logging on.

   `off` turns event logging off.

   > Event logging is turned on by default.

Error messages for tape backup and restore of FlexVol volumes

Backup and restore error messages

Resource limitation: no available thread

- **Message**

  `Resource limitation: no available thread`

- **Cause**

  The maximum number of active local tape I/O threads is currently in use. You can have a maximum of 16 active local tape drives.

- **Corrective action**

  Wait for some tape jobs to finish before starting a new backup or restore job.

Tape reservation preempted

- **Message**

  `Tape reservation preempted`

- **Cause**

  The tape drive is in use by another operation or the tape has been closed prematurely.

- **Corrective action**

  Ensure that the tape drive is not in use by another operation and that the DMA application has not aborted the job and then retry.

Could not initialize media

- **Message**

  `Could not initialize media`

- **Cause**

  You might get this error for one of the following reasons:

  - The tape drive used for the backup is corrupt or damaged.
  - The tape does not contain the complete backup or is corrupt.
  - The maximum number of active local tape I/O threads is currently in use.

    You can have a maximum of 16 active local tape drives.

- **Corrective action**
  - If the tape drive is corrupt or damaged, retry the operation with a valid tape drive.

- If the tape does not contain the complete backup or is corrupt, you cannot perform the restore operation.
- If tape resources are not available, wait for some of the backup or restore jobs to finish and then retry the operation.

Maximum number of allowed dumps or restores (maximum session limit) in progress

- **Message**

  `Maximum number of allowed dumps or restores` *`(maximum session limit)`* `in progress`

- **Cause**

  The maximum number of backup or restore jobs is already running.

- **Corrective action**

  Retry the operation after some of the currently running jobs have finished.

Media error on tape write

- **Message**

  `Media error on tape write`

- **Cause**

  The tape used for the backup is corrupted.

- **Corrective action**

  Replace the tape and retry the backup job.

Tape write failed

- **Message**

  `Tape write failed`

- **Cause**

  The tape used for the backup is corrupted.

- **Corrective action**

  Replace the tape and retry the backup job.

Tape write failed - new tape encountered media error

- **Message**

  `Tape write failed - new tape encountered media error`

- **Cause**

  The tape used for the backup is corrupted.

- **Corrective action**

  Replace the tape and retry the backup.

Tape write failed - new tape is broken or write protected

- **Message**

  ```
  Tape write failed - new tape is broken or write protected
  ```

- **Cause**

  The tape used for the backup is corrupted or write-protected.

- **Corrective action**

  Replace the tape and retry the backup.

Tape write failed - new tape is already at the end of media

- **Message**

  ```
  Tape write failed - new tape is already at the end of media
  ```

- **Cause**

  There is not enough space on the tape to complete the backup.

- **Corrective action**

  Replace the tape and retry the backup.

Tape write error

- **Message**

  ```
  Tape write error - The previous tape had less than the required minimum
  capacity, size MB, for this tape operation, The operation should be restarted
  from the beginning
  ```

- **Cause**

  The tape capacity is insufficient to contain the backup data.

- **Corrective action**

  Use tapes with larger capacity and retry the backup job.

Media error on tape read

- **Message**

  `Media error on tape read`

- **Cause**

  The tape from which data is being restored is corrupted and might not contain the complete backup data.

- **Corrective action**

  If you are sure that the tape has the complete backup, retry the restore operation. If the tape does not contain the complete backup, you cannot perform the restore operation.

Tape read error

- **Message**

  `Tape read error`

- **Cause**

  The tape drive is damaged or the tape does not contain the complete backup.

- **Corrective action**

  If the tape drive is damaged, use another tape drive. If the tape does not contain the complete backup, you cannot restore the data.

Already at the end of tape

- **Message**

  `Already at the end of tape`

- **Cause**

  The tape does not contain any data or must be rewound.

- **Corrective action**

  If the tape does not contain data, use the tape that contains the backup and retry the restore job. Otherwise, rewind the tape and retry the restore job.

Tape record size is too small. Try a larger size.

- **Message**

  `Tape record size is too small. Try a larger size.`

- **Cause**

  The blocking factor specified for the restore operation is smaller than the blocking factor that was used during the backup.

- **Corrective action**

  Use the same blocking factor that was specified during the backup.

Tape record size should be block_size1 and not block_size2

- **Message**

  `Tape record size should be block_size1 and not block_size2`

- **Cause**

  The blocking factor specified for the local restore is incorrect.

- **Corrective action**

  Retry the restore job with `block_size1` as the blocking factor.

Tape record size must be in the range between 4KB and 256KB

- **Message**

  `Tape record size must be in the range between 4KB and 256KB`

- **Cause**

  The blocking factor specified for the backup or restore operation is not within the permitted range.

- **Corrective action**

  Specify a blocking factor in the range of 4 KB to 256 KB.

NDMP error messages

Network communication error

- **Message**

  `Network communication error`

- **Cause**

  Communication to a remote tape in an NDMP three-way connection has failed.

- **Corrective action**

  Check the network connection to the remote mover.

Message from Read Socket: error_string

- **Message**

```
Message from Read Socket: error_string
```

- **Cause**

  Restore communication from the remote tape in NDMP 3-way connection has errors.

- **Corrective action**

  Check the network connection to the remote mover.

Message from Write Dirnet: error_string

- **Message**

  ```
  Message from Write Dirnet: error_string
  ```

- **Cause**

  Backup communication to a remote tape in an NDMP three-way connection has an error.

- **Corrective action**

  Check the network connection to the remote mover.

Read Socket received EOF

- **Message**

  ```
  Read Socket received EOF
  ```

- **Cause**

  Attempt to communicate with a remote tape in an NDMP three-way connection has reached the End Of File mark. You might be attempting a three-way restore from a backup image with a larger block size.

- **Corrective action**

  Specify the correct block size and retry the restore operation.

ndmpd invalid version number: version_number ``

- **Message**

  ```
  ndmpd invalid version number: version_number
  ```

- **Cause**

  The NDMP version specified is not supported by the storage system.

- **Corrective action**

  Specify NDMP version 4.

ndmpd session session_ID not active

- **Message**

  `ndmpd session session_ID not active`

- **Cause**

  The NDMP session might not exist.

- **Corrective action**

  Use the `ndmpd status` command to view the active NDMP sessions.

Could not obtain vol ref for Volume volume_name

- **Message**

  `Could not obtain vol ref for Volume vol_name`

- **Cause**

  The volume reference could not be obtained because the volume might be in use by other operations.

- **Corrective action**

  Retry the operation later.

Data connection type ["NDMP4_ADDR_TCP"|"NDMP4_ADDR_TCP_IPv6"] not supported for ["IPv6"|"IPv4"] control connections

- **Message**

  ```
  Data connection type ["NDMP4_ADDR_TCP"|"NDMP4_ADDR_TCP_IPv6"] not supported
  for ["IPv6"|"IPv4"] control connections
  ```

- **Cause**

  In node-scoped NDMP mode, the NDMP data connection established must be of the same network address type (IPv4 or IPv6) as the NDMP control connection.

- **Corrective action**

  Contact your backup application vendor.

DATA LISTEN: CAB data connection prepare precondition error

- **Message**

  `DATA LISTEN: CAB data connection prepare precondition error`

- **Cause**

  NDMP data listen fails when the backup application has negotiated the CAB extension with the NDMP server and there is a mismatch in the specified NDMP data connection address type between the NDMP_CAB_DATA_CONN_PREPARE and the NDMP_DATA_LISTEN messages.

- **Corrective action**

  Contact your backup application vendor.

DATA CONNECT: CAB data connection prepare precondition error

- **Message**

  `DATA CONNECT: CAB data connection prepare precondition error`

- **Cause**

  NDMP data connect fails when the backup application has negotiated the CAB extension with the NDMP server and there is a mismatch in the specified NDMP data connection address type between the NDMP_CAB_DATA_CONN_PREPARE and the NDMP_DATA_CONNECT messages.

- **Corrective action**

  Contact your backup application vendor.

Error:show failed: Cannot get password for user '<username>'

- **Message**

  `Error: show failed: Cannot get password for user '<username>'`

- **Cause**

  Incomplete user account configuration for NDMP

- **Corrective action**

  Ensure that the user account is associated with the SSH access method and the authentication method is user password.

Dump error messages

Destination volume is read-only

- **Message**

  `Destination volume is read-only`

- **Cause**

  The path to which the restore operation is attempted to is read-only.

- **Corrective action**

  Try restoring the data to a different location.

Destination qtree is read-only

- **Message**

  `Destination qtree is read-only`

- **Cause**

  The qtree to which the restore is attempted to is read-only.

- **Corrective action**

  Try restoring the data to a different location.

Dumps temporarily disabled on volume, try again

- **Message**

  `Dumps temporarily disabled on volume, try again`

- **Cause**

  NDMP dump backup is attempted on a SnapMirror destination volume that is part of either a `snapmirror break` or a `snapmirror resync` operation.

- **Corrective action**

  Wait for the `snapmirror break` or `snapmirror resync` operation to finish and then perform the dump operation.

  > Whenever the state of a SnapMirror destination volume changes from read/write to read-only or from read-only to read/write, you must perform a baseline backup.

Related information

- snapmirror break
- snapmirror resync

NFS labels not recognized

- **Message**

  `Error: Aborting: dump encountered NFS security labels in the file system`

- **Cause**

  NFS security labels are supported Beginning with ONTAP 9.9.1 when NFSv4.2 is enabled. However, NFS security labels are not currently recognized by the dump engine. If it encounters any NFS security labels on the files, directories, or any special files in any format of dump, the dump fails.

- **Corrective action**

  Verify that no files or directories have NFS security labels.

No files were created

- **Message**

  `No files were created`

- **Cause**

  A directory DAR was attempted without enabling the enhanced DAR functionality.

- **Corrective action**

  Enable the enhanced DAR functionality and retry the DAR.

Restore of the file <file name> failed

- **Message**

  `Restore of the file file name failed`

- **Cause**

  When a DAR (Direct Access Recovery) of a file whose file name is the same as that of a LUN on the destination volume is performed, then the DAR fails.

- **Corrective action**

  Retry DAR of the file.

Truncation failed for src inode <inode number>…

- **Message**

  `Truncation failed for src inode <inode number>. Error <error number>. Skipping inode.`

- **Cause**

  Inode of a file is deleted when the file is being restored.

- **Corrective action**

  Wait for the restore operation on a volume to complete before using that volume.

Unable to lock a snapshot needed by dump

- **Message**

  `Unable to lock a snapshot needed by dump`

- **Cause**

  The snapshot specified for the backup is not available.

* **Corrective action**

  Retry the backup with a different snapshot.

  Use the `snap list` command to see the list of available snapshots.

  Learn more about `snap list` in the ONTAP command reference.

Unable to locate bitmap files

* **Message**

  `Unable to locate bitmap files`

* **Cause**

  The bitmap files required for the backup operation might have been deleted. In this case, the backup cannot be restarted.

* **Corrective action**

  Perform the backup again.

Volume is temporarily in a transitional state

* **Message**

  `Volume is temporarily in a transitional state`

* **Cause**

  The volume being backed up is temporarily in an unmounted state.

* **Corrective action**

  Wait for some time and perform the backup again.

SMTape error messages

Chunks out of order

* **Message**

  `Chunks out of order`

* **Cause**

  The backup tapes are not being restored in the correct sequence.

* **Corrective action**

  Retry the restore operation and load the tapes in the correct sequence.

Chunk format not supported

- **Message**

  `Chunk format not supported`

- **Cause**

  The backup image is not of SMTape.

- **Corrective action**

  If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.

Failed to allocate memory

- **Message**

  `Failed to allocate memory`

- **Cause**

  The system has run out of memory.

- **Corrective action**

  Retry the job later when the system is not too busy.

Failed to get data buffer

- **Message**

  `Failed to get data buffer`

- **Cause**

  The storage system ran out of buffers.

- **Corrective action**

  Wait for some storage system operations to finish and then retry the job.

Failed to find snapshot

- **Message**

  `Failed to find snapshot`

- **Cause**

  The snapshot specified for the backup is unavailable.

- **Corrective action**

Check if the specified snapshot is available. If not, retry with the correct snapshot.

Failed to create snapshot

- **Message**

  `Failed to create snapshot`

- **Cause**

  The volume already contains the maximum number of snapshots.

- **Corrective action**

  Delete some snapshots and then retry the backup operation.

Failed to lock snapshot

- **Message**

  `Failed to lock snapshot`

- **Cause**

  The snapshot is either in use or has been deleted.

- **Corrective action**

  If the snapshot is in use by another operation, wait for that operation to finish and then retry the backup. If the snapshot has been deleted, you cannot perform the backup.

Failed to delete snapshot

- **Message**

  `Failed to delete snapshot`

- **Cause**

  The auto snapshot could not be deleted because it is in use by other operations.

- **Corrective action**

  Use the `snap` command to determine the status of the snapshot. If the snapshot is not required, delete it manually.

Failed to get latest snapshot

- **Message**

  `Failed to get latest snapshot`

- **Cause**

The latest snapshot might not exist because the volume is being initialized by SnapMirror.

- **Corrective action**

  Retry after initialization is complete.

Failed to load new tape

- **Message**

  `Failed to load new tape`

- **Cause**

  Error in tape drive or media.

- **Corrective action**

  Replace the tape and retry the operation.

Failed to initialize tape

- **Message**

  `Failed to initialize tape`

- **Cause**

  You might get this error message for one of the following reasons:

  - The backup image is not of SMTape.
  - The tape blocking factor specified is incorrect.
  - The tape is corrupt or damaged.
  - The wrong tape is loaded for restore.

- **Corrective action**
  - If the backup image is not of SMTape, retry the operation with a tape that has SMTape backup.
  - If the blocking factor is incorrect, specify the correct blocking factor and retry the operation.
  - If the tape is corrupt, you cannot perform the restore operation.
  - If the wrong tape is loaded, retry the operation with the correct tape.

Failed to initialize restore stream

- **Message**

  `Failed to initialize restore stream`

- **Cause**

  You might get this error message for one of the following reasons:

  - The backup image is not of SMTape.

    - The tape blocking factor specified is incorrect.
    - The tape is corrupt or damaged.
    - The wrong tape is loaded for restore.
- **Corrective action**
    - If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.
    - If the blocking factor is incorrect, specify the correct blocking factor and retry the operation.
    - If the tape is corrupt, you cannot perform the restore operation.
    - If the wrong tape is loaded, retry the operation with the correct tape.

Failed to read backup image

- **Message**

  `Failed to read backup image`

- **Cause**

  The tape is corrupt.

- **Corrective action**

  If the tape is corrupt, you cannot perform the restore operation.

Image header missing or corrupted

- **Message**

  `Image header missing or corrupted`

- **Cause**

  The tape does not contain a valid SMTape backup.

- **Corrective action**

  Retry with a tape containing a valid backup.

Internal assertion

- **Message**

  `Internal assertion`

- **Cause**

  There is an internal SMTape error.

- **Corrective action**

  Report the error and send the `etc/log/backup` file to technical support.

Invalid backup image magic number

- **Message**

  `Invalid backup image magic number`

- **Cause**

  The backup image is not of SMTape.

- **Corrective action**

  If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.

Invalid backup image checksum

- **Message**

  `Invalid backup image checksum`

- **Cause**

  The tape is corrupt.

- **Corrective action**

  If the tape is corrupt, you cannot perform the restore operation.

Invalid input tape

- **Message**

  `Invalid input tape`

- **Cause**

  The signature of the backup image is not valid in the tape header. The tape has corrupted data or does not contain a valid backup image.

- **Corrective action**

  Retry the restore job with a valid backup image.

Invalid volume path

- **Message**

  `Invalid volume path`

- **Cause**

  The specified volume for the backup or restore operation is not found.

- **Corrective action**

Retry the job with a valid volume path and volume name.

Mismatch in backup set ID

- **Message**

  `Mismatch in backup set ID`

- **Cause**

  The tape loaded during a tape change is not a part of the backup set.

- **Corrective action**

  Load the correct tape and retry the job.

Mismatch in backup time stamp

- **Message**

  `Mismatch in backup time stamp`

- **Cause**

  The tape loaded during a tape change is not a part of the backup set.

- **Corrective action**

  Use the `smtape restore -h` command to verify the header information of a tape.

Job aborted due to shutdown

- **Message**

  `Job aborted due to shutdown`

- **Cause**

  The storage system is being rebooted.

- **Corrective action**

  Retry the job after the storage system reboots.

Job aborted due to snapshot autodelete

- **Message**

  `Job aborted due to snapshot autodelete`

- **Cause**

  The volume does not have enough space and has triggered the automatic deletion of snapshots.

* **Corrective action**

  Free up space in the volume and retry the job.

Tape is currently in use by other operations

* **Message**

  `Tape is currently in use by other operations`

* **Cause**

  The tape drive is in use by another job.

* **Corrective action**

  Retry the backup after the currently active job is finished.

Tapes out of order

* **Message**

  `Tapes out of order`

* **Cause**

  The first tape of the tape sequence for the restore operation does not have the image header.

* **Corrective action**

  Load the tape with the image header and retry the job.

Transfer failed (Aborted due to MetroCluster operation)

* **Message**

  `Transfer failed (Aborted due to MetroCluster operation)`

* **Cause**

  The SMTape operation is aborted because of a switchover or switchback operation.

* **Corrective action**

  Perform the SMTape operation after the switchover or switchback operation finishes.

Transfer failed (ARL initiated abort)

* **Message**

  `Transfer failed (ARL initiated abort)`

* **Cause**

While an SMTape operation is in progress if an aggregate relocation is initiated, then the SMTape operation is aborted.

- **Corrective action**

  Perform the SMTape operation after the aggregate relocation operation finishes.

Transfer failed (CFO initiated abort)

- **Message**

  `Transfer failed (CFO initiated abort)`

- **Cause**

  The SMTape operation is aborted because of a storage failover (takeover and giveback) operation of a CFO aggregate.

- **Corrective action**

  Perform the SMTape operation after the storage failover of the CFO aggregate finishes.

Transfer failed (SFO initiated abort)

- **Message**

  `Transfer failed (SFO initiated abort)`

- **Cause**

  The SMTape operation is aborted because of a storage failover (takeover and giveback) operation.

- **Corrective action**

  Perform the SMTape operation after the storage failover (takeover and giveback) operation finishes.

Underlying aggregate under migration

- **Message**

  `Underlying aggregate under migration`

- **Cause**

  If an SMTape operation is initiated on an aggregate that is under migration (storage failover or aggregate relocation), then the SMTape operation fails.

- **Corrective action**

  Perform the SMTape operation after the aggregate migration finishes.

Volume is currently under migration

- **Message**

  `Volume is currently under migration`

- **Cause**

  Volume migration and SMTape backup cannot run simultaneously.

- **Corrective action**

  Retry the backup job after the volume migration is complete.

Volume offline

- **Message**

  `Volume offline`

- **Cause**

  The volume being backed up is offline.

- **Corrective action**

  Bring the volume online and retry the backup.

Volume not restricted

- **Message**

  `Volume not restricted`

- **Cause**

  The destination volume to which data is being restored is not restricted.

- **Corrective action**

  Restrict the volume and retry the restore operation.

NDMP configuration

Learn about ONTAP NDMP configuration

You can quickly configure an ONTAP 9 cluster to use the Network Data Management Protocol (NDMP) to back up data directly to tape using a third-party backup application.

If the backup application supports Cluster Aware Backup (CAB), you can configure NDMP as *SVM-scoped* or *node-scoped*:

- SVM-scoped at the cluster (admin SVM) level enables you to back up all volumes hosted across different nodes of the cluster. SVM-scoped NDMP is recommended where possible.

- Node-scoped NDMP enables you to back up all the volumes hosted on that node.

If the backup application does not support CAB, you must use node-scoped NDMP.

SVM-scoped and node-scoped NDMP are mutually exclusive; they cannot be configured on the same cluster.

> Node-scoped NDMP is deprecated in ONTAP 9.

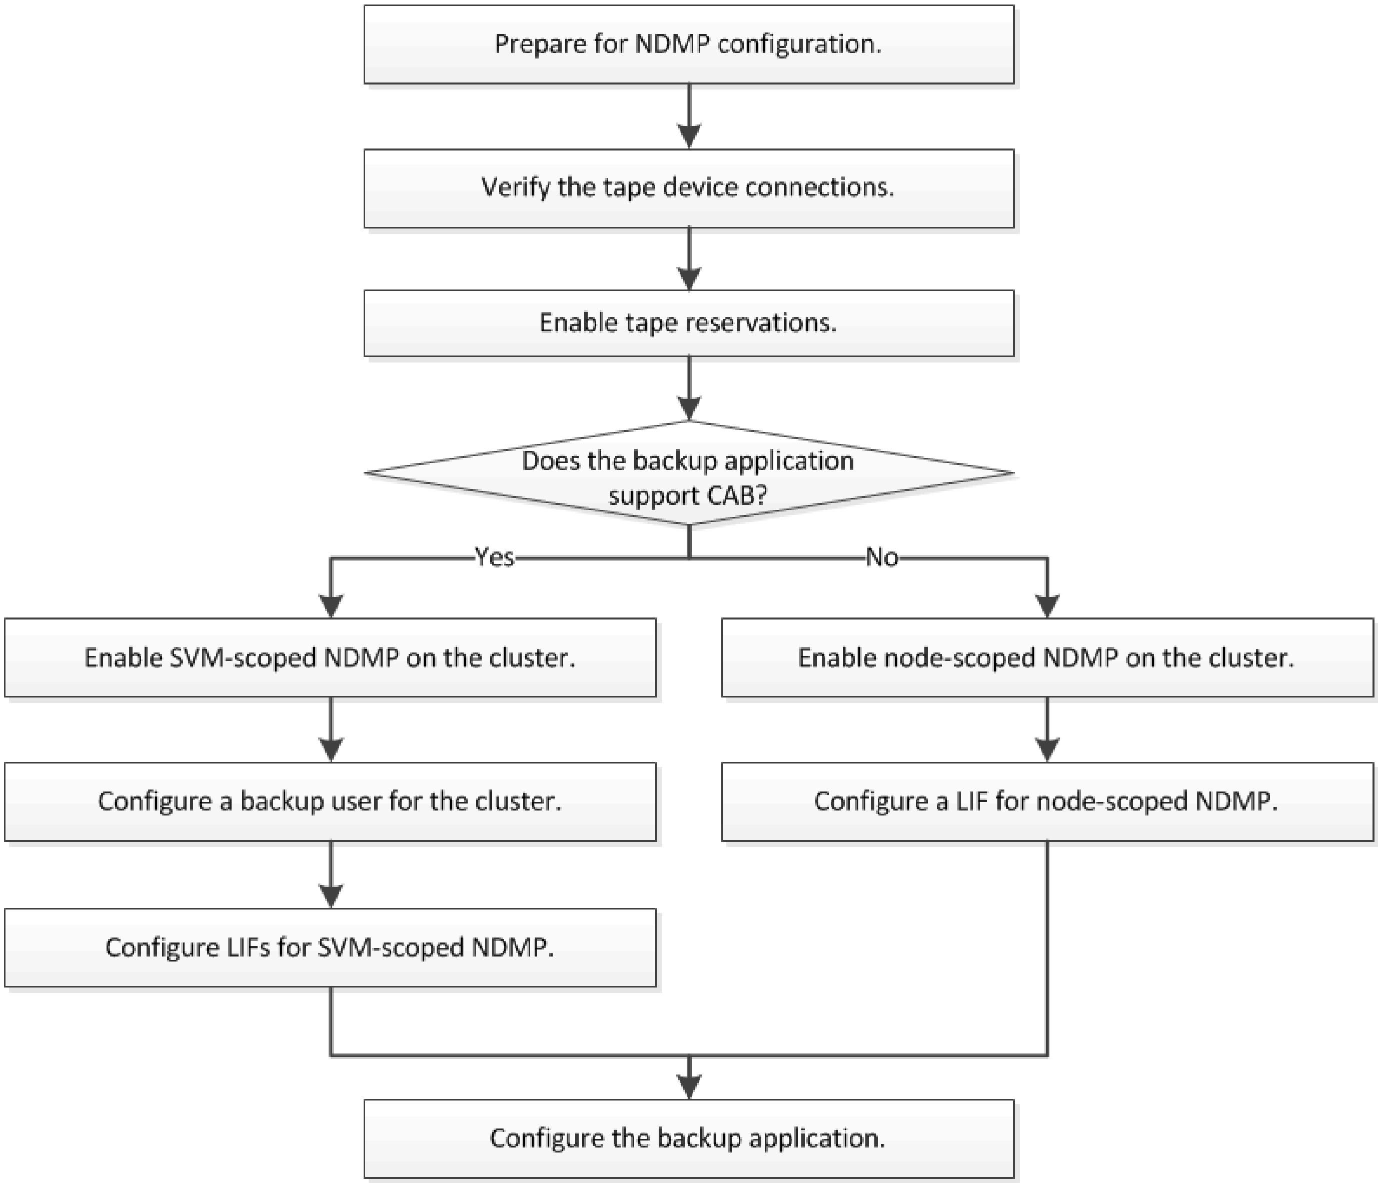
Learn more about Cluster Aware Backup (CAB).

Before configuring NDMP, verify the following:

- You have a third-party backup application (also called a Data Management Application or DMA).
- You are a cluster administrator.
- Tape devices and an optional media server are installed.
- Tape devices are connected to the cluster through a Fibre Channel (FC) switch or locally attached.
- At least one tape device has a logical unit number (LUN) of 0.

Learn about ONTAP NDMP configuration workflow

Setting up tape backup over NDMP involves preparing for NDMP configuration, verifying the tape device connections, enabling tape reservations, configuring NDMP at the SVM or node level, enabling NDMP on the cluster, configuring a backup user, configuring LIFs, and configuring the backup application.



Prepare ONTAP NDMP configurations

Before you configure tape backup access over Network Data Management Protocol (NDMP), you must verify that the planned configuration is supported, verify that your tape drives are listed as qualified drives on each node, verify that all nodes have intercluster LIFs, and identify whether the backup application supports the Cluster Aware Backup (CAB) extension.

Steps

1. Refer to your backup application provider's compatibility matrix for ONTAP support (NetApp does not qualify third-party backup applications with ONTAP or NDMP).

   You should verify that the following NetApp components are compatible:

   ◦ The version of ONTAP 9 that is running on the cluster.

   ◦ The backup application vendor and version: for example, Veritas NetBackup 8.2 or CommVault.

◦ The tape devices details, such as the manufacturer, model, and interface of the tape drives: for example, IBM Ultrium 8 or HPe StoreEver Ultrium 30750 LTO-8.
◦ The platforms of the nodes in the cluster: for example, FAS8700 or A400.

> You can find legacy ONTAP compatibility support matrices for backup applications in the NetApp Interoperability Matrix Tool.

2. Verify that your tape drives are listed as qualified drives in each node's built-in tape configuration file:
   a. On the command line-interface, view the built-in tape configuration file by using the `storage tape show-supported-status` command.

```
cluster1::> storage tape show-supported-status

Node: cluster1-1
                                Is
Tape Drives                     Supported  Support Status
------------------------------  ---------
-------------------------------
Certance Ultrium 2              true       Dynamically Qualified
Certance Ultrium 3              true       Dynamically Qualified
Digital DLT2000                 true       Qualified
```

   b. Compare your tape drives to the list of qualified drives in the output.

   > The names of the tape devices in the output might vary slightly from the names on the device label or in the Interoperability Matrix. For example, Digital DLT2000 can also be known as DLT2k. You can ignore these minor naming differences.

   c. If a device is not listed as qualified in the output even though the device is qualified according to the Interoperability Matrix, download and install an updated configuration file for the device using the instructions on the NetApp Support Site.

   NetApp Downloads: Tape Device Configuration Files

   A qualified device might not be listed in the built-in tape configuration file if the tape device was qualified after the node was shipped.

3. Verify that every node in the cluster has an intercluster LIF:
   a. View the intercluster LIFs on the nodes by using the `network interface show -role intercluster` command.

```
cluster1::> network interface show -role intercluster

              Logical    Status     Network            Current
Current Is
Vserver      Interface  Admin/Oper Address/Mask       Node
Port     Home
----------- ---------- ---------- ------------------ -------------
------- ----
cluster1     IC1        up/up      192.0.2.65/24      cluster1-1
e0a      true
```

Learn more about `network interface show` in the ONTAP command reference.

b. If an intercluster LIF does not exist on any node, create an intercluster LIF by using the `network interface create` command.

```
cluster1::> network interface create -vserver cluster1 -lif IC2 -role
intercluster
-home-node cluster1-2 -home-port e0b -address 192.0.2.68 -netmask
255.255.255.0
-status-admin up -failover-policy local-only -firewall-policy
intercluster

cluster1::> network interface show -role intercluster

              Logical    Status     Network            Current
Current Is
Vserver      Interface  Admin/Oper Address/Mask       Node
Port     Home

```

Learn more about `network interface create` in the ONTAP command reference.

Network management

4. Identify whether the backup application supports Cluster Aware Backup (CAB) by using the documentation provided with the backup application.

   CAB support is a key factor in determining the type of backup you can perform.

Verify ONTAP NDMP tape device connections

You must ensure that all drives and media changers are visible in ONTAP as devices.

Steps

1. View information about all drives and media changers by using the `storage tape show` command.

```
cluster1::> storage tape show

Node: cluster1-01
Device ID              Device Type     Description
Status
---------------------- --------------  ------------------------------
--------
sw4:10.11              tape drive      HP LTO-3
normal
0b.125L1               media changer   HP MSL G3 Series
normal
0d.4                   tape drive      IBM LTO 5 ULT3580
normal
0d.4L1                 media changer   IBM 3573-TL
normal
...
```

2. If a tape drive is not displayed, troubleshoot the problem.
3. If a media changer is not displayed, view information about media changers by using the `storage tape show-media-changer` command, and then troubleshoot the problem.

```
cluster1::> storage tape show-media-changer

Media Changer: sw4:10.11L1
  Description: PX70-TL
         WWNN: 2:00a:000e11:10b919
         WWPN: 2:00b:000e11:10b919
Serial Number: 00FRU7800000_LL1

       Errors: -

Paths:
Node                       Initiator  Alias    Device State
Status
------------------------   ---------  -------  ------------------------

```

Enable tape reservations for ONTAP NDMP backup operations

You must ensure that tape drives are reserved for use by backup applications for NDMP backup operations.

About this task

The reservation settings vary in different backup applications, and these settings must match the backup application and the nodes or servers using the same drives. See the vendor documentation of the backup application for the correct reservation settings.

Steps

1. Enable reservations by using the `options -option-name tape.reservations -option-value persistent` command.

   The following command enables reservations with the `persistent` value:

   ```
   cluster1::> options -option-name tape.reservations -option-value
   persistent
   2 entries were modified.
   ```

2. Verify that reservations are enabled on all nodes by using the `options tape.reservations` command, and then review the output.

```
cluster1::> options tape.reservations

cluster1-1
    tape.reservations                  persistent

cluster1-2
    tape.reservations                  persistent
2 entries were displayed.
```

Configure SVM-scoped NDMP

Enable SVM-scoped NDMP on the ONTAP cluster

If the DMA supports the Cluster Aware Backup (CAB) extension, you can back up all the volumes hosted across different nodes in a cluster by enabling SVM-scoped NDMP, enabling NDMP service on the cluster (admin SVM), and configuring LIFs for data and control connection.

Before you begin

The CAB extension must be supported by the DMA.

About this task

Turning off node-scoped NDMP mode enables SVM-scoped NDMP mode on the cluster.

Steps

1. Enable SVM-scoped NDMP mode:

   ```
   cluster1::> system services ndmp node-scope-mode off
   ```

   SVM-scoped NDMP mode is enabled.

2. Enable NDMP service on the admin SVM:

   ```
   cluster1::> vserver services ndmp on -vserver cluster1
   ```

   The authentication type is set to `challenge` by default and plaintext authentication is disabled.

   > For secure communication, you should keep plaintext authentication disabled.

3. Verify that NDMP service is enabled:

   ```
   cluster1::> vserver services ndmp show
   ```

```
Vserver        Enabled   Authentication type
-------------- --------- --------------------
cluster1       true      challenge
vs1            false     challenge
```

Enable backup users for ONTAP NDMP authentication

To authenticate SVM-scoped NDMP from the backup application, there must be an administrative user with sufficient privileges and an NDMP password.

About this task

You must generate an NDMP password for backup admin users. You can enable backup admin users at the cluster or SVM level, and if necessary, you can create a new user. By default, the users with the following roles can authenticate for NDMP backup:

- Cluster-wide: `admin` or `backup`
- Individual SVMs: `vsadmin` or `vsadmin-backup`

If you are using an NIS or LDAP user, the user must exist on the respective server. You cannot use an Active Directory user.

Steps

1. Display the current admin users and permissions:

   ```
   security login show
   ```

   Learn more about `security login show` in the ONTAP command reference.

2. If needed, create a new NDMP backup user with the `security login create` command and the appropriate role for cluster-wide or individual SVM privileges.

   You can specify a local backup user name or an NIS or LDAP user name for the `-user-or-group-name` parameter.

   The following command creates the backup user `backup_admin1` with the `backup` role for the entire cluster:

   ```
   cluster1::> security login create -user-or-group-name backup_admin1
   -application ssh -authmethod password -role backup
   ```

   The following command creates the backup user `vsbackup_admin1` with the `vsadmin-backup` role for an individual SVM:

   ```
   cluster1::> security login create -user-or-group-name vsbackup_admin1
   -application ssh -authmethod password -role vsadmin-backup
   ```

   Enter a password for the new user and confirm.

   Learn more about `security login create` in the ONTAP command reference.

3. Generate a password for the admin SVM by using the `vserver services ndmp generate password` command.

   The generated password must be used to authenticate the NDMP connection by the backup application.

   ```
   cluster1::> vserver services ndmp generate-password -vserver cluster1
   -user backup_admin1

    Vserver: cluster1
       User: backup_admin1
   Password: qG5CqQHYxw7tE57g
   ```

Configure ONTAP LIFs for SVM-scoped NDMP

You must identify the LIFs that will be used for establishing a data connection between the data and tape resources, and for control connection between the admin SVM and the backup application. After identifying the LIFs, you must verify the service and failover policies are set.

> Beginning with ONTAP 9.10.1, firewall policies are deprecated and wholly replaced with LIF service policies. For more information, see Manage supported traffic.

ONTAP 9.10.1 or later

Steps

1. Identify the intercluster LIF hosted on the nodes by using the `network interface show` command with the `-service-policy` parameter.

   ```
   network interface show -service-policy default-intercluster
   ```

   Learn more about `network interface show` in the ONTAP command reference.

2. Identify the management LIF hosted on the nodes by using the `network interface show` command with the `-service-policy` parameter.

   ```
   network interface show -service-policy default-management
   ```

3. Ensure that the intercluster LIF includes the `backup-ndmp-control` service:

   ```
   network interface service-policy show
   ```

   Learn more about `network interface service-policy show` in the ONTAP command reference.

4. Ensure that the failover policy is set appropriately for all the LIFs:

   a. Verify that the failover policy for the cluster-management LIF is set to `broadcast-domain-wide`, and the policy for the intercluster and node-management LIFs is set to `local-only` by using the `network interface show -failover` command.

      The following command displays the failover policy for the cluster-management, intercluster, and node-management LIFs:

```
cluster1::> network interface show -failover

           Logical          Home              Failover     Failover
Vserver    Interface        Node:Port         Policy       Group
--------   ---------------  ---------------   -----------  ---------
cluster    cluster1_clus1   cluster1-1:e0a    local-only   cluster
                                                        Failover
Targets:
                                                        .......
cluster1   cluster_mgmt     cluster1-1:e0m    broadcast-   Default
                                            domain-wide
                                                        Failover
Targets:
                                                        .......
           IC1              cluster1-1:e0a    local-only   Default
                                                        Failover
Targets:
           IC2              cluster1-1:e0b    local-only   Default
                                                        Failover
Targets:
                                                        .......
cluster1-1 c1-1_mgmt1       cluster1-1:e0m    local-only   Default
                                                        Failover
Targets:
                                                        ......
cluster1-2 c1-2_mgmt1       cluster1-2:e0m    local-only   Default
                                                        Failover
Targets:
                                                        ......
```

b. If the failover policies are not set appropriately, modify the failover policy by using the `network interface modify` command with the `-failover-policy` parameter.

```
cluster1::> network interface modify -vserver cluster1 -lif IC1
-failover-policy local-only
```

Learn more about `network interface modify` in the ONTAP command reference.

5. Specify the LIFs that are required for data connection by using the `vserver services ndmp modify` command with the `preferred-interface-role` parameter.

```
cluster1::> vserver services ndmp modify -vserver cluster1
-preferred-interface-role intercluster,cluster-mgmt,node-mgmt
```

6. Verify that the preferred interface role is set for the cluster by using the `vserver services ndmp show` command.

```
cluster1::> vserver services ndmp show -vserver cluster1

                Vserver: cluster1
                NDMP Version: 4
                .......
                .......
Preferred Interface Role: intercluster, cluster-mgmt, node-mgmt
```

ONTAP 9.9 or earlier

Steps

1. Identify the intercluster, cluster-management, and node-management LIFs by using the `network interface show` command with the `-role` parameter.

   The following command displays the intercluster LIFs:

```
cluster1::> network interface show -role intercluster

            Logical      Status     Network            Current
Current Is
Vserver     Interface    Admin/Oper Address/Mask       Node
Port    Home
----------- ----------   ---------- ------------------ -------------
------- ----
cluster1    IC1          up/up      192.0.2.65/24      cluster1-1
e0a     true
cluster1    IC2          up/up      192.0.2.68/24      cluster1-2
e0b     true
```

   The following command displays the cluster-management LIF:

```
cluster1::> network interface show -role cluster-mgmt

            Logical       Status     Network            Current
Current Is
Vserver     Interface     Admin/Oper Address/Mask       Node
Port    Home
----------- ----------    ---------- ------------------ -----------
------- ----
cluster1    cluster_mgmt  up/up      192.0.2.60/24      cluster1-2
e0M     true
```

The following command displays the node-management LIFs:

```
cluster1::> network interface show -role node-mgmt

             Logical            Status     Network         Current
Current Is
Vserver      Interface          Admin/Oper Address/Mask    Node
Port    Home
----------- ----------          ---------- ---------------
------------  ------  ------
cluster1     cluster1-1_mgmt1   up/up      192.0.2.69/24   cluster1-1
e0M     true
             cluster1-2_mgmt1   up/up      192.0.2.70/24   cluster1-2
e0M     true
```

Learn more about `network interface show` in the ONTAP command reference.

2. Ensure that the firewall policy is enabled for NDMP on the intercluster, cluster-management (`cluster-mgmt`), and node-management (`node-mgmt`) LIFs:

   a. Verify that the firewall policy is enabled for NDMP by using the `system services firewall policy show` command.

      The following command displays the firewall policy for the cluster-management LIF:

```
cluster1::> system services firewall policy show -policy cluster

Vserver      Policy       Service    Allowed
-------      ------------ ---------- -----------------
cluster      cluster      dns        0.0.0.0/0
                          http       0.0.0.0/0
                          https      0.0.0.0/0
                          ndmp       0.0.0.0/0
                          ndmps      0.0.0.0/0
                          ntp        0.0.0.0/0
                          rsh        0.0.0.0/0
                          snmp       0.0.0.0/0
                          ssh        0.0.0.0/0
                          telnet     0.0.0.0/0
10 entries were displayed.
```

      The following command displays the firewall policy for the intercluster LIF:

```
cluster1::> system services firewall policy show -policy
intercluster

Vserver     Policy       Service    Allowed
-------     ------------ ---------- -------------------
cluster1    intercluster dns        -
                         http       -
                         https      -
                         ndmp       0.0.0.0/0, ::/0
                         ndmps      -
                         ntp        -
                         rsh        -
                         ssh        -
                         telnet     -
9 entries were displayed.
```

The following command displays the firewall policy for the node-management LIF:

```
cluster1::> system services firewall policy show -policy mgmt

Vserver     Policy       Service    Allowed
-------     ------------ ---------- -------------------
cluster1-1  mgmt         dns        0.0.0.0/0, ::/0
                         http       0.0.0.0/0, ::/0
                         https      0.0.0.0/0, ::/0
                         ndmp       0.0.0.0/0, ::/0
                         ndmps      0.0.0.0/0, ::/0
                         ntp        0.0.0.0/0, ::/0
                         rsh        -
                         snmp       0.0.0.0/0, ::/0
                         ssh        0.0.0.0/0, ::/0
                         telnet     -
10 entries were displayed.
```

b. If the firewall policy is not enabled, enable the firewall policy by using the `system services firewall policy modify` command with the `-service` parameter.

The following command enables firewall policy for the intercluster LIF:

```
cluster1::> system services firewall policy modify -vserver
cluster1 -policy intercluster -service ndmp 0.0.0.0/0
```

3. Ensure that the failover policy is set appropriately for all the LIFs:

a. Verify that the failover policy for the cluster-management LIF is set to `broadcast-domain-wide`, and the policy for the intercluster and node-management LIFs is set to `local-only` by using the `network interface show -failover` command.

The following command displays the failover policy for the cluster-management, intercluster, and node-management LIFs:

```
cluster1::> network interface show -failover

           Logical            Home              Failover
Failover
Vserver    Interface          Node:Port         Policy
Group
---------- -----------------  -----------------
--------------------  --------
cluster    cluster1_clus1     cluster1-1:e0a    local-only
cluster
                                                     Failover
Targets:
                                                     .......

cluster1   cluster_mgmt       cluster1-1:e0m    broadcast-domain-
wide Default
                                                     Failover
Targets:
                                                     .......
           IC1                 cluster1-1:e0a    local-only
Default
                                                     Failover
Targets:
           IC2                 cluster1-1:e0b    local-only
Default
                                                     Failover
Targets:
                                                     .......
cluster1-1 cluster1-1_mgmt1   cluster1-1:e0m    local-only
Default
                                                     Failover
Targets:
                                                     ......
cluster1-2 cluster1-2_mgmt1   cluster1-2:e0m    local-only
Default
                                                     Failover
Targets:
                                                     ......
```

b. If the failover policies are not set appropriately, modify the failover policy by using the `network interface modify` command with the `-failover-policy` parameter.

```
cluster1::> network interface modify -vserver cluster1 -lif IC1
-failover-policy local-only
```

Learn more about `network interface modify` in the ONTAP command reference.

4. Specify the LIFs that are required for data connection by using the `vserver services ndmp modify` command with the `preferred-interface-role` parameter.

```
cluster1::> vserver services ndmp modify -vserver cluster1
-preferred-interface-role intercluster,cluster-mgmt,node-mgmt
```

5. Verify that the preferred interface role is set for the cluster by using the `vserver services ndmp show` command.

```
cluster1::> vserver services ndmp show -vserver cluster1

                             Vserver: cluster1
                        NDMP Version: 4
                        .......
                        .......
            Preferred Interface Role: intercluster, cluster-mgmt,
node-mgmt
```

Configure node-scoped NDMP

Enable node-scoped NDMP on the ONTAP cluster

You can back up volumes hosted on a single node by enabling node-scoped NDMP, enabling the NDMP service, and configuring a LIF for data and control connection. This can be done for all nodes of the cluster.

Node-scoped NDMP is deprecated in ONTAP 9.

About this task

When using NDMP in node-scope mode, authentication must be configured on a per-node basis. For more information, see the Knowledge Base article "How to configure NDMP authentication in the ‘node-scope’ mode".

Steps

1. Enable node-scoped NDMP mode:

```
cluster1::> system services ndmp node-scope-mode on
```

NDMP node-scope-mode is enabled.

2. Enable NDMP service on all nodes in the cluster:

   Using the wildcard "*" enables NDMP service on all nodes at the same time.

   You must specify a password for authentication of the NDMP connection by the backup application.

   ```
   cluster1::> system services ndmp on -node *
   ```

   ```
   Please enter password:
   Confirm password:
   2 entries were modified.
   ```

3. Disable the `-clear-text` option for secure communication of the NDMP password:

   Using the wildcard "*" disables the `-clear-text` option on all nodes at the same time.

   ```
   cluster1::> system services ndmp modify -node * -clear-text false
   ```

4. Verify that NDMP service is enabled and the `-clear-text` option is disabled:

   ```
   cluster1::> system services ndmp show
   ```

   ```
   Node                  Enabled   Clear text  User Id
   --------------------- --------- ----------- ---------
   cluster1-1            true      false        root
   cluster1-2            true      false        root
   2 entries were displayed.
   ```

Configure ONTAP LIFs for node-scoped NDMP

You must identify a LIF that will be used for establishing a data connection and control connection between the node and the backup application. After identifying the LIF, you must verify that firewall and failover policies are set for the LIF.

> Beginning with ONTAP 9.10.1, firewall policies are deprecated and wholly replaced with LIF service policies. For more information, see Manage supported traffic.

ONTAP 9.10.1 or later

Steps

1. Identify the intercluster LIF hosted on the nodes by using the `network interface show` command with the `-service-policy` parameter.

   ```
   network interface show -service-policy default-intercluster
   ```

2. Ensure that the intercluster LIF includes the `backup-ndmp-control` service:

   ```
   network interface service-policy show
   ```

3. Ensure that the failover policy is set appropriately for the intercluster LIFs:

   a. Verify that the failover policy for the intercluster LIFs is set to `local-only` by using the `network interface show -failover` command.

   ```
   cluster1::> network interface show -failover
               Logical          Home               Failover
   Failover
   Vserver     Interface        Node:Port          Policy       Group
   --------    ---------------  -----------------  ------------
   --------
   cluster1    IC1               cluster1-1:e0a    local-only
   Default
                                                        Failover
   Targets:
                                                        .......
               IC2               cluster1-2:e0b    local-only
   Default
                                                        Failover
   Targets:
                                                        .......
   cluster1-1  cluster1-1_mgmt1 cluster1-1:e0m    local-only
   Default
                                                        Failover
   Targets:
                                                        .......
   ```

   b. If the failover policy is not set appropriately, modify the failover policy by using the `network interface modify` command with the `-failover-policy` parameter.

   ```
   cluster1::> network interface modify -vserver cluster1 -lif IC1
   -failover-policy local-only
   ```

Learn more about `network interface show`, `network interface service-policy show`, and `network interface modify` in the ONTAP command reference.

ONTAP 9.9 or earlier

Steps

1. Identify the intercluster LIF hosted on the nodes by using the `network interface show` command with the `-role` parameter.

```
cluster1::> network interface show -role intercluster

            Logical    Status     Network            Current
Current Is
Vserver     Interface  Admin/Oper Address/Mask       Node
Port    Home
----------- ---------- ---------- ------------------ -------------
------- ----
cluster1    IC1        up/up      192.0.2.65/24      cluster1-1
e0a     true
cluster1    IC2        up/up      192.0.2.68/24      cluster1-2
e0b     true
```

2. Ensure that the firewall policy is enabled for NDMP on the intercluster LIFs:

   a. Verify that the firewall policy is enabled for NDMP by using the `system services firewall policy show` command.

   The following command displays the firewall policy for the intercluster LIF:

```
cluster1::> system services firewall policy show -policy
intercluster

Vserver     Policy       Service    Allowed
-------     ------------ ---------- -------------------
cluster1    intercluster dns        -
                         http       -
                         https      -
                         ndmp       0.0.0.0/0, ::/0
                         ndmps      -
                         ntp        -
                         rsh        -
                         ssh        -
                         telnet     -
9 entries were displayed.
```

   b. If the firewall policy is not enabled, enable the firewall policy by using the `system services firewall policy modify` command with the `-service` parameter.

The following command enables firewall policy for the intercluster LIF:

```
cluster1::> system services firewall policy modify -vserver
cluster1 -policy intercluster -service ndmp 0.0.0.0/0
```

3. Ensure that the failover policy is set appropriately for the intercluster LIFs:

   a. Verify that the failover policy for the intercluster LIFs is set to `local-only` by using the `network interface show -failover` command.

```
cluster1::> network interface show -failover
            Logical          Home               Failover
Failover
Vserver     Interface        Node:Port          Policy       Group
--------    ---------------  -----------------  ------------
--------
cluster1    IC1               cluster1-1:e0a     local-only
Default
                                                     Failover
Targets:
                                                     .......
            IC2               cluster1-2:e0b     local-only
Default
                                                     Failover
Targets:
                                                     .......
cluster1-1  cluster1-1_mgmt1 cluster1-1:e0m     local-only
Default
                                                     Failover
Targets:
                                                     .......
```

   b. If the failover policy is not set appropriately, modify the failover policy by using the `network interface modify` command with the `-failover-policy` parameter.

```
cluster1::> network interface modify -vserver cluster1 -lif IC1
-failover-policy local-only
```

Learn more about `network interface show` and `network interface modify` in the ONTAP command reference.

Configure backup applications for ONTAP NDMP configuration

After the cluster is configured for NDMP access, you must gather information from the cluster configuration and then configure the rest of the backup process in the backup application.

Steps

1. Gather the following information that you configured earlier in ONTAP:
   - The user name and password that the backup application requires to create the NDMP connection
   - The IP addresses of the intercluster LIFs that the backup application requires to connect to the cluster
2. In ONTAP, display the aliases that ONTAP assigned to each device by using the `storage tape alias show` command.

   The aliases are often useful in configuring the backup application.

   ```
   cluster1::> storage tape show -alias

     Device ID: 2a.0
   Device Type: tape drive
   Description: Hewlett-Packard LTO-5

   Node                           Alias     Mapping
   --------------------------- --------- ------------------------------
   stsw-3220-4a-4b-02          st2       SN[HU19497WVR]
   ...
   ```

3. In the backup application, configure the rest of the backup process by using the backup application's documentation.

After you finish

If a data mobility event occurs, such as a volume move or LIF migration, you must be prepared to reinitialize any interrupted backup operations.

Replication between NetApp Element software and ONTAP overview

You can ensure business continuity on an Element system by using SnapMirror to replicate snapshots of an Element volume to an ONTAP destination. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, and then reactivate the Element system when service is restored.

Beginning with ONTAP 9.4, you can replicate snapshots of a LUN created on an ONTAP node back to an Element system. You might have created a LUN during an outage at the Element site, or you might be using a LUN to migrate data from ONTAP to Element software.

Configure replication of NetApp Element software and ONTAP.

Event, performance, and health monitoring

Monitor cluster performance with System Manager

Monitor cluster performance using ONTAP System Manager

The topics in this section show you how to manage cluster health and performance with System Manager in ONTAP 9.7 and later releases.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to monitor your cluster performance. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

You can monitor cluster performance by viewing information about your system on the System Manager Dashboard. The Dashboard displays information about important alerts and notifications, the efficiency and capacity of storage tiers and volumes, the nodes that are available in a cluster, the status of the nodes in an HA pair, the most active applications and objects, and the performance metrics of a cluster or a node.

The Dashboard lets you determine the following information:

- **Health**: How healthy is the cluster?
- **Capacity**: What capacity is available on the cluster?
- **Performance**: How well is the cluster performing, based on latency, IOPS, and throughput?
- **Network**: How is the network configured with hosts and storage objects, such as ports, interfaces, and storage VMs?

In the Health and Capacity overviews, you can click → to view additional information and perform tasks.

In the Performance overview, you can view metrics based on the hour, the day, the week, the month, or the year.

In the Network overview, the number of each object in the network is displayed (for example, "8 NVMe/FC ports"). You can click on the numbers to view details about each network object.

Learn about view clusters on ONTAP System Manager dashboards

The System Manager dashboard offers a quick and comprehensive view of your ONTAP cluster from a single location.

Using the System Manager dashboard, you can view at-a-glance information about important alerts and notifications, the efficiency and capacity of storage tiers and volumes, the nodes that are available in a cluster, the status of the nodes in a high-availability (HA) pair, the most active applications and objects, and the performance metrics of a cluster or a node.

The dashboard includes four panels described as follows:

Health

The Health view displays information on the overall health of all discoverable nodes in your cluster.

The Health view also displays the errors and warnings at a cluster level, such as unconfigured node details, indicating the characteristics that can be modified to enhance cluster performance.

Click → to expand the Health view to obtain an overview of the cluster such as the name of the cluster, the version, the date and time of creation of the cluster, and more. You can also monitor the statistics related to the health of the nodes associated with a cluster. You can manage tags that let you group and identify resources in your environment. The Insights section helps you optimize the capacity, security compliance, and configuration of your system.

Capacity

The Capacity view displays the storage space of a cluster. You can view the total logical space used, total physical space used, and the available disk space.

You can choose to register with ActiveIQ to view historical cluster data.
Click → to expand the Capacity view to see an overview of the tiers associated with a cluster. You can view capacity information about each of the tiers: the total space, used space, and available space. Details are displayed for throughput, IOPS, and latency. Learn more about these capacity measurements in System Manager.

You can choose to add a local tier or a cloud tier using the Capacity view. For more information, refer to View the capacity of a cluster.

Network

The Network view displays the physical ports, network interfaces, and storage VMs that are part of the network.

The Network view displays the type of clients connected to the network. Each of these network-connected clients are represented by a number (for example "NVMe/FC 16"). Select the number to view specific details on each of these network elements.

Click → to see an expansive, full-page view of the network that encompasses ports, network interfaces, storage VMs, and hosts on the network.

Performance

The Performance view displays performance statistics to help to monitor the health and efficiency of your ONTAP cluster. The statistics include key cluster performance indicators such as latency, throughput, and IOPS, represented as graphs.

The Performance view displays performance statistics at different time intervals by day, hour, week, or year. You can quickly analyze cluster performance by using the various graphs and identify the characteristics that might require optimization. This quick analysis helps you decide how you might add or move workloads. You can also look at peak usage times to plan for potential changes.

The performance view displays the total performance metrics related to latency, throughput, and IOPS.

Beginning with 9.15.1, the performance view is enhanced to display graphs for read, write, other, and total performance metrics related to latency, throughput, and IOPS. Other metrics include any operations that aren’t read or write.

The performance values refresh every 3 seconds and the performance graph refreshes every 15 seconds. A graph will not display if information about cluster performance is not available.

Click ↙↗ to see a full-page view of the performance metrics by hour, day, week, month, and year. You can also download a report of the performance metrics in your local system.

Identify hot volumes and other objects in ONTAP System Manager

Accelerate your cluster performance by identifying the frequently accessed volumes (hot volumes) and data (hot objects).

> ⓘ Beginning with ONTAP 9.10.1, you can use the Activity Tracking feature in File System Analytics to monitor hot objects in a volume.

Steps

1. Click **Storage > Volumes**.
2. Filter the IOPS, latency, and throughput columns to view the frequently accessed volumes and data.

Modify QoS in ONTAP System Manager

Beginning with ONTAP 9.8, when you provision storage, Quality of Service (QoS) is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process. You can also modify QoS after your storage has been provisioned.

Steps

1. In System Manager, select **Storage** then **Volumes**.
2. Next to the volume for which you want to modify QoS, select ⋮ then **Edit**.

Monitor risks in ONTAP System Manager

Beginning with ONTAP 9.10.0, you can use System Manager to monitor the risks reported by Active IQ Digital Advisor (also known as Digital Advisor). Beginning with ONTAP 9.10.1, you can use System Manager to also acknowledge the risks.

NetApp Digital Advisor reports opportunities to reduce risk and improve the performance and efficiency of your storage environment. With System Manager, you can learn about risks reported by Digital Advisor and receive actionable intelligence that helps you administer storage and achieve higher availability, improved security, and better storage performance.

Link to your Digital Advisor account

To receive information about risks from Digital Advisor, you should first link to your Digital Advisor account from System Manager.

Steps

1. In System Manager, click **Cluster > Settings**.
2. Under **Active IQ Registration**, click **Register**.
3. Enter your credentials for Digital Advisor.
4. After your credentials are authenticated, click **Confirm to link Active IQ with System Manager**.

View the number of risks

Beginning with ONTAP 9.10.0, you can view from the dashboard in System Manager the number of risks reported by Digital Advisor.

Before you begin

You must establish a connection from System Manager to your Digital Advisor account. Refer to Link to your Digital Advisor account.

Steps

1. In System Manager, click **Dashboard**.
2. In the **Health** section, view the number of reported risks.

> ⓘ You can view more detailed information about each risk by clicking the message showing the number of risks. See View details of risks.

View details of risks

Beginning with ONTAP 9.10.0, you can view from System Manager how the risks reported by Digital Advisor are categorized by impact areas. You can also view detailed information about each reported risk, its potential impact on your system, and corrective actions you can take.

Before you begin

You must establish a connection from System Manager to your Digital Advisor account. Refer to Link to your Digital Advisor account.

Steps

1. Click **Events > All Events**.
2. In the **Overview** section, under **Active IQ Suggestions**, view the number of risks in each impact area category. The risk categories include:
   - Performance & efficiency
   - Availability & protection
   - Capacity
   - Configuration
   - Security
3. Click on the **Active IQ Suggestions** tab to view information about each risk, including the following:
   - Level of impact to your System
   - Category of the risk
   - Nodes that are affected
   - Type of mitigation needed
   - Corrective actions you can take

Acknowledge risks

Beginning with ONTAP 9.10.1, you can use System Manager to acknowledge any of the open risks.

Steps

1. In System Manager, display the list of risks by performing the procedure in View details of risks.
2. Click on the risk name of an open risk that you want to acknowledge.
3. Enter information into the following fields:
   - Reminder (date)
   - Justification
   - Comments
4. Click **Acknowledge**.

> After you acknowledge a risk, it takes a few minutes for the change to be reflected in the list of Digital Advisor suggestions.

Unacknowledge risks

Beginning with ONTAP 9.10.1, you can use System Manager to unacknowledge any risk that was previously acknowledged.

Steps

1. In System Manager, display the list of risks by performing the procedure in View details of risks.
2. Click on the risk name of an acknowledged risk that you want to unacknowledge.
3. Enter information into the following fields:
   - Justification
   - Comments
4. Click **Unacknowledge**.

> After you unacknowledge a risk, it takes a few minutes for the change to be reflected in the list of Digital Advisor suggestions.

Optimize your system with ONTAP System Manager insights

With System Manager, you can view insights that help you optimize your system.

About this task

This procedure applies to FAS, AFF, and ASA systems. If you have an ASA r2 system (ASA A1K, ASA A90, ASA A70, ASA A50, ASA A30, ASA A20, or ASA C30), follow these steps to view insights that help you optimize your system. ASA r2 systems provide a simplified ONTAP experience specific to SAN-only customers.

Beginning with ONTAP 9.11.1, you can view insights in System Manager that help you optimize the capacity, security compliance, and configuration of your system.

Blocking extensions might lead to unexpected results. Beginning with ONTAP 9.11.1, you can enable native FPolicy for storage VMs using System Manager. You might receive a System Manager Insight message recommending that you configure native FPolicy for a storage VM.

With FPolicy Native Mode, you can allow or disallow specific file extensions. System Manager recommends over 3000 disallowed file extensions that have been used in past ransomware attacks. Some of these extensions might be used by legitimate files in your environment and blocking them might lead to unexpected issues.

Therefore, it is strongly advised that you modify the list of extensions to meet the needs of your environment. Refer to How to remove a file extension from a native FPolicy configuration created by System Manager using System Manager to recreate the policy.

To learn more about native FPolicy, see Fpolicy configuration types.

Based on best practices, these insights are displayed on one page from which you can initiate immediate actions to optimize your system. For more information, see System Manager insights.

View optimization insights

Steps

1. In System Manager, click **Insights** in the left-hand navigation column.

   The **Insights** page shows groups of insights. Each group of insights might contain one or more insights. The following groups are displayed:

   - Needs your attention
   - Remediate risks
   - Optimize your storage

2. (Optional) Filter the insights that are displayed by clicking these buttons in the upper-right corner of the page:

   -  Displays the security-related insights.
   -  Displays the capacity-related insights.
   -  Displays the configuration-related insights.
   - 

     Displays all of the insights.

Respond to insights to optimize your system

In System Manager, you can respond to insights by either dismissing them, exploring different ways to remediate the problems, or initiating the process to fix the problems.

Steps

1. In System Manager, click **Insights** in the left-hand navigation column.
2. Hover over an insight to reveal the buttons to perform the following actions:
   - **Dismiss**: Remove the insight from the view. To undismiss the insight, refer to Customize the settings

for insights.

  ◦ **Explore**: Find out various ways to remediate the problem mentioned in the insight. This button appears only if there is more than one method of remediation.
  ◦ **Fix**: Initiate the process of remediating the problem mentioned in the insight. You will be asked to confirm whether you want to take the action needed to apply the fix.

> Some of these actions can be initiated from other pages in System Manager, but the **Insights** page helps you streamline your day-to-day tasks by allowing you to initiate these action from this one page.

Customize the settings for insights

You can customize which insights you will be notified about in System Manager.

Steps

1. In System Manager, click **Insights** in the left-hand navigation column.
2. In the upper-right corner of the page, click ⋮, then select **Settings**.
3. On the **Settings** page, ensure there is a check in the check boxes next to the insights you want to be notified about. If you previously dismissed an insight, you can undismiss it by ensuring a check is in its check box.
4. Click **Save**.

Export the insights as a PDF file

You can export all applicable insights as a PDF file.

Steps

1. In System Manager, click **Insights** in the left-hand navigation column.
2. In the upper-right corner of the page, click ⋮, then select **Export**.

Configure native FPolicies in ONTAP System Manager

Beginning with ONTAP 9.11.1, when you receive a System Manager Insight that suggests implementing native FPolicy, you can configure it on your storage VMs and volumes.

Before you begin

When you access System Manager Insights, under **Apply best practices**, you might receive a message saying that native FPolicy is not configured.

To learn more about FPolicy configuration types, refer to FPolicy configuration types.

Steps

1. In System Manager, click **Insights** in the left-hand navigation column.
2. Under **Apply best practices**, locate **Native FPolicy is not configured**.
3. Read the following message before taking action:

> **Blocking extensions might lead to unexpected results.** Beginning with ONTAP 9.11.1, you can enable native FPolicy for storage VMs using System Manager.
> With FPolicy Native Mode, you can allow or disallow specific file extensions. System Manager recommends over 3000 disallowed file extensions that have been used in past ransomware attacks. Some of these extensions might be used by legitimate files in your environment and blocking them might lead to unexpected issues.
>
> Therefore, it is strongly advised that you modify the list of extensions to meet the needs of your environment. Refer to How to remove a file extension from a native FPolicy configuration created by System Manager using System Manager to recreate the policy.

4. Click **Fix**.
5. Select the storage VMs to which you want to apply the native FPolicy.
6. For each storage VM, select the volumes that will receive the native FPolicy.
7. Click **Configure**.

Monitor and manage cluster performance using the CLI

Learn about ONTAP Active IQ Unified Manager performance monitoring and management

You can set up basic performance monitoring and management tasks and identify and resolve common performance issues.

You can use these procedures to monitor and manage cluster performance if the following assumptions apply to your situation:

- You want to use best practices, not explore every available option.
- You want to display system status and alerts, monitor cluster performance, and perform root-cause analysis by using Active IQ Unified Manager (formerly OnCommand Unified Manager), in addition to the ONTAP command-line interface.
- You are using the ONTAP command line interface to configure storage quality of service (QoS). QoS is also available through the following:
  - System Manager
  - ONTAP REST API
  - ONTAP tools for VMware vSphere
  - NetApp Service Level Manager (NSLM)
  - OnCommand Workflow Automation (WFA)
- You want to install Active IQ Unified Manager by using a virtual appliance, instead of a Linux or Windows-based installation.
- You're willing to use a static configuration rather than DHCP to install the software.
- You can access ONTAP commands at the advanced privilege level.
- You are a cluster administrator with the "admin" role.

Related information

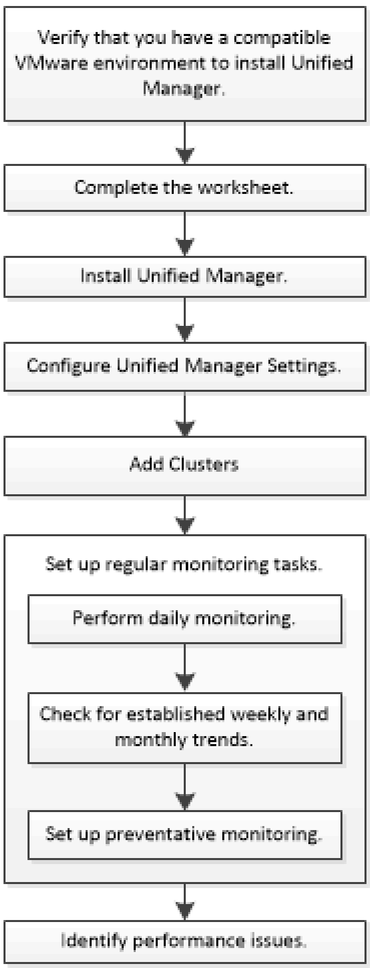
If these assumptions are not correct for your situation, you should see the following resources:

- Active IQ Unified Manager 9.8 Installation
- System administration

Monitor performance

Learn about ONTAP Active IQ Unified Manager performance monitoring and maintenance workflow

Monitoring and maintaining cluster performance involves installing Active IQ Unified Manager software, setting up basic monitoring tasks, identifying performance issues, and making adjustments as needed.



Verify VMware environment requirements for ONTAP Active IQ Unified Manager

To successfully install Active IQ Unified Manager, you must verify that your VMware environment meets the necessary requirements.

Steps

1. Verify that your VMware infrastructure meets the sizing requirements for the installation of Unified Manager.
2. Go to the Interoperability Matrix to verify that you have a supported combination of the following components:
    - ONTAP version

◦ ESXi operating system version
◦ VMware vCenter Server version
◦ VMware Tools version
◦ Browser type and version

> The Interoperability Matrix lists the supported configurations for Unified Manager.

3. Click the configuration name for the selected configuration.

   Details for that configuration are displayed in the Configuration Details window.

4. Review the information in the following tabs:
   ◦ Notes

     Lists important alerts and information that are specific to your configuration.

   ◦ Policies and Guidelines

     Provides general guidelines for all configurations.

ONTAP Active IQ Unified Manager worksheet

Before you install, configure, and connect Active IQ Unified Manager, you should have specific information about your environment readily available. You can record the information in the worksheet.

Unified Manager installation information

Virtual machine on which software is deployed	Your value
ESXi server IP address	
Host fully qualified domain name	
Host IP address	
Network mask	
Gateway IP address	
Primary DNS address	
Secondary DNS address	
Search domains	
Maintenance user name	

Maintenance user password	

Unified Manager configuration information

Setting	Your value
Maintenance user email address	
NTP server	
SMTP server host name or IP address	
SMTP user name	
SMTP password	
SMTP default port	25 (Default value)
Email from which alert notifications are sent	
LDAP bind distinguished name	
LDAP bind password	
Active Directory administrator name	
Active Directory password	
Authentication server base distinguished name	
Authentication server host name or IP address	

Cluster information

Capture the following information for each cluster on Unified Manager.

Cluster 1 of N	Your value
Host name or cluster-management IP address	
ONTAP administrator user name ⓘ The administrator must have been assigned the "admin" role.	

ONTAP administrator password

Administrator authentication and RBAC

Install Active IQ Unified Manager

Download and deploy ONTAP Active IQ Unified Manager

To install the software, you must download the virtual appliance (VA) installation file and then use a VMware vSphere Client to deploy the file to a VMware ESXi server. The VA is available in an OVA file.

Steps

1. Go to the **NetApp Support Site Software Download** page and locate Active IQ Unified Manager.

   https://mysupport.netapp.com/products/index.html

2. Select **VMware vSphere** in the **Select Platform** drop-down menu and click **Go!**
3. Save the “OVA” file to a local or network location that is accessible to your VMware vSphere Client.
4. In VMware vSphere Client, click **File** > **Deploy OVF Template**.
5. Locate the “OVA” file and use the wizard to deploy the virtual appliance on the ESXi server.

   You can use the **Properties** tab in the wizard to enter your static configuration information.

6. Power on the VM.
7. Click the **Console** tab to view the initial boot process.
8. Follow the prompt to install VMware Tools on the VM.
9. Configure the time zone.
10. Enter a maintenance user name and password.
11. Go to the URL displayed by the VM console.

Configure initial ONTAP Active IQ Unified Manager settings

The Active IQ Unified Manager Initial Setup dialog box appears when you first access the web UI, which enables you to configure some initial settings and to add clusters.

Steps

1. Accept the default AutoSupport enabled setting.
2. Enter the NTP server details, the maintenance user email address, the SMTP server host name, and additional SMTP options, and then click **Save**.

After you finish

When the initial setup is complete, the Cluster Data Sources page is displayed where you can add the cluster details.

Specify the ONTAP clusters to be monitored in Active IQ Unified Manager

You must add a cluster to an Active IQ Unified Manager server to monitor the cluster, view the cluster discovery status, and monitor its performance.

Before you begin

- You must have the following information:
  - Host name or cluster-management IP address

    The host name is the fully qualified domain name (FQDN) or short name that Unified Manager uses to connect to the cluster. This host name must resolve to the cluster-management IP address.

    The cluster-management IP address must be the cluster-management LIF of the administrative storage virtual machine (SVM). If you use a node-management LIF, the operation fails.
  - ONTAP administrator user name and password
  - Type of protocol (HTTP or HTTPS) that can be configured on the cluster and the port number of the cluster
- You must have the Application Administrator or Storage Administrator role.
- The ONTAP administrator must have the ONTAPI and SSH administrator roles.
- The Unified Manager FQDN must be able to ping ONTAP.

  You can verify this by using the ONTAP command `ping -node` *`node_name`* `-destination` *`Unified_Manager_FQDN`*.

About this task

For a MetroCluster configuration, you must add both the local and remote clusters, and the clusters must be configured correctly.

Steps

1. Click **Configuration** > **Cluster Data Sources**.
2. From the Clusters page, click **Add**.
3. In the **Add Cluster** dialog box, specify the required values, such as the host name or IP address (IPv4 or IPv6) of the cluster, user name, password, protocol for communication, and port number.

   By default, the HTTPS protocol is selected.

   You can change the cluster-management IP address from IPv6 to IPv4 or from IPv4 to IPv6. The new IP address is reflected in the cluster grid and the cluster configuration page after the next monitoring cycle finishes.
4. Click **Add**.
5. If HTTPS is selected, perform the following steps:
   a. In the **Authorize Host** dialog box, click **View Certificate** to view the certificate information about the cluster.
   b. Click **Yes**.

      Unified Manager checks the certificate only when the cluster is initially added, but does not check it for each API call to ONTAP.

If the certificate has expired, you cannot add the cluster. You must renew the SSL certificate and then add the cluster.

6. **Optional**: View the cluster discovery status:

   a. Review the cluster discovery status from the **Cluster Setup** page.

   The cluster is added to the Unified Manager database after the default monitoring interval of approximately 15 minutes.

Set up basic monitoring tasks

Perform daily ONTAP Active IQ Unified Manager monitoring

You can perform daily monitoring to ensure that you do not have any immediate performance issues that require attention.

Steps

1. From the Active IQ Unified Manager UI, go to the **Event Inventory** page to view all current and obsolete events.
2. From the **View** option, select `Active Performance Events` and determine what action is required.

Use ONTAP Active IQ Unified Manager weekly and monthly performance trends to identify performance issues

Identifying performance trends can assist you in identifying whether the cluster is being overused or underused by analyzing volume latency. You can use similar steps to identify CPU, network, or other system bottlenecks.

Steps

1. Locate the volume that you suspect is being underused or overused.
2. On the **Volume Details** tab, click **30 d** to display the historical data.
3. In the "Break down data by" drop-down menu, select **Latency**, and then click **Submit**.
4. Deselect **Aggregate** in the cluster components comparison chart, and then compare the cluster latency with the volume latency chart.
5. Select **Aggregate** and deselect all other components in the cluster components comparison chart, and then compare the aggregate latency with the volume latency chart.
6. Compare the reads/writes latency chart to the volume latency chart.
7. Determine whether client application loads have caused a workload contention and rebalance workloads as needed.
8. Determine whether the aggregate is overused and causing contention and rebalance workloads as needed.

Use ONTAP Active IQ Unified Manager performance thresholds to generate event notifications

Events are notifications that the Active IQ Unified Manager generates automatically when a predefined condition occurs, or when a performance counter value crosses a threshold. Events help you identify performance issues in the clusters you are monitoring. You can configure alerts to send email notification automatically when events of certain severity types occur.

Set ONTAP performance thresholds

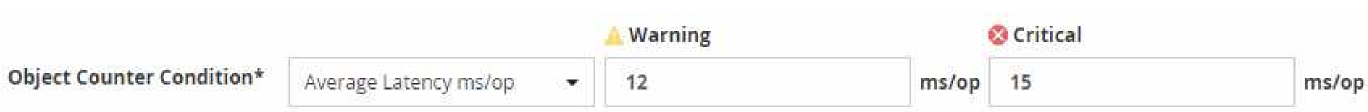
You can set performance thresholds to monitor critical performance issues. User-defined thresholds trigger a warning or a critical event notification when the system approaches or exceeds the defined threshold.

Steps

1. Create the Warning and Critical event thresholds:
   a. Select **Configuration** > **Performance Thresholds**.
   b. Click **Create**.
   c. Select the object type and specify a name and description of the policy.
   d. Select the object counter condition and specify the limit values that define Warning and Critical events.
   e. Select the duration of time that the limit values must be breached for an event to be sent, and then click **Save**.
2. Assign the threshold policy to the storage object.
   a. Go to the Inventory page for the same cluster object type that you previously selected and choose the **Performance** from the View option.
   b. Select the object to which you want to assign the threshold policy, and then click **Assign Threshold Policy**.
   c. Select the policy you previously created, and then click **Assign Policy**.

Example

You can set user-defined thresholds to learn about critical performance issues. For example, if you have a Microsoft Exchange Server and you know that it crashes if volume latency exceeds 20 milliseconds, you can set a warning threshold at 12 milliseconds and a critical threshold at 15 milliseconds. With this threshold setting, you can receive notifications when the volume latency exceeds the limit.



Add ONTAP Active IQ Unified Manager alerts

You can configure alerts to notify you when a particular event is generated. You can configure alerts for a single resource, for a group of resources, or for events of a particular severity type. You can specify the frequency with which you want to be notified and associate a script to the alert.

Before you begin

- You must have configured notification settings such as the user email address, SMTP server, and SNMP trap host to enable the Active IQ Unified Manager server to use these settings to send notifications to users when an event is generated.
- You must know the resources and events for which you want to trigger the alert, and the user names or email addresses of the users that you want to notify.
- If you want to have a script execute based on the event, you must have added the script to Unified

Manager by using the Scripts page.

- You must have the Application Administrator or Storage Administrator role.

About this task

You can create an alert directly from the Event details page after receiving an event in addition to creating an alert from the Alert Setup page, as described here.

Steps

1. In the left navigation pane, click **Storage Management** > **Alert Setup**.
2. In the **Alert Setup** page, click **Add**.
3. In the **Add Alert** dialog box, click **Name**, and enter a name and description for the alert.
4. Click **Resources**, and select the resources to be included in or excluded from the alert.

   You can set a filter by specifying a text string in the **Name contains** field to select a group of resources. Based on the text string that you specify, the list of available resources displays only those resources that match the filter rule. The text string that you specify is case-sensitive.

   If a resource conforms to both the include and exclude rules that you have specified, the exclude rule takes precedence over the include rule, and the alert is not generated for events related to the excluded resource.

5. Click **Events**, and select the events based on the event name or event severity type for which you want to trigger an alert.

   > To select more than one event, press the Ctrl key while you make your selections.

6. Click **Actions**, and select the users that you want to notify, choose the notification frequency, choose whether an SNMP trap will be sent to the trap receiver, and assign a script to be executed when an alert is generated.

   > If you modify the email address that is specified for the user and reopen the alert for editing, the Name field appears blank because the modified email address is no longer mapped to the user that was previously selected. Also, if you modified the email address of the selected user from the Users page, the modified email address is not updated for the selected user.

   You can also choose to notify users through SNMP traps.

7. Click **Save**.

Example of adding an alert

This example shows how to create an alert that meets the following requirements:

- Alert name: HealthTest
- Resources: includes all volumes whose name contains "abc" and excludes all volumes whose name contains "xyz"
- Events: includes all critical health events
- Actions: includes "sample@domain.com", a "Test" script, and the user has to be notified every 15 minutes

Perform the following steps in the Add Alert dialog box:

1. Click **Name**, and enter `HealthTest` in the **Alert Name** field.
2. Click **Resources**, and in the Include tab, select **Volumes** from the drop-down list.
   a. Enter `abc` in the **Name contains** field to display the volumes whose name contains "abc".
   b. Select **<<All Volumes whose name contains 'abc'>>** from the Available Resources area, and move it to the Selected Resources area.
   c. Click **Exclude**, and enter `xyz` in the **Name contains** field, and then click **Add**.
3. Click **Events**, and select **Critical** from the Event Severity field.
4. Select **All Critical Events** from the Matching Events area, and move it to the Selected Events area.
5. Click **Actions**, and enter `sample@domain.com` in the Alert these users field.
6. Select **Remind every 15 minutes** to notify the user every 15 minutes.

   You can configure an alert to repeatedly send notifications to the recipients for a specified time. You should determine the time from which the event notification is active for the alert.

7. In the Select Script to Execute menu, select **Test** script.
8. Click **Save**.

Configure ONTAP Active IQ Unified Manager alert settings

You can specify which events from Active IQ Unified Manager trigger alerts, the email recipients for those alerts, and the frequency for the alerts.

Before you begin

You must have the Application Administrator role.

About this task

You can configure unique alert settings for the following types of performance events:

- Critical events triggered by breaches of user-defined thresholds
- Warning events triggered by breaches of user-defined thresholds, system-defined thresholds, or dynamic thresholds

By default, email alerts are sent to Unified Manager admin users for all new events. You can have email alerts sent to other users by adding those users' email addresses.

> ⓘ To disable alerts from being sent for certain types of events, you must clear all of the check boxes in an event category. This action does not stop events from appearing in the user interface.

Steps

1. In the left navigation pane, select **Storage Management** > **Alert Setup**.

   The Alert Setup page is displayed.

2. Click **Add** and configure the appropriate settings for each of the event types.

   To have email alerts sent to multiple users, enter a comma between each email address.

3. Click **Save**.

Identify performance issues in ONTAP Active IQ Unified Manager

If a performance event occurs, you can locate the source of the issue within Active IQ Unified Manager and use other tools to fix it. You might receive an email notification of an event or notice the event during daily monitoring.

Steps

1. Click the link in the email notification, which takes you directly to the storage object having a performance event.

If you…	Then…
Receive an email notification of an event	Click the link to go directly to the event details page.
Notice the event while analyzing the Event Inventory page	Select the event to go directly to the event details page.

2. If the event has crossed a system-defined threshold, follow the suggested actions in the UI to troubleshoot the issue.
3. If the event has crossed a user-defined threshold, analyze the event to determine if you need to take action.
4. If the issue persists, check the following settings:
   - Protocol settings on the storage system
   - Network settings on any Ethernet or fabric switches
   - Network settings on the storage system
   - Disk layout and aggregate metrics on the storage system
5. If the issue persists, contact technical support for assistance.

Use ONTAP Active IQ Digital Advisor to view system performance

For any ONTAP system that sends AutoSupport telemetry to NetApp, you can view extensive performance and capacity data. Digital Advisor shows system performance over a longer period than you can see in System Manager.

You can view graphs of CPU utilization, latency, IOPS, IOPS by protocol, and network throughput. You can also download this data in .csv format for analysis in other tools.

In addition to this performance data, Digital Advisor can show you storage efficiency by workload and compare that efficiency to the expected efficiency for that type of workload. You can view capacity trends and see an estimate of how much additional storage you might need to add in a given time frame.

- Storage Efficiency is available at the customer, cluster, and node level on the left-hand-side of the main dashboard.
- Performance is available at the cluster and node level on the left-hand-side of the main dashboard.

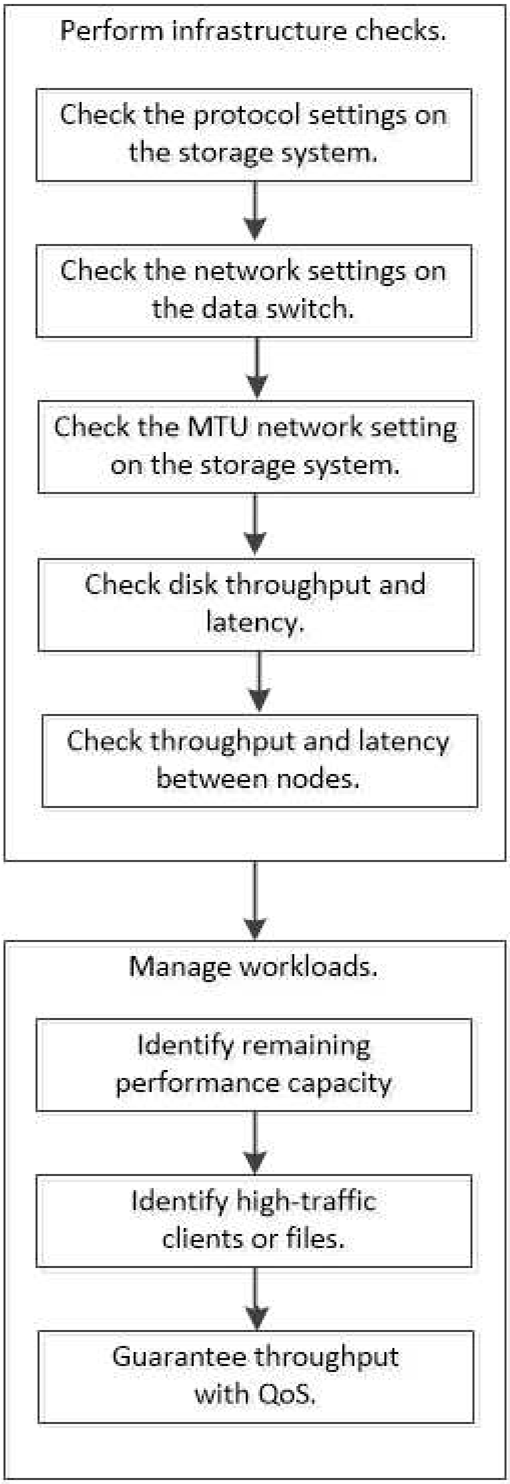
Manage performance issues

ONTAP performance management workflow

Once you have identified a performance issue, you can conduct some basic diagnostic checks of your infrastructure to rule out obvious configuration errors. If those don’t pinpoint the problem, you can start looking at workload management issues.



Perform basic infrastructure checks

Check protocol settings on the storage system

Check the ONTAP NFS TCP maximum transfer size

For NFS, you can check whether the TCP maximum transfer size for reads and writes might be causing a performance issue. If you think the size is slowing performance, you can increase it.

Before you begin

- You must have cluster administrator privileges to perform this task.
- You must use advanced privilege level commands for this task.

Steps

1. Change to the advanced privilege level:

   `set -privilege advanced`

2. Check the TCP maximum transfer size:

   `vserver nfs show -vserver *vserver_name* -instance`

3. If the TCP maximum transfer size is too small, increase the size:

   `vserver nfs modify -vserver *vserver_name* -tcp-max-xfer-size *integer*`

4. Return to the administrative privilege level:

   `set -privilege admin`

Example

The following example changes the TCP maximum transfer size of `SVM1` to 1048576:

```
cluster1::*> vserver nfs modify -vserver SVM1 -tcp-max-xfer-size 1048576
```

Check the ONTAP iSCSI TCP read/write size

For iSCSI, you can check the TCP read/write size to determine if the size setting is creating a performance issue. If the size is the source of an issue, you can correct it.

Before you begin

Advanced privilege level commands are required for this task.

Steps

1. Change to advanced privilege level:

   `set -privilege advanced`

2. Check the TCP window size setting:

   `vserver iscsi show -vserv,er *vserver_name* -instance`

3. Modify the TCP window size setting:

   `vserver iscsi modify -vserver *vserver_name* -tcp-window-size *integer*`

4. Return to administrative privilege:

   `set -privilege admin`

Example

The following example changes the TCP window size of `SVM1` to 131,400 bytes:

```
cluster1::*> vserver iscsi modify -vserver vs1 -tcp-window-size 131400
```

Check the ONTAP CIFS/SMB multiplex settings

If slow CIFS network performance causes a performance issue, you can modify the multiplex settings to improve and correct it.

Steps

1. Check the CIFS multiplex setting:

   `vserver cifs options show -vserver -vserver_name -instance`

2. Modify the CIFS multiplex setting:

   `vserver cifs options modify –vserver -vserver_name –max-mpx integer`

Example

The following example changes the maximum multiplex count on `SVM1` to 255:

```
cluster1::> vserver cifs options modify -vserver SVM1 -max-mpx 255
```

Check the ONTAP FC adapter port speed

The adapter target port speed should match the speed of the device to which it connects, to optimize performance. If the port is set to autonegotiation, it can take longer to reconnect after a takeover and giveback or other interruption.

Before you begin

All LIFs that use this adapter as their home port must be offline.

Steps

1. Take the adapter offline:

   `network fcp adapter modify -node nodename -adapter adapter -state down`

   Learn more about `network fcp adapter modify` in the ONTAP command reference.

2. Check the maximum speed of the port adapter:

   `fcp adapter show -instance`

   Learn more about `fcp adapter show` in the ONTAP command reference.

3. Change the port speed, if necessary:

```
network fcp adapter modify -node nodename -adapter adapter -speed
{1|2|4|8|10|16|auto}
```

4. Bring the adapter online:

```
network fcp adapter modify -node nodename -adapter adapter -state up
```

5. Bring all the LIFs on the adapter online:

```
network interface modify -vserver * -lif * { -home-node node1 -home-port e0c }
-status-admin up
```

Learn more about `network interface modify` in the ONTAP command reference.

Example

The following example changes the port speed of adapter `0d` on `node1` to 2 Gbps:

```
cluster1::> network fcp adapter modify -node node1 -adapter 0d -speed 2
```

Check the ONTAP network settings on the data switches

Although you must maintain the same MTU settings on your clients, servers and storage systems (that is, network endpoints), intermediate network devices such as NICs and switches should be set to their maximum MTU values to ensure that performance is not impacted.

For best performance, all components in the network must be able to forward jumbo frames (9000 bytes IP, 9022 bytes including Ethernet). Data switches should be set to at least 9022 bytes, but a typical value of 9216 is possible with most switches.

Steps

1. For data switches, check that the MTU size is set to 9022 or higher.

For more information, see the switch vendor documentation.

Check the ONTAP MTU network setting on the storage system

You can change the network settings on the storage system if they are not the same as on the client or other network endpoints. Whereas the management network MTU setting is set to 1500, the data network MTU size should be 9000.

About this task

All ports within a broadcast-domain have the same MTU size, with the exception of the e0M port handling management traffic. If the port is part of a broadcast-domain, use the `broadcast-domain modify` command to change the MTU for all ports within the modified broadcast-domain.

Note that intermediate network devices such as NICs and data switches can be set to higher MTU sizes than network endpoints. For more information, see Check the network settings on the data switches.

Steps

1. Check the MTU port setting on the storage system:

   `network port show -instance`

   Learn more about `network port show` in the ONTAP command reference.

2. Change the MTU on the broadcast domain used by the ports:

   `network port broadcast-domain modify -ipspace` *`ipspace`* `-broadcast-domain` *`broadcast_domain`* `-mtu` *`new _mtu`*

Example

The following example changes the MTU port setting to 9000:

```
network port broadcast-domain modify -ipspace Cluster -broadcast-domain
Cluster -mtu 9000
```

Check ONTAP disk throughput and latency

You can check the disk throughput and latency metrics for cluster nodes to assist you in troubleshooting.

About this task

Advanced privilege level commands are required for this task.

Steps

1. Change to advanced privilege level:

   ```
   set -privilege advanced
   ```

2. Check the disk throughput and latency metrics:

   ```
   statistics disk show -sort-key latency
   ```

Example

The following example displays the totals in each user read or write operation for `node2` on `cluster1`:

```
::*> statistics disk show -sort-key latency
cluster1 : 8/24/2015 12:44:15
                    Busy Total Read  Write  Read    Write   *Latency
  Disk         Node  (%)   Ops   Ops   Ops   (Bps)   (Bps)      (us)
------------ ----   ---- ----   ----- ----- ------   -----    -----

1.10.20      node2     4    5       3     2  95232  367616    23806
1.10.8       node2     4    5       3     2 138240  386048    22113

1.10.6       node2     3    4       2     2  48128  371712    19113
1.10.19      node2     4    6       3     2 102400  443392    19106

1.10.11      node2     4    4       2     2 122880  408576    17713
```

Check ONTAP throughput and latency between nodes

You can use the `network test-path` command to identify network bottlenecks, or to prequalify network paths between nodes. You can run the command between intercluster nodes or intracluster nodes.

Before you begin

- You must be a cluster administrator to perform this task.
- Advanced privilege level commands are required for this task.
- For an intercluster path, the source and destination clusters must be peered.

About this task

Occasionally, network performance between nodes may not meet expectations for your path configuration. A 1 Gbps transmission rate for the kind of large data transfers seen in SnapMirror replication operations, for example, would not be consistent with a 10 GbE link between the source and destination clusters.

You can use the `network test-path` command to measure throughput and latency between nodes. You can run the command between intercluster nodes or intracluster nodes.

> The test saturates the network path with data, so you should run the command when the system is not busy and when network traffic between nodes is not excessive. The test times out after ten seconds. The command can be run only between ONTAP 9 nodes.

The `session-type` option identifies the type of operation you are running over the network path—for example, "AsyncMirrorRemote" for SnapMirror replication to a remote destination. The type dictates the amount of data used in the test. The following table defines the session types:

Session Type	Description

AsyncMirrorLocal	Settings used by SnapMirror between nodes in the same cluster
AsyncMirrorRemote	Settings used by SnapMirror between nodes in different clusters (default type)
RemoteDataTransfer	Settings used by ONTAP for remote data access between nodes in the same cluster (for example, an NFS request to a node for a file stored in a volume on a different node)

Steps

1. Change to advanced privilege level:

   `set -privilege advanced`

2. Measure throughput and latency between nodes:

   `network test-path -source-node` *`source_nodename`* `|local -destination-cluster` *`destination_clustername`* `-destination-node` *`destination_nodename`* `-session-type Default|AsyncMirrorLocal|AsyncMirrorRemote|SyncMirrorRemote|RemoteDataTransfer`

   The source node must be in the local cluster. The destination node can be in the local cluster or in a peered cluster. A value of "local" for `-source-node` specifies the node on which you are running the command.

   The following command measures throughput and latency for SnapMirror-type replication operations between `node1` on the local cluster and `node3` on `cluster2`:

   ```
   cluster1::> network test-path -source-node node1 -destination-cluster
   cluster2 -destination-node node3 -session-type AsyncMirrorRemote
   ```

   Sample output (output details might vary depending on your version of ONTAP):

   ```
   Test Duration:      10.88 secs
   Send Throughput:    18.23 MB/sec
   Receive Throughput: 18.23 MB/sec
   MB sent:            198.31
   MB received:        198.31
   Avg latency in ms:  2301.47
   ```

   Learn more about `network test-path` in the ONTAP command reference.

3. Return to administrative privilege:

   `set -privilege admin`

After you finish

If performance does not meet expectations for the path configuration, you should check node performance statistics, use available tools to isolate the problem in the network, check switch settings, and so forth.

Manage workloads

Identify remaining performance capacity in ONTAP

Performance capacity, or *headroom*, measures how much work you can place on a node or an aggregate before performance of workloads on the resource begins to be affected by latency. Knowing the available performance capacity on the cluster helps you provision and balance workloads.

Before you begin

Advanced privilege level commands are required for this task.

About this task

You can use the following values for the `-object` option to collect and display headroom statistics:

- For CPUs, `resource_headroom_cpu`.
- For aggregates, `resource_headroom_aggr`.

You can also complete this task using System Manager and Active IQ Unified Manager.

Steps

1. Change to advanced privilege level:

   ```
   set -privilege advanced
   ```

2. Start real-time headroom statistics collection:

   ```
   statistics start –object resource_headroom_cpu|aggr
   ```

   Learn more about `statistics start` in the ONTAP command reference.

3. Display real-time headroom statistics information:

   ```
   statistics show -object resource_headroom_cpu|aggr
   ```

4. Return to administrative privilege:

   ```
   set -privilege admin
   ```

Example

The following example displays the average hourly headroom statistics for cluster nodes.

You can compute the available performance capacity for a node by subtracting the `current_utilization` counter from the `optimal_point_utilization` counter. In this example, the utilization capacity for `CPU_sti2520-213` is -14% (72%-86%), which suggests that the CPU has been overutilized on average for the past hour.

You could have specified `ewma_daily`, `ewma_weekly`, or `ewma_monthly` to get the same information averaged over longer periods of time.

```
sti2520-2131454963690::*> statistics show -object resource_headroom_cpu
-raw -counter ewma_hourly
  (statistics show)

Object: resource_headroom_cpu
Instance: CPU_sti2520-213
Start-time: 2/9/2016 16:06:27
End-time: 2/9/2016 16:06:27
Scope: sti2520-213

    Counter                                                     Value
    -------------------------------- --------------------------------
    ewma_hourly                                                     -
                         current_ops                             4376
                     current_latency                            37719
                 current_utilization                               86
                   optimal_point_ops                             2573
               optimal_point_latency                             3589
           optimal_point_utilization                               72
     optimal_point_confidence_factor                                1

Object: resource_headroom_cpu
Instance: CPU_sti2520-214

2 entries were displayed.
```

Learn more about `statistics show` in the ONTAP command reference.

You can use ONTAP Active Objects technology to identify clients or files that are responsible for a disproportionately large amount of cluster traffic. Once you have identified these "top" clients or files, you can rebalance cluster workloads or take other steps to resolve the issue.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. View the top clients accessing the cluster:

   `statistics top client show -node` *`node_name`* `-sort-key` *`sort_column`* `-interval` *`seconds_between_updates`* `-iterations` *`iterations`* `-max` *`number_of_instances`*

   The following command displays the top clients accessing `cluster1`:

   ```
   cluster1::> statistics top client show

   cluster1 : 3/23/2016 17:59:10

                                                          *Total
           Client Vserver           Node Protocol    Ops
   -------------- ------- -------------- -------- ------
   172.17.180.170     vs4 siderop1-vsim4      nfs    668
   172.17.180.169     vs3 siderop1-vsim3      nfs    337
   172.17.180.171     vs3 siderop1-vsim3      nfs    142
   172.17.180.170     vs3 siderop1-vsim3      nfs    137
   172.17.180.123     vs3 siderop1-vsim3      nfs    137
   172.17.180.171     vs4 siderop1-vsim4      nfs     95
   172.17.180.169     vs4 siderop1-vsim4      nfs     92
   172.17.180.123     vs4 siderop1-vsim4      nfs     92
   172.17.180.153     vs3 siderop1-vsim3      nfs      0
   ```

   Learn more about `statistics top client show` in the ONTAP command reference.

2. View the top files accessed on the cluster:

   `statistics top file show -node` *`node_name`* `-sort-key` *`sort_column`* `-interval` *`seconds_between_updates`* `-iterations` *`iterations`* `-max` *`number_of_instances`*

   The following command displays the top files accessed on `cluster1`:

```
cluster1::> statistics top file show

cluster1 : 3/23/2016 17:59:10

                                        *Total
                        File Volume Vserver          Node    Ops
------------------------- ------ ------- -------------- ------
/vol/vol1/vm170-read.dat   vol1     vs4 siderop1-vsim4     22
/vol/vol1/vm69-write.dat   vol1     vs3 siderop1-vsim3      6
     /vol/vol2/vm171.dat   vol2     vs3 siderop1-vsim3      2
     /vol/vol2/vm169.dat   vol2     vs3 siderop1-vsim3      2
      /vol/vol2/p123.dat   vol2     vs4 siderop1-vsim4      2
      /vol/vol2/p123.dat   vol2     vs3 siderop1-vsim3      2
     /vol/vol1/vm171.dat   vol1     vs4 siderop1-vsim4      2
     /vol/vol1/vm169.dat   vol1     vs4 siderop1-vsim4      2
     /vol/vol1/vm169.dat   vol1     vs4 siderop1-vsim3      2
      /vol/vol1/p123.dat   vol1     vs4 siderop1-vsim4      2
```

Learn more about `statistics top file show` in the ONTAP command reference.

Guarantee throughput with QoS

Guarantee throughput with QoS overview in ONTAP

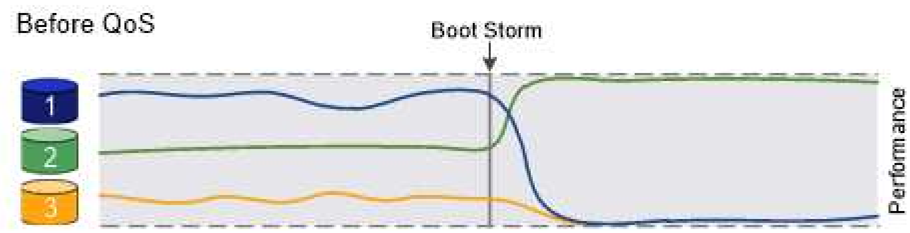
You can use storage quality of service (QoS) to guarantee that performance of critical workloads is not degraded by competing workloads. You can set a throughput *ceiling* on a competing workload to limit its impact on system resources, or set a throughput *floor* for a critical workload, ensuring that it meets minimum throughput targets, regardless of demand by competing workloads. You can even set a ceiling and floor for the same workload.

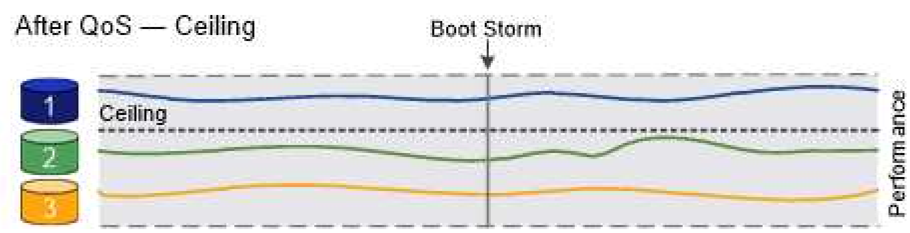
Throughput ceilings (QoS Max)

A throughput ceiling limits throughput for a workload to a maximum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput ceiling for workload 2 ensures that it does not "bully" workloads 1 and 3.

A *policy group* defines the throughput ceiling for one or more workloads. A workload represents the I/O operations for a *storage object:* a volume, file, qtree or LUN, or all the volumes, files, qtrees, or LUNs in an SVM. You can specify the ceiling when you create the policy group, or you can wait until after you monitor workloads to specify it.

> Throughput to workloads might exceed the specified ceiling by up to 10%, especially if a workload experiences rapid changes in throughput. The ceiling might be exceeded by up to 50% to handle bursts. Bursts occur on single nodes when tokens accumulate up to 150%





Throughput floors (QoS Min)

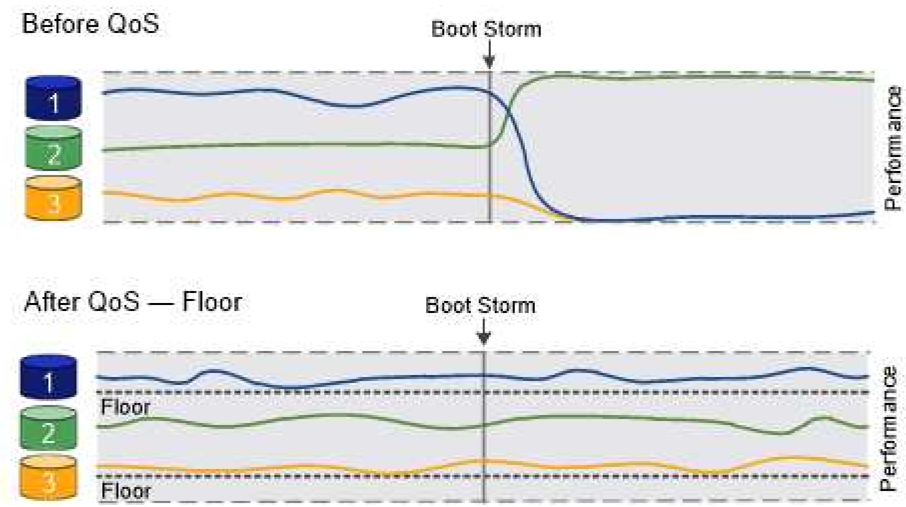
A throughput floor guarantees that throughput for a workload does not fall below a minimum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput floors for workload 1 and workload 3 ensure that they meet minimum throughput targets, regardless of demand by workload 2.

> As the examples suggest, a throughput ceiling throttles throughput directly. A throughput floor throttles throughput indirectly, by giving priority to the workloads for which the floor has been set.

You can specify the floor when you create the policy group, or you can wait until after you monitor workloads to specify it.

Beginning with ONTAP 9.13.1, you can set throughput floors at the SVM scope with Adaptive policy group templates. In releases of ONTAP before 9.13.1, a policy group that defines a throughput floor cannot be applied to an SVM.

> In releases before ONTAP 9.7, throughput floors are guaranteed when there is sufficient performance capacity available.
>
> In ONTAP 9.7 and later, throughput floors can be guaranteed even when there is insufficient performance capacity available. This new floor behavior is called floors v2. To meet the guarantees, floors v2 can result in higher latency on workloads without a throughput floor or on work that exceeds the floor settings. Floors v2 applies to both QoS and adaptive QoS.
>
> The option of enabling/disabling the new behavior of floors v2 is available in ONTAP 9.7P6 and later. A workload might fall below the specified floor during critical operations like `volume move trigger-cutover`. Even when sufficient capacity is available and critical operations are not taking place, throughput to a workload might fall below the specified floor by up to 5%. If floors are overprovisioned and there is no performance capacity, some workloads might fall below the specified floor.



Shared and non-shared QoS policy groups

Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput ceiling or floor applies to each member workload individually. Behavior of *shared* policy groups depends on the policy type:

- For throughput ceilings, the total throughput for the workloads assigned to the shared policy group cannot exceed the specified ceiling.
- For throughput floors, the shared policy group can be applied to a single workload only.

Adaptive QoS

Ordinarily, the value of the policy group you assign to a storage object is fixed. You need to change the value manually when the size of the storage object changes. An increase in the amount of space used on a volume, for example, usually requires a corresponding increase in the throughput ceiling specified for the volume.

Adaptive QoS automatically scales the policy group value to workload size, maintaining the ratio of IOPS to TBs|GBs as the size of the workload changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

You typically use adaptive QoS to adjust throughput ceilings, but you can also use it to manage throughput floors (when workload size increases). Workload size is expressed as either the allocated space for the storage object or the space used by the storage object.

> Used space is available for throughput floors in ONTAP 9.5 and later. It is not supported for throughput floors in ONTAP 9.4 and earlier.

- An *allocated space* policy maintains the IOPS/TB|GB ratio according to the nominal size of the storage object. If the ratio is 100 IOPS/GB, a 150 GB volume will have a throughput ceiling of 15,000 IOPS for as long as the volume remains that size. If the volume is resized to 300 GB, adaptive QoS adjusts the throughput ceiling to 30,000 IOPS.
- A *used space* policy (the default) maintains the IOPS/TB|GB ratio according to the amount of actual data stored before storage efficiencies. If the ratio is 100 IOPS/GB, a 150 GB volume that has 100 GB of data stored would have a throughput ceiling of 10,000 IOPS. As the amount of used space changes, adaptive QoS adjusts the throughput ceiling according to the ratio.

Beginning with ONTAP 9.5, you can specify an I/O block size for your application that enables a throughput limit to be expressed in both IOPS and MBps. The MBps limit is calculated from the block size multiplied by the

IOPS limit. For example, an I/O block size of 32K for an IOPS limit of 6144IOPS/TB yields an MBps limit of 192MBps.

You can expect the following behavior for both throughput ceilings and floors:

- When a workload is assigned to an adaptive QoS policy group, the ceiling or floor is updated immediately.
- When a workload in an adaptive QoS policy group is resized, the ceiling or floor is updated in approximately five minutes.

Throughput must increase by at least 10 IOPS before updates take place.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

Beginning with ONTAP 9.6, throughput floors are supported on ONTAP Select premium with SSD.

Adaptive policy group template

Beginning with ONTAP 9.13.1, you can set an adaptive QoS template on an SVM. Adaptive policy group templates enable you to set throughput floors and ceilings for all volumes in an SVM.

Adaptive policy group templates can only be set after the SVM has been created. Use the `vserver modify` command with the `-qos-adaptive-policy-group-template` parameter to set the policy.

When you set an an adaptive policy group template, volumes created or migrated after setting the policy automatically inherit the policy. Any volumes existing on the SVM are not impacted when you assign the policy template. If you disable the policy on the SVM, any volume subsequently migrated to or created on the SVM will not receive the policy. Disabling the adaptive policy group template does not impact volumes that inherited the policy template as they retain the policy template.

For more information, see Set an adaptive policy group template.

General support

The following table shows the differences in support for throughput ceilings, throughput floors, and adaptive QoS.

Resource or feature	Throughput ceiling	Throughput floor	Throughput floor v2	Adaptive QoS
ONTAP 9 version	All	9.2 and later	9.7 and later	9.3 and later
Platforms	All	• AFF • C190 [1] • ONTAP Select premium with SSD [1]	• AFF • C190 • ONTAP Select premium with SSD	All
Protocols	All	All	All	All

Resource or feature	Throughput ceiling	Throughput floor	Throughput floor v2	Adaptive QoS
FabricPool	Yes	Yes, if the tiering policy is set to "none" and no blocks are in the cloud.	Yes, if the tiering policy is set to "none" and no blocks are in the cloud.	No
SnapMirror Synchronous	Yes	No	No	Yes

[1] C190 and ONTAP Select support started with the ONTAP 9.6 release.

Supported workloads for throughput ceilings

The following table shows workload support for throughput ceilings by ONTAP 9 version. Root volumes, load-sharing mirrors, and data protection mirrors are not supported.

Workload support	ONTAP 9.3 and earlier	ONTAP 9.4 to 9.7	ONTAP 9.8 and later
Volume	yes	yes	yes
File	yes	yes	yes
LUN	yes	yes	yes
SVM	yes	yes	yes
FlexGroup volume	yes (ONTAP 9.3 only)	yes	yes
qtrees [1]	no	no	yes
Multiple workloads per policy group	yes	yes	yes
Non-shared policy groups	no	yes	yes

[1] Beginning with ONTAP 9.8, NFS access is supported in qtrees in FlexVol and FlexGroup volumes with NFS enabled. Beginning with ONTAP 9.9.1, SMB access is also supported in qtrees in FlexVol and FlexGroup volumes with SMB enabled.

Supported workloads for throughput floors

The following table shows workload support for throughput floors by ONTAP 9 version. Root volumes, load-sharing mirrors, and data protection mirrors are not supported.

Workload support	ONTAP 9.3	ONTAP 9.4 to 9.7	ONTAP 9.8 to 9.13.0	ONTAP 9.13.1 and later
Volume	yes	yes	yes	yes
File	yes	yes	yes	yes
LUN	yes	yes	yes	yes
SVM	no	no	no	yes
FlexGroup volume	no	yes	yes	yes
qtrees [1]	no	no	yes	yes
Multiple workloads per policy group	no	yes	yes	yes
Non-shared policy groups	no	yes	yes	yes

[1] Beginning with ONTAP 9.8, NFS access is supported in qtrees in FlexVol and FlexGroup volumes with NFS enabled. Beginning with ONTAP 9.9.1, SMB access is also supported in qtrees in FlexVol and FlexGroup volumes with SMB enabled.

Supported workloads for adaptive QoS

The following table shows workload support for adaptive QoS by ONTAP 9 version. Root volumes, load-sharing mirrors, and data protection mirrors are not supported.

Workload support	ONTAP 9.3	ONTAP 9.4 to 9.13.0	ONTAP 9.13.1 and later
Volume	yes	yes	yes
File	no	yes	yes
LUN	no	yes	yes
SVM	no	no	yes
FlexGroup volume	no	yes	yes
Multiple workloads per policy group	yes	yes	yes
Non-shared policy groups	yes	yes	yes

Maximum number of workloads and policy groups

The following table shows the maximum number of workloads and policy groups by ONTAP 9 version.

Workload support	ONTAP 9.3 and earlier	ONTAP 9.4 and later
Maximum workloads per cluster	12,000	40,000
Maximum workloads per node	12,000	40,000
Maximum policy groups	12,000	12,000

Enable or disable ONTAP throughput floors v2

You can enable or disable throughput floors v2 on AFF. The default is enabled. With floors v2 enabled, throughput floors can be met when controllers are heavily used at the expense of higher latency on other workloads. Floors v2 applies to both QoS and Adaptive QoS.

Steps

1. Change to advanced privilege level:

   `set -privilege advanced`

2. Enter one of the following commands:

If you want to…	Use this command:
Disable floors v2	`qos settings throughput-floors-v2 -enable false`
Enable floors v2	`qos settings throughput-floors-v2 -enable true`

> ⓘ To disable throughput floors v2 in an MetroCluster cluster, you must run the
>
> `qos settings throughput-floors-v2 -enable false`
>
> command on both the source and destination clusters.

```
cluster1::*> qos settings throughput-floors-v2 -enable false
```

Learn more about `qos settings throughput-floors-v2` in the ONTAP command reference.

ONTAP storage QoS workflow

If you already know the performance requirements for the workloads you want to manage with QoS, you can specify the throughput limit when you create the policy group. Otherwise, you can wait until after you monitor the workloads to specify the limit.

Set a throughput ceiling with QoS in ONTAP

You can use the `max-throughput` field for a policy group to define a throughput ceiling for storage object workloads (QoS Max). You can apply the policy group when you create or modify the storage object.

Before you begin

- You must be a cluster administrator to create a policy group.
- You must be a cluster administrator to apply a policy group to an SVM.

About this task

- Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput ceiling applies to each member workload individually. Otherwise, the policy group is *shared:* the total throughput for the workloads assigned to the policy group cannot exceed the specified ceiling.

  Set `-is-shared=false` for the `qos policy-group create` command to specify a non-shared policy group.

- You can specify the throughput limit for the ceiling in IOPS, MB/s, or IOPS, MB/s. If you specify both IOPS and MB/s, whichever limit is reached first is enforced.

  > If you set a ceiling and a floor for the same workload, you can specify the throughput limit for the ceiling in IOPS only.

- A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
- You cannot assign a storage object to a policy group if its containing object or its child objects belong to the policy group.
- It is a QoS best practice to apply a policy group to the same type of storage objects.

Steps

1. Create a policy group:

   `qos policy-group create -policy-group` *`policy_group`* `-vserver` *`SVM`* `-max -throughput` *`number_of_iops`*`|Mb/S|iops,Mb/S -is-shared true|false`

   Learn more about `qos policy-group create` in the ONTAP command reference.

   You can use the `qos policy-group modify` command to adjust throughput ceilings.

   The following command creates the shared policy group `pg-vs1` with a maximum throughput of 5,000 IOPS:

   ```
   cluster1::> qos policy-group create -policy-group pg-vs1 -vserver vs1
   -max-throughput 5000iops -is-shared true
   ```

   The following command creates the non-shared policy group `pg-vs3` with a maximum throughput of 100 IOPS and 400 Kb/S:

   ```
   cluster1::> qos policy-group create -policy-group pg-vs3 -vserver vs3
   -max-throughput 100iops,400KB/s -is-shared false
   ```

   The following command creates the non-shared policy group `pg-vs4` without a throughput limit:

```
cluster1::> qos policy-group create -policy-group pg-vs4 -vserver vs4
-is-shared false
```

Learn more about `qos policy-group modify` in the ONTAP command reference.

2. Apply a policy group to an SVM, file, volume, or LUN:

   storage_object `create -vserver` *SVM* `-qos-policy-group` *policy_group*

   Learn more about the commands described in this procedure in the ONTAP command reference.
   You can use the *storage_object* `modify` command to apply a different policy group to the storage object.

   The following command applies policy group `pg-vs1` to SVM `vs1`:

```
cluster1::> vserver create -vserver vs1 -qos-policy-group pg-vs1
```

   The following commands apply policy group `pg-app` to the volumes `app1` and `app2`:

```
cluster1::> volume create -vserver vs2 -volume app1 -aggregate aggr1
-qos-policy-group pg-app
```

```
cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1
-qos-policy-group pg-app
```

3. Monitor policy group performance:

   `qos statistics performance show`

   Learn more about `qos statistics performance show` in the ONTAP command reference.

   Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

   The following command shows policy group performance:

```
cluster1::> qos statistics performance show
Policy Group           IOPS      Throughput   Latency
-------------------- -------- --------------- ----------
-total-                 12316       47.76MB/s  1264.00us
pg_vs1                   5008       19.56MB/s     2.45ms
_System-Best-Effort        62       13.36KB/s     4.13ms
_System-Background         30           0KB/s        0ms
```

4. Monitor workload performance:

   `qos statistics workload performance show`

   > Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

   The following command shows workload performance:

```
cluster1::> qos statistics workload performance show
Workload            ID      IOPS       Throughput     Latency
--------------- ------ --------- ---------------- ----------
-total-              -     12320        47.84MB/s  1215.00us
app1-wid7967      7967      7219        28.20MB/s   319.00us
vs1-wid12279     12279      5026        19.63MB/s     2.52ms
_USERSPACE_APPS     14        55        10.92KB/s   236.00us
_Scan_Backgro..   5688        20            0KB/s        0ms
```

   Learn more about `qos statistics workload performance show` in the ONTAP command reference.

   > You can use the `qos statistics workload latency show` command to view detailed latency statistics for QoS workloads.
   > Learn more about `qos statistics workload latency show` in the ONTAP command reference.

Set a throughput floor with QoS in ONTAP

You can use the `min-throughput` field for a policy group to define a throughput floor for storage object workloads (QoS Min). You can apply the policy group when you create or modify the storage object. Beginning with ONTAP 9.8, you can specify the throughput floor in IOPS or MBps, or IOPS and MBps.

Before you begin

- You must be a cluster administrator to create a policy group.
- Beginning with ONTAP 9.13.1, you can enforce throughput floors at the SVM level using an adaptive policy group template. You cannot set an adaptive policy group template on an SVM with a QoS policy group.

About this task

- Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput floor be applied to each member workload individually. This is the only condition in which a policy group for a throughput floor can be applied to multiple workloads.

  Set `-is-shared=false` for the `qos policy-group create` command to specify a non-shared policy group.

- Throughput to a workload might fall below the specified floor if there is insufficient performance capacity (headroom) on the node or aggregate.

- A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
- It is a QoS best practice to apply a policy group to the same type of storage objects.
- A policy group that defines a throughput floor cannot be applied to an SVM.

Steps

1. Check for adequate performance capacity on the node or aggregate, as described in Identifying remaining performance capacity.
2. Create a policy group:

   `qos policy-group create -policy group` *`policy_group`* `-vserver` *`SVM`* `-min -throughput` *`qos_target`* `-is-shared true|false`

   Learn more about `qos policy-group create` in the ONTAP command reference.

3. You can use the `qos policy-group modify` command to adjust throughput floors.

   The following command creates the shared policy group `pg-vs2` with a minimum throughput of 1,000 IOPS:

   ```
   cluster1::> qos policy-group create -policy group pg-vs2 -vserver vs2
   -min-throughput 1000iops -is-shared true
   ```

   The following command creates the non-shared policy group `pg-vs4` without a throughput limit:

   ```
   cluster1::> qos policy-group create -policy group pg-vs4 -vserver vs4
   -is-shared false
   ```

   Learn more about `qos policy-group modify` in the ONTAP command reference.

4. Apply a policy group to a volume or LUN:

   `storage_object` `create -vserver` *`SVM`* `-qos-policy-group` *`policy_group`*
   You can use the `_storage_object_modify` command to apply a different policy group to the storage object.

   The following command applies policy group `pg-app2` to the volume `app2`:

   ```
   cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1
   -qos-policy-group pg-app2
   ```

   Learn more about the commands described in this procedure in the ONTAP command reference.

5. Monitor policy group performance:

   `qos statistics performance show`

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows policy group performance:

```
cluster1::> qos statistics performance show
Policy Group           IOPS      Throughput   Latency
-------------------- -------- --------------- ----------
-total-                 12316       47.76MB/s  1264.00us
pg_app2                  7216       28.19MB/s   420.00us
_System-Best-Effort        62       13.36KB/s     4.13ms
_System-Background         30           0KB/s        0ms
```

Learn more about `qos statistics performance show` in the ONTAP command reference.

6. Monitor workload performance:

`qos statistics workload performance show`

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows workload performance:

```
cluster1::> qos statistics workload performance show
Workload           ID      IOPS       Throughput     Latency
--------------- ------ -------- ---------------- ----------
-total-              -    12320        47.84MB/s  1215.00us
app2-wid7967      7967     7219        28.20MB/s   319.00us
vs1-wid12279     12279     5026        19.63MB/s     2.52ms
_USERSPACE_APPS     14       55        10.92KB/s   236.00us
_Scan_Backgro..   5688       20            0KB/s        0ms
```

Learn more about `qos statistics workload performance show` in the ONTAP command reference.

You can use the `qos statistics workload latency show` command to view detailed latency statistics for QoS workloads.
Learn more about `qos statistics workload latency show` in the ONTAP command reference.

Use adaptive QoS policy groups in ONTAP

You can use an *adaptive QoS* policy group to automatically scale a throughput ceiling or floor to volume size, maintaining the ratio of IOPS to TBs|GBs as the size of the volume changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

Before you begin

- You must be running ONTAP 9.3 or later. Adaptive QoS policy groups are available beginning with ONTAP 9.3.
- You must be a cluster administrator to create a policy group.

About this task

A storage object can be a member of an adaptive policy group or a non-adaptive policy group, but not both. The SVM of the storage object and the policy must be the same. The storage object must be online.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

The ratio of throughput limits to storage object size is determined by the interaction of the following fields:

- `expected-iops` is the minimum expected IOPS per allocated TB|GB.

  > `expected-iops` is guaranteed on AFF platforms only. `expected-iops` is guaranteed for FabricPool only if the tiering policy is set to "none" and no blocks are in the cloud. `expected-iops` is guaranteed for volumes that are not in a SnapMirror synchronous relationship.

- `peak-iops` is the maximum possible IOPS per allocated or used TB|GB.
- `expected-iops-allocation` specifies whether allocated space (the default) or used space is used for expected-iops.

  > `expected-iops-allocation` is available in ONTAP 9.5 and later. It is not supported in ONTAP 9.4 and earlier.

- `peak-iops-allocation` specifies whether allocated space or used space (the default) is used for `peak-iops`.
- `absolute-min-iops` is the absolute minimum number of IOPS. You can use this field with very small storage objects. It overrides both `peak-iops` and/or `expected-iops` when `absolute-min-iops` is greater than the calculated `expected-iops`.

  For example, if you set `expected-iops` to 1,000 IOPS/TB, and the volume size is less than 1 GB, the calculated `expected-iops` will be a fractional IOP. The calculated `peak-iops` will be an even smaller fraction. You can avoid this by setting `absolute-min-iops` to a realistic value.

- `block-size` specifies the application I/O block size. The default is 32K. Valid values are 8K, 16K, 32K, 64K, ANY. ANY means that the block size is not enforced.

Three default adaptive QoS policy groups are available, as shown in the following table. You can apply these policy groups directly to a volume.

Default policy group	Expected IOPS/TB	Peak IOPS/TB	Absolute Min IOPS
`extreme`	6,144	12,288	1000
`performance`	2,048	4,096	500

`value`	128	512	75

You cannot assign a storage object to a policy group if its containing object or its child objects belong to a policy group. The following table lists the restrictions.

If you assign the…	Then you cannot assign…
SVM to a policy group	Any storage objects contained by the SVM to a policy group
Volume to a policy group	The volume's containing SVM or any child LUNs to a policy group
LUN to a policy group	The LUN's containing volume or SVM to a policy group
File to a policy group	The file's containing volume or SVM to a policy group

Steps

1. Create an adaptive QoS policy group:

   `qos adaptive-policy-group create -policy group` *`policy_group`* `-vserver` *`SVM`* `-expected-iops` *`number_of_iops`*`/TB|GB -peak-iops` *`number_of_iops`*`/TB|GB -expected -iops-allocation-space|used-space -peak-iops-allocation allocated-space|used-space -absolute-min-iops` *`number_of_iops`* `-block-size 8K|16K|32K|64K|ANY`

   Learn more about `qos adaptive-policy-group create` in the ONTAP command reference.

   > `-expected-iops-allocation` and `-block-size` is available in ONTAP 9.5 and later. These options are not supported in ONTAP 9.4 and earlier.

   The following command creates adaptive QoS policy group `adpg-app1` with `-expected-iops` set to 300 IOPS/TB, `-peak-iops` set to 1,000 IOPS/TB, `-peak-iops-allocation` set to `used-space`, and `-absolute-min-iops` set to 50 IOPS:

   ```
   cluster1::> qos adaptive-policy-group create -policy group adpg-app1
   -vserver vs2 -expected-iops 300iops/tb -peak-iops 1000iops/TB -peak-iops
   -allocation used-space -absolute-min-iops 50iops
   ```

2. Apply an adaptive QoS policy group to a volume:

   `volume create -vserver SVM -volume` *`volume`* `-aggregate` *`aggregate`* `-size` *`number_of`* `TB|GB -qos-adaptive-policy-group` *`policy_group`*

   Learn more about `volume create` in the ONTAP command reference.

   The following command applies adaptive QoS policy group `adpg-app1` to volume `app1`:

```
cluster1::> volume create -vserver vs1 -volume app1 -aggregate aggr1
-size 2TB -qos-adaptive-policy-group adpg-app1
```

The following commands apply the default adaptive QoS policy group `extreme` to the new volume `app4` and to the existing volume `app5`. The throughput ceiling defined for the policy group applies to volumes `app4` and `app5` individually:

```
cluster1::> volume create -vserver vs4 -volume app4 -aggregate aggr4
-size 2TB -qos-adaptive-policy-group extreme
```

```
cluster1::> volume modify -vserver vs5 -volume app5 -qos-adaptive-policy
-group extreme
```

Set an adaptive policy group template in ONTAP

Beginning with ONTAP 9.13.1, you can enforce throughput floors and ceilings at the SVM level using an adaptive policy group template.

About this task

- The adaptive policy group template is a default policy `apg1`. The policy can be modified at any time. It can only be set with the CLI or ONTAP REST API and can only be applied to existing SVMs.
- The adaptive policy group template only impacts volumes created on or migrated to the SVM after you set the policy. Existing volumes on the SVM retain their existing status.

  If you disable the adaptive policy group template, volumes on the SVM retain their existing policies. Only volumes subsequently created on or migrated to the SVM will be impacted by the disablement.
- You cannot set an adaptive policy group template on an SVM with a QoS policy group.
- Adaptive policy group templates are designed for AFF platforms. An adaptive policy group template can be set on other platforms, but the policy may not enforce a minimum throughput. Similarly, you can add an adaptive policy group template to an SVM in a FabricPool aggregate or in an aggregate that does not support a minimum throughput; however, the throughput floor will not be enforced.
- If the SVM is in a MetroCluster configuration or an SnapMirror relationship, the adaptive policy group template will be enforced on the mirrored SVM.

Steps

1. Modify the SVM to apply the adaptive policy group template:
   `vserver modify -qos-adaptive-policy-group-template apg1`
2. Confirm the policy was set:
   `vserver show -fields qos-adaptive-policy-group`

Monitor cluster performance with ONTAP Unified Manager

With Active IQ Unified Manager, you can maximize availability and maintain control of your NetApp AFF and FAS storage infrastructure for improved scalability, supportability, performance, and security.

Active IQ Unified Manager continuously monitors system health and send alerts, so your organization can free up IT staff resources. You can instantly view storage status from a single dashboard and quickly address issues through recommended actions.

Data management is simplified because you can discover, monitor, and receive notifications to proactively manage storage and quickly resolve issues. Admin efficiency is improved because you can monitor petabytes of data from a single dashboard and manage your data at scale.

With Active IQ Unified Manager, you can keep pace with fluctuating business demands, optimizing performance using performance data and advanced analytics. The reporting capabilities allow you to access standard reports or create custom operational reports to meet the specific needs of your business.

Monitor cluster performance with ONTAP Data Infrastructure Insights

NetApp Data Infrastructure Insights is a monitoring tool that gives you visibility into your complete infrastructure. With Data Infrastructure Insights, you can monitor, troubleshoot, and optimize all your resources including your public clouds and your private data centers.

Monitor, troubleshoot, and optimize all your resources

Data Infrastructure Insights helps you significantly reduce the time to resolve issues and prevent them from impacting end users. It also helps you reduce cloud infrastructure costs. Your exposure to insider threats is reduced by protecting your data with actionable intelligence.

Data Infrastructure Insights gives you visibility to your entire hybrid infrastructure in one place—from the public cloud to your data center. You can instantly create relevant dashboards that can be customized to your specific needs. You can also create targeted and conditional alerts that are specific and relevant to your organization’s needs.

Advanced anomaly detection helps you proactively fix issues before they arise. You can view resource contention and degradation automatically to quickly restore impacted workloads. Troubleshooting goes more quickly with the automatically built hierarchy of relationships between the different components in your stack.

You can identify unused or abandoned resources across your environment, which helps you discover opportunities to right-size the infrastructure and optimize your entire spend.

Data Infrastructure Insights visualizes your system topology to gain an understanding of your Kubernetes architecture. You can monitor the health of your Kubernetes clusters, including which nodes are in trouble, and zoom in when you see a problem.

Data Infrastructure Insights helps you protect organizational data from being misused by malicious or compromised users through advanced machine learning and anomaly detection that gives you actionable intelligence on insider threats.

Data Infrastructure Insights helps you to visualize Kubernetes metrics so you can fully understand the relations between your pods, nodes, and clusters. You're able to assess the health of a cluster or a working pod, as well as the load it is currently processing—enabling you to take command of your K8S cluster and to control both the health and the cost of your deployment.

Audit logging

Learn about ONTAP audit logging implementation

Management activities recorded in the audit log are included in standard AutoSupport reports, and certain logging activities are included in EMS messages. You can also forward the audit log to destinations that you specify, and you can display audit log files by using the ONTAP CLI or a web browser.

Beginning with ONTAP 9.11.1, you can display audit log contents using System Manager.

Beginning with ONTAP 9.12.1, ONTAP provides tampering alerts for audit logs. ONTAP runs a daily background job to check for tampering of audit.log files and sends an EMS alert if it finds any log files that have been changed or tampered with.

Beginning with ONTAP 9.17.1, and with ONTAP 9.16.1 P4 and later 9.16.1 patch releases, remote management activities initiated from a peered cluster using cross-cluster operations can also be logged. These activities include user-driven and internal operations that originate from another cluster.

Management activities logged in ONTAP

ONTAP logs management activities that are performed on a cluster, such as what request was issued, the user who triggered the request, the user's access method, and the time of the request.

Management activities can be one of the following types:

- **SET requests**:
  - These requests typically apply to non-display commands or operations.
  - These requests are issued when you run a `create`, `modify`, or `delete` command, for instance.
  - SET requests are logged by default.
- **GET requests**:
  - These requests retrieve information and display it in the management interface.
  - These requests are issued when you run a `show` command, for instance.
  - GET requests are not logged by default, but you can control whether GET requests sent from the

ONTAP CLI (`-cliget`), from the ONTAP API (`-ontapiget`), or from the ONTAP REST API (`-httpget`) are logged in the file.

Audit log recording and rotation

ONTAP records management activities in the `/mroot/etc/log/mlog/audit.log` file of a node. Commands from the three shells for CLI commands: the clustershell, the nodeshell, and the non-interactive systemshell as well as API commands are logged here. Interactive systemshell commands are not logged. Audit logs include timestamps to show whether all nodes in a cluster are synchronized.

The `audit.log` file is sent by the AutoSupport tool to the specified recipients. You can also forward the content securely to external destinations that you specify; for example, a Splunk or a syslog server.

The `audit.log` file is rotated daily. The rotation also occurs when it reaches 100 MB in size, and the previous 48 copies are preserved (with a maximum total of 49 files). When the audit file performs its daily rotation, no EMS message is generated. If the audit file rotates because its file size limit is exceeded, an EMS message is generated.

When enabling GET auditing, consider configuring log forwarding to avoid data loss due to rapid log rotation. For more information, see the following Knowledge Base article:
Enabling audit log forwarding.

Learn about changes to ONTAP audit logging

Beginning with ONTAP 9, the `command-history.log` file is replaced by `audit.log`, and the `mgwd.log` file no longer contains audit information. If you are upgrading to ONTAP 9, you should review any scripts or tools that refer to the legacy files and their contents.

After upgrade to ONTAP 9, existing `command-history.log` files are preserved. They are rotated out (deleted) as new `audit.log` files are rotated in (created).

Tools and scripts that check the `command-history.log` file might continue to work, because a soft link from `command-history.log` to `audit.log` is created at upgrade. However, tools and scripts that check the `mgwd.log` file will fail, because that file no longer contains audit information.

In addition, audit logs in ONTAP 9 and later no longer include the following entries because they are not considered useful and cause unnecessary logging activity:

- Internal commands run by ONTAP (that is, where username=root)
- Command aliases (separately from the command they point to)

Beginning with ONTAP 9, you can transmit the audit logs securely to external destinations using the TCP and TLS protocols.

Display ONTAP audit log contents

You can display the contents of the cluster's `/mroot/etc/log/mlog/audit.log` files by using the ONTAP CLI, System Manager, or a web browser.

The cluster's log file entries include the following:

Time

The log entry timestamp.

Application

The application used to connect to the cluster. Examples of possible values are `internal`, `console`, `ssh`, `http`, `ontapi`, `snmp`, `rsh`, `telnet`, and `service-processor`.

User

The username of the remote user.

State

The current state of the audit request, which could be `success`, `pending`, or `error`.

Message

An optional field that might contain error or additional information about the status of a command.

Session ID

The session ID on which the request is received. Each SSH *session* is assigned a session ID, while each HTTP, ONTAPI, or SNMP *request* is assigned a unique session ID.

Storage VM

The SVM through which the user connected.

Scope

Displays `svm` when the request is on a data storage VM; otherwise displays `cluster`.

Command ID

The ID for each command received on a CLI session. This enables you to correlate a request and response. ZAPI, HTTP, and SNMP requests do not have command IDs.

You can display the cluster's log entries from the ONTAP CLI, from a web browser, and beginning with ONTAP 9.11.1, from System Manager.

System Manager

- To display the inventory, select **Events & Jobs > Audit Logs**.
  Each column has controls to filter, sort, search, show, and inventory categories. The inventory details can be downloaded as an Excel workbook.
- To set filters, click the **Filter** button on the upper right side, then select the desired fields.
  You can also view all the commands executed in the session in which a failure occurred by clicking on the Session ID link.

CLI

To display audit entries merged from multiple nodes in the cluster, enter:

```
security audit log show <[parameters]>
```

You can use the `security audit log show` command to display audit entries for individual nodes or merged from multiple nodes in the cluster. You can also display the content of the `/mroot/etc/log/mlog` directory on a single node by using a web browser.
Learn more about `security audit log show` in the ONTAP command reference.

Web browser

You can display the content of the `/mroot/etc/log/mlog` directory on a single node by using a web browser. Learn about how to access a node's log, core dump, and MIB files by using a web browser.

Manage ONTAP audit GET request settings

While SET requests are logged by default, GET requests are not. However, you can control whether GET requests sent from ONTAP HTML (`-httpget`), the ONTAP CLI (`-cliget`), or from the ONTAP APIs (`-ontapiget`) are logged in the file.

You can modify audit logging settings from the ONTAP CLI, and beginning with ONTAP 9.11.1, from System Manager.

System Manager

1. Select **Events & Jobs > Audit Logs**.
2. Click in the upper-right corner, then choose the requests to add or remove.

CLI

- To specify that GET requests from the ONTAP CLI or APIs should be recorded in the audit log (the audit.log file), in addition to default set requests, enter:
  ```
  security audit modify [-cliget {on|off}][-httpget {on|off}][-ontapiget {on|off}]
  ```
- To display the current settings, enter:
  ```
  security audit show
  ```

Learn more about `security audit show` in the ONTAP command reference.

Enable ONTAP cross-cluster audits

Beginning with ONTAP 9.17.1, and with ONTAP 9.16.1 P4 and later 9.16.1 patch releases, you can enable cross-cluster auditing in ONTAP to log operations initiated from a peered cluster. This remote auditing is particularly valuable in environments where multiple ONTAP clusters interact, providing traceability and accountability of remote actions.

Cross-cluster auditing can distinguish between user-initiated GET (read) or SET (create/modify/remove) operations. Only user-initiated SET operations are audited on destination clusters by default. Any request that reads data, such as a GET or `show` command in the CLI, is not audited by default regardless of whether the request is cross cluster.

Before you begin

- You must have `advanced` level permissions
- The cluster must be peered with another cluster, and both clusters must be running ONTAP 9.16.1 P4 or later.

> In environments where some but not all nodes are upgraded to ONTAP 9.16.1 P4 or later, audit logging occurs only on nodes running the upgraded version. It's recommended to upgrade all nodes to a supported version to ensure consistent auditing behavior.

Enable or disable cross-cluster auditing

Steps

1. Enable (or disable) cross-cluster auditing on the cluster by setting the `cluster-peer` parameter to `on` or `off`:

```
security audit modify -cluster-peer {on|off}
```

2. Confirm that the cluster peer setting is enabled or disabled by checking the current audit state:

```
security audit show
```

Response:

```
    Audit Setting State
    ------------- -----
         CLI GET: off
        HTTP GET: off
      ONTAPI GET: off
    Cluster Peer: on
```

Effects of enabling GET auditing

Beginning with ONTAP 9.17.1, if you enable CLI, HTTP, ONTAPI GET auditing on a peered cluster, you also enable auditing of cross-cluster user-initiated GET requests. In earlier ONTAP versions, GET auditing only applied to requests on a local cluster. With ONTAP 9.17.1, if you enable GET auditing with the `cluster-peer` option set to `on`, both local cluster and cross-cluster requests will be audited.

Manage ONTAP audit log destinations

You can forward the audit log to a maximum of 10 destinations. For example, you can forward the log to a Splunk or syslog server for monitoring, analysis, or backup purposes.

About this task

To configure forwarding, you must provide the IP address of the syslog or Splunk host, its port number, a transmission protocol, and the syslog facility to use for the forwarded logs. Learn about syslog facilities.

You can select one of the following transmission values using the `-protocol` parameter:

UDP Unencrypted
User Datagram Protocol with no security (default)

TCP Unencrypted
Transmission Control Protocol with no security

TCP Encrypted
Transmission Control Protocol with Transport Layer Security (TLS)
A **Verify server** option is available when the TCP Encrypted protocol is selected.

The default port is 514 for UDP and 6514 for TCP, but you can designate any port that meets the needs of your network.

You can select one of the following message formats using the `-message-format` command:

legacy-netapp
A variation of the RFC-3164 Syslog format (format: <PRIVAL>TIMESTAMP HOSTNAME: MSG)

rfc-5424
Syslog format as per RFC-5424 (format: <PRIVAL>VERSION TIMESTAMP HOSTNAME: MSG)

You can forward audit logs from the ONTAP CLI, and beginning with ONTAP 9.11.1, from System Manager.

System Manager

- To display audit log destinations, select **Cluster >Settings**.
  A count of log destinations is shown in the **Notification Management tile**. Click ⋮ to show details.
- To add, modify, or delete audit log destinations, select **Events & Jobs > Audit Logs**, then click **Manage Audit Destinations** in the upper right of the screen.
  Click + Add, or click ⋮ in the **Host Address** column to edit or delete entries.

CLI

1. For each destination that you want to forward the audit log to, specify the destination IP address or host name and any security options.

```
cluster1::> cluster log-forwarding create -destination
192.168.123.96
-port 514 -facility user

cluster1::> cluster log-forwarding create -destination
192.168.123.98
-port 6514 -protocol tcp-encrypted -facility user
```

   - If the `cluster log-forwarding create` command cannot ping the destination host to verify connectivity, the command fails with an error. Although not recommended, using the `-force` parameter with the command bypasses the connectivity verification.
   - When you set the `-verify-server` parameter to `true`, the identity of the log forwarding destination is verified by validating its certificate. You can set the value to `true` only when you select the `tcp-encrypted` value in the `-protocol` field.

2. Verify that the destination records are correct by using the `cluster log-forwarding show` command.

```
cluster1::> cluster log-forwarding show

                                                 Verify Syslog
Destination Host          Port   Protocol        Server Facility
------------------------- ------ --------        ------ --------
192.168.123.96            514    udp-unencrypted false  user
192.168.123.98            6514   tcp-encrypted   true   user
2 entries were displayed.
```

AutoSupport

Learn about AutoSupport

Learn about ONTAP AutoSupport

AutoSupport is a mechanism that proactively monitors the health of your system and automatically sends messages to NetApp technical support, your internal support organization, and a support partner. Although AutoSupport messages to technical support are enabled by default, you must set the correct options and have a valid mail host to have messages sent to your internal support organization.

Only the cluster administrator can perform AutoSupport management. The storage virtual machine (SVM) administrator has no access to AutoSupport.

AutoSupport is enabled by default when you configure your storage system for the first time. AutoSupport begins sending messages to technical support 24 hours after AutoSupport is enabled. You can shorten the 24-hour period by upgrading or reverting the system, modifying the AutoSupport configuration, or changing the system time to be something other than a 24-hour period.

> You can disable AutoSupport at any time, but you should leave it enabled. Enabling AutoSupport can significantly help speed problem determination and resolution should a problem occur on your storage system. By default, the system collects AutoSupport information and stores it locally, even if you disable AutoSupport.

For more information about AutoSupport, see the NetApp Support Site.

Learn about Digital Advisor and ONTAP AutoSupport

The AutoSupport component of ONTAP collects telemetry and sends it for analysis. Digital Advisor analyzes the data from AutoSupport and provides proactive care and optimization. Using artificial intelligence, Digital Advisor can identify potential problems and help you resolve them before they impact your business.

Digital Advisor enables you to optimize your data infrastructure across your global hybrid cloud by delivering actionable predictive analytics and proactive support through a cloud-based portal and mobile app. Data-driven insights and recommendations from Digital Advisor are available to all NetApp customers with an active SupportEdge contract (features vary by product and support tier).

Here are some things you can do with Digital Advisor:

- Plan upgrades. Digital Advisor identifies issues in your environment that can be resolved by upgrading to a newer version of ONTAP and the Upgrade Advisor component helps you plan for a successful upgrade.
- View system wellness. Your Digital Advisor dashboard reports any issues with wellness and helps you correct those issues. Monitor system capacity to make sure you never run out of storage space. View support cases for your system.

- Manage performance. Digital Advisor shows system performance over a longer period than you can see in System Manager. Identify configuration and system issues that are impacting your performance.
- Maximize efficiency. View storage efficiency metrics and identify ways to store more data in less space.
- View inventory and configuration. Digital Advisor displays complete inventory and software and hardware configuration information. See when service contracts are expiring and renew them to ensure you remain supported.

SupportEdge Services

Learn about when and where ONTAP AutoSupport messages are sent

AutoSupport sends messages to different recipients, depending on the type of message. Learning when and where AutoSupport sends messages can help you understand messages that you receive through email or view on the Digital Advisor web site.

Unless specified otherwise, settings in the following tables are parameters of the `system node autosupport modify` command.

Event-triggered messages

When events occur on the system that require corrective action, AutoSupport automatically sends an event-triggered message.

When the message is sent	Where the message is sent
AutoSupport responds to a trigger event in the EMS	Addresses specified in `-to` and `-noteto`. (Only critical, service-affecting events are sent.) Addresses specified in `-partner-address` Technical support, if `-support` is set to `enable`

Scheduled messages

AutoSupport automatically sends several messages on a regular schedule.

When the message is sent	Where the message is sent
Daily (by default, sent between 12:00 a.m. and 1:00 a.m. as a log message)	Addresses specified in `-partner-address` Technical support, if `-support` is set to `enable`
Daily (by default, sent between 12:00 a.m. and 1:00 a.m. as a performance message), if the `-perf` parameter is set to `true`	Addresses specified in -partner-address`  Technical support, if `-support` is set to `enable`

When the message is sent	Where the message is sent
Weekly (by default, sent Sunday between 12:00 a.m. and 1:00 a.m.)	Addresses specified in `-partner-address` Technical support, if `-support` is set to `enable`

Manually triggered messages

You can manually initiate or resend an AutoSupport message.

When the message is sent	Where the message is sent
You manually initiate a message using the `system node autosupport invoke` command	If a URI is specified using the `-uri` parameter in the `system node autosupport invoke` command, the message is sent to that URI. If `-uri` is omitted, the message is sent to the addresses specified in `-to` and `-partner-address`. The message is also sent to technical support if `-support` is set to `enable`.
You manually initiate a message using the `system node autosupport invoke-core-upload` command	If a URI is specified using the `-uri` parameter in the `system node autosupport invoke-core-upload` command, the message is sent to that URI, and the core dump file is uploaded to the URI. If `-uri` is omitted in the `system node autosupport invoke-core-upload` command, the message is sent to technical support, and the core dump file is uploaded to the technical support site. Both scenarios require that `-support` is set to `enable` and `-transport` is set to `https` or `http`. Due to the large size of core dump files, the message is not sent to the addresses specified in the `-to` and `-partner-addresses` parameters.

When the message is sent	Where the message is sent
You manually initiate a message using the `system node autosupport invoke-performance-archive` command	If a URI is specified using the `-uri` parameter in the `system node autosupport invoke-performance-archive` command, the message is sent to that URI, and the performance archive file is uploaded to the URI. If `-uri` is omitted in the `system node autosupport invoke-performance-archive`, the message is sent to technical support, and the performance archive file is uploaded to the technical support site. Both scenarios require that `-support` is set to `enable` and `-transport` is set to `https` or `http`. Due to the large size of performance archive files, the message is not sent to the addresses specified in the `-to` and `-partner-addresses` parameters.
You manually resend a past message using the `system node autosupport history retransmit` command	Only to the URI that you specify in the `-uri` parameter of the `system node autosupport history retransmit` command

Messages triggered by technical support

Technical support can request messages from AutoSupport using the AutoSupport OnDemand feature.

When the message is sent	Where the message is sent
When AutoSupport obtains delivery instructions to generate new AutoSupport messages	Addresses specified in `-partner-address` Technical support, if `-support` is set to `enable` and `-transport` is set to `https`
When AutoSupport obtains delivery instructions to resend past AutoSupport messages	Technical support, if `-support` is set to `enable` and `-transport` is set to `https`
When AutoSupport obtains delivery instructions to generate new AutoSupport messages that upload core dump or performance archive files	Technical support, if `-support` is set to `enable` and `-transport` is set to `https`. The core dump or performance archive file is uploaded to the technical support site.

Learn about ONTAP AutoSupport event-triggered messages

AutoSupport creates event-triggered AutoSupport messages when the EMS processes a trigger event. An event-triggered AutoSupport message alerts recipients to problems that require corrective action and contains only information that is relevant to the problem. You can customize what content to include and who receives the messages.

AutoSupport uses the following process to create and send event-triggered AutoSupport messages:

1. When the EMS processes a trigger event, EMS sends AutoSupport a request.

   A trigger event is an EMS event with an AutoSupport destination and a name that begins with a `callhome.` prefix.

2. AutoSupport creates an event-triggered AutoSupport message.

   AutoSupport collects basic and troubleshooting information from subsystems that are associated with the trigger to create a message that includes only information that is relevant to the trigger event.

   A default set of subsystems is associated with each trigger. However, you can choose to associate additional subsystems with a trigger by using the `system node autosupport trigger modify` command.

3. AutoSupport sends the event-triggered AutoSupport message to the recipients defined by the `system node autosupport modify` command with the `-to`, `-noteto`, `-partner-address`, and `-support` parameters.

   You can enable and disable delivery of AutoSupport messages for specific triggers by using the `system node autosupport trigger modify` command with the `-to` and `-noteto` parameters.

Example of data sent for a specific event

The `storage shelf PSU failed` EMS event triggers a message that contains basic data from the Mandatory, Log Files, Storage, RAID, HA, Platform, and Networking subsystems and troubleshooting data from the Mandatory, Log Files, and Storage subsystems.

You decide that you want to include data about NFS in any AutoSupport messages sent in response to a future `storage shelf PSU failed` event. You enter the following command to enable troubleshooting-level data for NFS for the `callhome.shlf.ps.fault` event:

```
        cluster1::\>
        system node autosupport trigger modify -node node1 -autosupport
-message shlf.ps.fault -troubleshooting-additional nfs
```

Note that the `callhome.` prefix is dropped from the `callhome.shlf.ps.fault` event when you use the `system node autosupport trigger` commands, or when referenced by AutoSupport and EMS events in the CLI.

Types of ONTAP AutoSupport messages and their content

AutoSupport messages contain status information about supported subsystems. Learning what AutoSupport messages contain can help you interpret or respond to messages that you receive in email or view on the Digital Advisor web site.

Type of message	Type of data the message contains
Event-triggered	Files containing context-sensitive data about the specific subsystem where the event occurred
Daily	Log files
Performance	Performance data sampled during the previous 24 hours
Weekly	Configuration and status data
Triggered by the `system node autosupport invoke` command	Depends on the value specified in the `-type` parameter: • `test` sends a user-triggered message with some basic data. This message also triggers an automated email response from technical support to any specified email addresses, using the `-to` option, so that you can confirm that AutoSupport messages are being received. • `performance` sends performance data. • `all` sends a user-triggered message with a complete set of data similar to the weekly message, including troubleshooting data from each subsystem. Technical support typically requests this message.
Triggered by the `system node autosupport invoke-core-upload` command	Core dump files for a node
Triggered by the `system node autosupport invoke-performance-archive` command	Performance archive files for a specified period of time

Type of message	Type of data the message contains
Triggered by AutoSupport OnDemand	AutoSupport OnDemand can request new messages or past messages: • New messages, depending on the type of AutoSupport collection, can be `test`, `all`, or `performance`. • Past messages depend on the type of message that is resent. AutoSupport OnDemand can request new messages that upload the following files to the NetApp Support Site at mysupport.netapp.com: • Core dump • Performance archive

View ONTAP AutoSupport subsystems

Each subsystem provides basic and troubleshooting information that AutoSupport uses for its messages. Each subsystem is also associated with trigger events that allow AutoSupport to collect from subsystems only information that is relevant to the trigger event.

AutoSupport collects context-sensitive content.

Steps

1. View information about subsystems and trigger events:

```
system node autosupport trigger show
```

Learn about ONTAP AutoSupport size and time budgets

AutoSupport collects information, organized by subsystem, and enforces a size and time budget on content for each subsystem. As storage systems grow, AutoSupport budgets provide control over the AutoSupport payload, which in turn provides scalable delivery of AutoSupport data.

AutoSupport stops collecting information and truncates the AutoSupport content if the subsystem content exceeds its size or time budget. If the content cannot be truncated easily (for example, binary files), AutoSupport omits the content.

You should modify the default size and time budgets only if asked to do so by NetApp Support. You can also review the default size and time budgets of the subsystems by using the `autosupport manifest show` command.

Learn about files sent in event-triggered ONTAP AutoSupport messages

Event-triggered AutoSupport messages only contain basic and troubleshooting information from subsystems that are associated with the event that caused AutoSupport to generate the message. The specific data helps NetApp support and support partners troubleshoot the problem.

AutoSupport uses the following criteria to control content in event-triggered AutoSupport messages:

- Which subsystems are included

  Data is grouped into subsystems, including common subsystems, such as Log Files, and specific subsystems, such as RAID. Each event triggers a message that contains only the data from specific subsystems.

- The detail level of each included subsystem

  Data for each included subsystem is provided at a basic or troubleshooting level.

You can view all possible events and determine which subsystems are included in messages about each event using the `system node autosupport trigger show` command with the `-instance` parameter.

In addition to the subsystems that are included by default for each event, you can add additional subsystems at either a basic or a troubleshooting level using the `system node autosupport trigger modify` command.

Log files sent in AutoSupport messages

AutoSupport messages can contain several key log files that enable technical support staff to review recent system activity.

All types of AutoSupport messages might include the following log files when the Log Files subsystem is enabled:

Log file	Amount of data included from the file
• Log files from the `/mroot/etc/log/mlog/` directory • The MESSAGES log file	Only new lines added to the logs since the last AutoSupport message up to a specified maximum. This ensures that AutoSupport messages have unique, relevant—not overlapping—data. (Log files from partners are the exception; for partners, the maximum allowed data is included.)
• Log files from the `/mroot/etc/log/shelflog/` directory • Log files from the `/mroot/etc/log/acp/` directory • Event Management System (EMS) log data	The most recent lines of data up to a specified maximum.

The content of AutoSupport messages can change between releases of ONTAP.

Files sent in weekly AutoSupport messages

Weekly AutoSupport messages contain additional configuration and status data that is useful to track changes in your system over time.

The following information is sent in weekly AutoSupport messages:

- Basic information about every subsystem
- Contents of selected `/mroot/etc` directory files
- Log files
- Output of commands that provide system information
- Additional information, including replicated database (RDB) information, service statistics, and more

Learn about how ONTAP AutoSupport OnDemand obtains delivery instructions from technical support

AutoSupport OnDemand periodically communicates with technical support to obtain delivery instructions for sending, resending, and declining AutoSupport messages as well as uploading large files to the NetApp support site. AutoSupport OnDemand enables AutoSupport messages to be sent on-demand instead of waiting for the weekly AutoSupport job to run.

AutoSupport OnDemand consists of the following components:

- AutoSupport OnDemand client that runs on each node
- AutoSupport OnDemand service that resides in technical support

The AutoSupport OnDemand client periodically polls the AutoSupport OnDemand service to obtain delivery instructions from technical support. For example, technical support can use the AutoSupport OnDemand service to request that a new AutoSupport message be generated. When the AutoSupport OnDemand client polls the AutoSupport OnDemand service, the client obtains the delivery instructions and sends the new AutoSupport message on-demand as requested.

AutoSupport OnDemand is enabled by default. However, AutoSupport OnDemand relies on some AutoSupport settings to continue communicating with technical support. AutoSupport OnDemand automatically communicates with technical support when the following requirements are met:

- AutoSupport is enabled.
- AutoSupport is configured to send messages to technical support.
- AutoSupport is configured to use the HTTPS transport protocol.

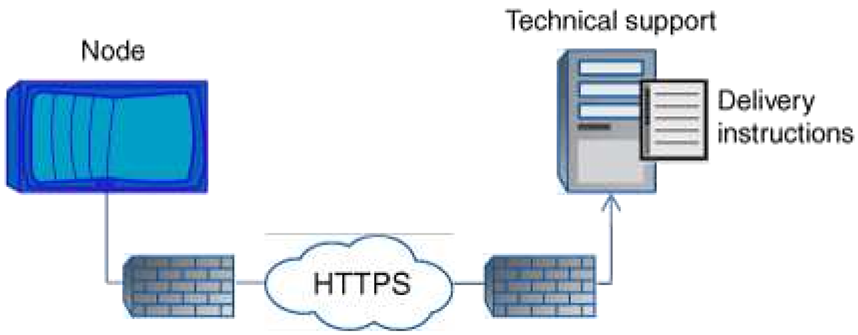
The AutoSupport OnDemand client sends HTTPS requests to the same technical support location to which AutoSupport messages are sent. The AutoSupport OnDemand client does not accept incoming connections.

> AutoSupport OnDemand uses the “autosupport” user account to communicate with technical support. ONTAP prevents you from deleting this account.

If you want to disable AutoSupport OnDemand, but keep AutoSupport enabled, use the command `system node autosupport modify -ondemand-state disable`.
Learn more about `system node autosupport modify -ondemand-state disable` in the ONTAP

command reference.

The following illustration shows how AutoSupport OnDemand sends HTTPS requests to technical support to obtain delivery instructions.



The delivery instructions can include requests for AutoSupport to do the following:

- Generate new AutoSupport messages.

  Technical support might request new AutoSupport messages to help triage issues.

- Generate new AutoSupport messages that upload core dump files or performance archive files to the NetApp support site.

  Technical support might request core dump or performance archive files to help triage issues.

- Retransmit previously generated AutoSupport messages.

  This request automatically happens if a message was not received due to a delivery failure.

- Disable delivery of AutoSupport messages for specific trigger events.

  Technical support might disable delivery of data that is not used.

Learn about the structure of ONTAP AutoSupport messages sent by email

When an AutoSupport message is sent by email, the message has a standard subject, a brief body, and a large attachment in 7z file format that contains the data.

> ⓘ If AutoSupport is configured to hide private data, certain information, such as the hostname, is omitted or masked in the header, subject, body, and attachments.

Subject

The subject line of messages sent by the AutoSupport mechanism contains a text string that identifies the reason for the notification. The format of the subject line is as follows:

HA Group Notification from *System_Name* (*Message*) *Severity*

- *System_Name* is either the hostname or the system ID, depending on the AutoSupport configuration

Body

The body of the AutoSupport message contains the following information:

- Date and timestamp of the message
- Version of ONTAP on the node that generated the message
- System ID, serial number, and hostname of the node that generated the message
- AutoSupport sequence number
- SNMP contact name and location, if specified
- System ID and hostname of the HA partnernode

Attached files

The key information in an AutoSupport message is contained in files that are compressed into a 7z file called `body.7z` and attached to the message.

The files contained in the attachment are specific to the type of AutoSupport message.

Learn about ONTAP AutoSupport severity types

AutoSupport messages have severity types that help you understand the purpose of each message—for example, to draw immediate attention to an emergency problem, or only to provide information.

Messages have one of the following severities:

- **Alert**: Alert messages indicate that a next-higher level event might occur if you do not take some action.

  You must take an action against alert messages within 24 hours.

- **Emergency**: Emergency messages are displayed when a disruption has occurred.

  You must take an action against emergency messages immediately.

- **Error**: Error conditions indicate what might happen if you ignore.
- **Notice**: Normal but significant condition.
- **Info**: Informational message provides details about the issue, which you can ignore.
- **Debug**: Debug-level messages provide instructions you should perform.

If your internal support organization receives AutoSupport messages through email, the severity appears in the subject line of the email message.

Get ONTAP AutoSupport message descriptions

The descriptions of the AutoSupport messages that you receive are available through the ONTAP Syslog Translator.

Steps

1. Go to the Syslog Translator.
2. In the **Release** field, enter the the version of ONTAP you are using. In the **Search String** field, enter

"callhome". Select **Translate**.

3. The Syslog Translator will alphabetically list all events that match the message string you entered.

Commands for managing ONTAP AutoSupport

You use the `system node autosupport` commands to change or view AutoSupport configuration, display information about previous AutoSupport messages, and send, resend or cancel an AutoSupport message.

Configure AutoSupport

If you want to…	Use this command…
Control whether any AutoSupport messages are sent	`system node autosupport modify` with the `-state` parameter
Control whether AutoSupport messages are sent to technical support	`system node autosupport modify` with the `-support` parameter
Set up AutoSupport or modify the configuration of AutoSupport	`system node autosupport modify`
Enable and disable AutoSupport messages to your internal support organization for individual trigger events, and specify additional subsystem reports to include in messages sent in response to individual trigger events	`system node autosupport trigger modify`

Display information about the AutoSupport configuration

If you want to…	Use this command…
Display the AutoSupport configuration	`system node autosupport show` with the `-node` parameter
View a summary of all addresses and URLs that receive AutoSupport messages	`system node autosupport destinations show`
Display which AutoSupport messages are sent to your internal support organization for individual trigger events	`system node autosupport trigger show`
Display status of AutoSupport configuration as well as delivery to various destinations	`system node autosupport check show`
Display detailed status of AutoSupport configuration as well as delivery to various destinations	`system node autosupport check show-details`

Display information about past AutoSupport messages

If you want to…	Use this command…
Display information about one or more of the 50 most recent AutoSupport messages	`system node autosupport history show`
Display information about recent AutoSupport messages generated to upload core dump or performance archive files to the technical support site or a specified URI	`system node autosupport history show-upload-details`
View the information in the AutoSupport messages including the name and size of each file collected for the message along with any errors	`system node autosupport manifest show`

Send, resend, or cancel AutoSupport messages

If you want to…	Use this command…
Retransmit a locally stored AutoSupport message, identified by its AutoSupport sequence number ⓘ If you retransmit an AutoSupport message, and if support already received that message, the support system will not create a duplicate case. If, on the other hand, support did not receive that message, then the AutoSupport system will analyze the message and create a case, if necessary.	`system node autosupport history retransmit`
Generate and send an AutoSupport message—for example, for testing purposes	`system node autosupport invoke` ⓘ Use the `-force` parameter to send a message even if AutoSupport is disabled. Use the `-uri` parameter to send the message to the destination you specify instead of the configured destination.
Cancel an AutoSupport message	`system node autosupport history cancel`

Learn more about `system node autosupport` in the ONTAP command reference.

Related information

ONTAP command reference

Learn about information included in the ONTAP AutoSupport manifest

The AutoSupport manifest provides you with a detailed view of the files collected for each AutoSupport message. The AutoSupport manifest also includes information about collection errors when AutoSupport cannot collect the files it needs.

The AutoSupport manifest includes the following information:

- Sequence number of the AutoSupport message
- Which files AutoSupport included in the AutoSupport message
- Size of each file, in bytes
- Status of the AutoSupport manifest collection
- Error description, if AutoSupport failed to collect one or more files

You can view the AutoSupport manifest by using the `system node autosupport manifest show` command.

The AutoSupport manifest is included with every AutoSupport message and presented in XML format, which means that you can either use a generic XML viewer to read it or view it using the Digital Advisor portal.

Plan

Prepare to use ONTAP AutoSupport

You can configure an ONTAP cluster to deliver AutoSupport messages to NetApp. As part of this, you can also send a copy of the messages to local email addresses, typically within your organization. You should prepare to configure AutoSupport by reviewing the available options.

Deliver AutoSupport messages to NetApp

AutoSupport messages can be delivered to NetApp using either HTTPS or SMTP protocols. Beginning with ONTAP 9.15.1, you can also use TLS with SMTP.

> Use HTTPS whenever possible for communication with AutoSupport OnDemand and uploads of large files.

Also note the following:

- Only one delivery channel to NetApp can be configured for the AutoSupport messages. You cannot use two protocols to deliver AutoSupport messages to NetApp.
- AutoSupport limits the maximum file size for each protocol. If the size of an AutoSupport message exceeds the configured limit, AutoSupport delivers as much of the message as possible but truncation will occur.
- You can change the maximum file size if needed. Learn more about `system node autosupport modify` in the ONTAP command reference.
- Both protocols can be transported over IPv4 or IPv6 based on the address family to which the name resolves.
- The TCP connection established by ONTAP to send AutoSupport messages is temporary and short-lived.

HTTPS

This provides the most robust features. Note the following:

- AutoSupport OnDemand and the transfer of large files are supported.
- An HTTPS PUT request is attempted first. If the request fails during transmission, the request restarts where it stopped.
- If the server does not support PUT, the HTTPS POST method is used instead.
- The default limit for HTTPS transfers is 50 MB.
- The HTTPS protocol uses port 443.

SMTP

As a general rule, you should use SMTP only if HTTPS is not allowed or is unsupported. Note the following:

- AutoSupport OnDemand and transfers of large files are not supported.
- If SMTP sign-in credentials are configured, they are sent unencrypted and in the clear.
- The default limit for transfers is 5 MB.
- The unsecured SMTP protocol uses port 25.

Improve SMTP security with TLS

When using SMTP, all traffic is unencrypted and can be easily intercepted and read. Beginning with ONTAP 9.15.1 you can also use TLS with SMTP (SMTPS). In this case, *explicit TLS* is used which activates the secure channel after the TCP connection is established.

The following port is typically used for SMTPS: Port 587

Additional configuration considerations

There are a few additional considerations when configuring AutoSupport.

For more information about the commands relevant to these considerations, refer to Set up AutoSupport.

Send a local copy using email

Regardless of the protocol used to deliver AutoSupport messages to NetApp, you can also send a copy of each message to one or more local email addresses. For example, you might send messages to your internal support organization or a partner organization.

> ⓘ If you deliver messages to NetApp using SMTP (or SMTPS) and you also send local email copies of those messages, the same email server configuration is used.

HTTP proxy

Depending on your network configuration, the HTTPS protocol might require additional configuration of a proxy URL. If HTTPS is used to send AutoSupport messages to technical support and you have a proxy, you must identify the URL for the proxy. If the proxy uses a port other than the default (port 3128), you can specify the port for that proxy. You can also optionally specify a user name and password for proxy authentication.

Install the server certificate

With TLS (HTTPS or SMTPS), the certificate downloaded from the server is validated by ONTAP based on the root CA certificate. Before using HTTPS or SMTPS, you need to make sure the root certificate is installed in ONTAP and that ONTAP can validate the server certificate. This validation is performed based on the CA that signed the server certificate.

ONTAP includes a large number of pre-installed root CA certificates. In many cases, the certificate for your server will be immediately recognized by ONTAP without additional configuration. Depending on how the server certificate was signed, you might need to install a root CA certificate and any intermediate certificates.

Use the following procedure to install the certificate, if needed. You should install all required certificates at the cluster level.

Example 37. Steps

System Manager

1. In System Manager, select **Cluster** > **Settings**.
2. Scroll down to the **Security** section.
3. Select → next to **Certificates**.
4. Under the **Trusted certificate authorities** tab click **Add**.
5. Click **Import** and select the certificate file.
6. Complete the configuration parameters for your environment.
7. Click **Add**.

CLI

1. Begin the installation:

   ```
   security certificate install -type server-ca
   ```

   Learn more about `security certificate install` in the ONTAP command reference.

2. Look for the following console message:

   ```
   Please enter Certificate: Press <Enter> when done
   ```

3. Open the certificate file with a text editor.
4. Copy the entire certificate including the following lines:

   ```
   -----BEGIN CERTIFICATE-----
   <certificate_value>
   -----END CERTIFICATE-----
   ```

5. Paste the certificate into the terminal after the command prompt.
6. Press **Enter** to complete the installation.
7. Confirm the certificate is installed by running one of the following commands:

   ```
   security certificate show-user-installed
   ```

   ```
   security certificate show
   ```

   Learn more about `security certificate show` in the ONTAP command reference.

- ONTAP command reference

Set up ONTAP AutoSupport

You can configure an ONTAP cluster to deliver AutoSupport messages to NetApp technical support and send email copies to your internal support organization. As part of this, you can also test the configuration before using it in a production environment.

About this task

Beginning with ONTAP 9.5, you enable and configure AutoSupport for all nodes of a cluster simultaneously. When a new node joins the cluster, the node automatically inherits the same AutoSupport configuration. To support this, the scope of the CLI command `system node autosupport modify` is cluster-level. The `-node` command option is retained for backward compatibility, but it is ignored.

> In ONTAP 9.4 and earlier releases, the command `system node autosupport modify` is specific to each node. If your cluster is running ONTAP 9.4 or earlier, you need to enable and configure AutoSupport on each node in the cluster.

Before you begin

The recommended transport configuration for delivering AutoSupport messages to NetApp is HTTPS (HTTP with TLS). This option provides the most robust features and best security.

Review Prepare to use AutoSupport for more information before configuring your ONTAP cluster.

Steps

1. Ensure that AutoSupport is enabled:

   ```
   system node autosupport modify -state enable
   ```

2. If you want NetApp technical support to receive AutoSupport messages, use the following command:

   ```
   system node autosupport modify -support enable
   ```

   You must enable this option if you want to enable AutoSupport to work with AutoSupport OnDemand or if you want to upload large files, such as core dump and performance archive files, to technical support or a specified URL.

   > AutoSupport OnDemand is enabled by default and functional when configured to send messages to technical support using HTTPS transport protocol.

3. If you enabled NetApp technical support to receive AutoSupport messages, specify which transport protocol to use for these messages.

   You can choose from the following options:

If you want to…	Then set the following parameters of the `system node autosupport modify` command…
Use the default HTTPS protocol	a. Set `-transport` to `https`. b. If you use a proxy, set `-proxy-url` to the URL of your proxy. This configuration supports communication with AutoSupport OnDemand and uploads of large files.
Use SMTP	Set `-transport` to `smtp`. This configuration does not support AutoSupport OnDemand or uploads of large files.

4. If you want your internal support organization or a support partner to receive AutoSupport messages, perform the following actions:

   a. Identify the recipients in your organization by setting the following parameters of the `system node autosupport modify` command:

Set this parameter…	To this…
`-to`	Up to five comma-separated individual email addresses or distribution lists in your internal support organization that will receive key AutoSupport messages
`-noteto`	Up to five comma-separated individual email addresses or distribution lists in your internal support organization that will receive a shortened version of key AutoSupport messages designed for cell phones and other mobile devices
`-partner-address`	Up to five comma-separated individual email addresses or distribution lists in your support partner organization that will receive all AutoSupport messages

   b. Check that addresses are correctly configured by listing the destinations using the `system node autosupport destinations show` command.

5. If you configured the recipient addresses for your internal support organization in the previous step or you chose SMTP transport for messages to technical support, configure SMTP by setting the following parameters of the `system node autosupport modify` command:

   ◦ Set `-mail-hosts` to one or more mail hosts, separated by commas.

     You can set a maximum of five.

     You can configure a port value for each mail host by specifying a colon and port number after the mail host name: for example, `mymailhost.example.com:5678`, where 5678 is the port for the mail host.

- Set `-from` to the email address that sends the AutoSupport message.

6. Configure DNS.
7. Optionally, add command options if you want to change specific settings:

If you want to do this…	**Then set the following parameters of the `system node autosupport modify` command…**
Hide private data by removing, masking, or encoding sensitive data in the messages	Set `-remove-private-data` to `true`. If you change from `false` to `true`, all AutoSupport history and all associated files are deleted.
Stop sending performance data in periodic AutoSupport messages	Set `-perf` to `false`.

8. If you are using SMTP to deliver AutoSupport messages to NetApp, you can optionally enable TLS for improved security.
   a. Display the values available for the new parameter:

   ```
   cluster1::> system node autosupport modify -smtp-encryption ?
   ```

   b. Enable TLS for SMTP message delivery:

   ```
   cluster1::> system node autosupport modify -smtp-encryption start_tls
   ```

   c. Display the current configuration:

   ```
   cluster1::> system node autosupport show -fields smtp-encryption
   ```

9. Check the overall configuration by using the `system node autosupport show` command with the `-node` parameter.
10. Verify the AutoSupport operation by using the `system node autosupport check show` command.

    If any problems are reported, use the `system node autosupport check show-details` command to view more information.

11. Test that AutoSupport messages are being sent and received:
    a. Use the `system node autosupport invoke` command with the `-type` parameter set to `test`:

    ```
    cluster1::> system node autosupport invoke -type test -node node1
    ```

    b. Confirm that NetApp is receiving your AutoSupport messages:

```
system node autosupport history show -node local
```

The status of the latest outgoing AutoSupport message should eventually change to `sent-successful` for all appropriate protocol destinations.

c. Optionally, confirm that AutoSupport messages are being sent to your internal support organization or to your support partner by checking the email of any address that you configured for the `-to`, `-noteto`, or `-partner-address` parameters of the `system node autosupport modify` command.

Configure

Manage ONTAP AutoSupport settings

You can use System Manager to manage the settings for your AutoSupport account.

For more information about AutoSupport configuration options, including settings that are unavailable in System Manager, refer to `system-node-autosupport-modify` in the ONTAP command reference.

View AutoSupport settings

You can use System Manager to view the settings for your AutoSupport account.

Steps

1. In System Manager, click **Cluster > Settings**.

   In the **AutoSupport** section, the following information is displayed:

   - Status
   - Transport protocol
   - Proxy server
   - From email address

2. In the **AutoSupport** section, select ⋮, then select **More Options**.

   Additional information is displayed about the AutoSupport connection and email settings. Also, the transfer history of messages is listed.

Generate and send AutoSupport data

In System Manager, you can initiate the generation of AutoSupport messages and choose from which cluster node or nodes the data is collected.

Steps

1. In System Manager, select **Cluster > Settings**.

2. In the **AutoSupport** section, select ⋮, then select **Generate and Send**.
3. Enter a subject.
4. Select the check box under **Collect Data From** to specify the nodes from which to collect the data.

Test the connection to AutoSupport

From System Manager, you can send a test message to verify the connection to AutoSupport.

Steps

1. In System Manager, click **Cluster > Settings**.
2. In the **AutoSupport** section, select ⋮, then select **Test Connectivity**.
3. Enter a subject for the message.

Enable or disable AutoSupport

AutoSupport delivers proven business benefits to NetApp customers, including proactive identification of possible configuration issues and accelerated support case resolution. AutoSupport is enabled by default in new systems. If required, you can use System Manager to disable the ability of AutoSupport to monitor the health of your storage system and send you notification messages. You can enable AutoSupport again after it has been disabled.

About this task

Before you disable AutoSupport, you should be aware that you are turning off the NetApp call-home system and you'll lose the following benefits:

- **Health Monitoring**: AutoSupport monitors the health of your storage system and sends notifications to technical support and your internal support organization.
- **Automation**: AutoSupport automates the reporting of support cases. Most support cases are opened automatically before customers realize there's a problem.
- **Faster resolution**: Systems sending AutoSupport data have their support cases resolved in half of the time compared to cases for systems that not sending AutoSupport data.
- **Faster upgrades**: AutoSupport powers customer self-service workflows, such as version upgrades, add-ons, renewals, and firmware update automation in System Manager.
- **More functions**: Certain functions in other tools work only when AutoSupport is enabled, for example, some workflows in BlueXP.

Steps

1. Select **Cluster > Settings**.
2. In the **AutoSupport** section, select ⋮, then select **Disable**.
3. If you want to enable AutoSupport again, in the **AutoSupport** section, select ⋮, then select **Enable**.

Suppress the generation of support cases

Beginning with ONTAP 9.10.1, you can use System Manager to send a request to AutoSupport to suppress the generation of support cases.

About this task

To suppress the generation of support cases, you specify the nodes and number of hours for which you want the suppression to occur.

Suppressing support cases can be especially helpful if you do not want AutoSupport to create automated cases while you are performing maintenance on your systems.

Steps

1. Select **Cluster > Settings**.
2. In the **AutoSupport** section, select ⋮, then select **Suppress Support Case Generation**.
3. Enter the number of hours that you want the suppression to occur.
4. Select the nodes for which you want the suppression to occur.

Resume the generation of support cases

Beginning with ONTAP 9.10.1, you can use System Manager to resume the generation of support cases from AutoSupport if it has been suppressed.

Steps

1. Select **Cluster > Settings**.
2. In the **AutoSupport** section, select ⋮, then select **Resume Support Case Generation**.
3. Select the nodes for which you want the generation to resume.

Edit AutoSupport settings

You can use System Manager to modify the connection and email settings for your AutoSupport account.

Steps

1. Select **Cluster > Settings**.
2. In the **AutoSupport** section, select ⋮, then select **More Options**.
3. In the **Connections** section or the **Email** section, select Edit to modify the settings for either section.

Related information

- Prepare to use AutoSupport
- Set up AutoSupport

Suppress ONTAP AutoSupport case creation during scheduled maintenance windows

AutoSupport case suppression enables you to stop unnecessary cases from being created by AutoSupport messages that are triggered during scheduled maintenance windows.

Steps

1. Manually invoke an AutoSupport message with the text string `MAINT=xh`, where `x` is the duration of the maintenance window in hours. Replace <node> with the name of the node from which to send the AutoSupport message:

```
system node autosupport invoke -node <node> -message MAINT=xh
```

Related information

- ONTAP command reference
- How to suppress automatic case creation during scheduled maintenance windows

Upload files using AutoSupport

Upload ONTAP AutoSupport core dump files

When a core dump file is saved, an event message is generated. If the AutoSupport service is enabled and configured to send messages to NetApp support, an AutoSupport message is transmitted, and an automated email acknowledgement is sent to you.

Before you begin

- You have set up AutoSupport with the following settings:
  - AutoSupport is enabled on the node.
  - AutoSupport is configured to send messages to technical support.
  - AutoSupport is configured to use HTTPS transport protocol.

    The SMTP transport protocol is not supported when sending messages that include large files, such as core dump files.

About this task

You can also upload the core dump file through the AutoSupport service over HTTPS by using the `system node autosupport invoke-core-upload` command, if requested by NetApp support.

How to upload an ONTAP 9 core file for analysis

Steps

1. View the core dump files for a node by using the `system node coredump show` command.

   In the following example, core dump files are displayed for the local node:

   ```
   cluster1::> system node coredump show -node local
   Node:Type Core Name Saved Panic Time
   --------- ------------------------------------------- -----
   -----------------
   node:kernel
   core.4073000068.2013-09-11.15_05_01.nz true 9/11/2013 15:05:01
   ```

2. Generate an AutoSupport message and upload a core dump file by using the `system node autosupport invoke-core-upload` command.

   In the following example, an AutoSupport message is generated and sent to the default location, which is technical support, and the core dump file is uploaded to the default location, which is the NetApp support site:

```
cluster1::> system node autosupport invoke-core-upload -core-filename
core.4073000068.2013-09-11.15_05_01.nz -node local
```

In the following example, an AutoSupport message is generated and sent to the location specified in the URI, and the core dump file is uploaded to the URI:

```
cluster1::> system node autosupport invoke-core-upload -uri
https//files.company.com -core-filename
core.4073000068.2013-09-11.15_05_01.nz -node local
```

Upload ONTAP AutoSupport performance archive files

You can generate and send an AutoSupport message that contains a performance archive. By default, NetApp technical support receives the AutoSupport message, and the performance archive is uploaded to the NetApp support site. You can specify an alternate destination for the message and upload.

Before you begin

- You must have set up AutoSupport with the following settings:
  - AutoSupport is enabled on the node.
  - AutoSupport is configured to send messages to technical support.
  - AutoSupport is configured to use the HTTPS transport protocol.

    The SMTP transport protocol is not supported when sending messages that include large files, such as performance archive files.

About this task

You must specify a start date for the performance archive data that you want to upload. Most storage systems retain performance archives for two weeks, enabling you to specify a start date up to two weeks ago. For example, if today is January 15, you can specify a start date of January 2.

Step

1. Generate an AutoSupport message and upload the performance archive file by using the `system node autosupport invoke-performance-archive` command.

   In the following example, 4 hours of performance archive files from January 12, 2015 are added to an AutoSupport message and uploaded to the default location, which is the NetApp support site:

   ```
   cluster1::> system node autosupport invoke-performance-archive -node
   local -start-date 1/12/2015 13:42:09 -duration 4h
   ```

   In the following example, 4 hours of performance archive files from January 12, 2015 are added to an AutoSupport message and uploaded to the location specified by the URI:

```
cluster1::> system node autosupport invoke-performance-archive -node
local -start-date 1/12/2015 13:42:09 -duration 4h -uri
https://files.company.com
```

Troubleshoot

Troubleshoot ONTAP AutoSupport when messages are not received

If the system does not send the AutoSupport message, you can determine whether that is because AutoSupport cannot generate the message or cannot deliver the message.

Steps

1. Check delivery status of the messages by using the `system node autosupport history show` command.
2. Read the status.

This status	Means
initializing	The collection process is starting. If this state is temporary, all is well. However, if this state persists, there is an issue.
collection-failed	AutoSupport cannot create the AutoSupport content in the spool directory. You can view what AutoSupport is trying to collect by entering the `system node autosupport history show -detail` command.
collection-in-progress	AutoSupport is collecting AutoSupport content. You can view what AutoSupport is collecting by entering the `system node autosupport manifest show` command.
queued	AutoSupport messages are queued for delivery, but not yet delivered.
transmitting	AutoSupport is currently delivering messages.
sent-successful	AutoSupport successfully delivered the message. You can find out where AutoSupport delivered the message by entering the `system node autosupport history show -delivery` command.
ignore	AutoSupport has no destinations for the message. You can view the delivery details by entering the `system node autosupport history show -delivery` command.
re-queued	AutoSupport tried to deliver messages, but the attempt failed. As a result, AutoSupport placed the messages back in the delivery queue for another attempt. You can view the error by entering the `system node autosupport history show` command.

This status	Means
transmission-failed	AutoSupport failed to deliver the message the specified number of times and stopped trying to deliver the message. You can view the error by entering the `system node autosupport history show` command.
ondemand-ignore	The AutoSupport message was processed successfully, but the AutoSupport OnDemand service chose to ignore it.

3. Perform one of the following actions:

For this status	Do this
initializing or collection-failed	Contact NetApp Support, because AutoSupport cannot generate the message. Mention the following Knowledge Base article: AutoSupport is failing to deliver: status is stuck in initializing
ignore, re-queued, or transmission failed	Check that destinations are correctly configured for SMTP, HTTP, or HTTPS because AutoSupport cannot deliver the message.

Troubleshoot ONTAP AutoSupport message delivery over HTTPS

If the system does not send the expected AutoSupport message, and you are using HTTPS or the Automatic Update feature is not working, you can check a number of settings to resolve the problem.

Before you begin

You should have confirmed basic network connectivity and DNS lookup:

- Your node management LIF must be up for operational and administrative status.
- You must be able to ping a functioning host on the same subnet from the cluster management LIF (not a LIF on any of the nodes).
- You must be able to ping a functioning host outside the subnet from the cluster management LIF.
- You must be able to ping a functioning host outside the subnet from the cluster management LIF using the name of the host (not the IP address).

About this task

These steps are for cases when you have determined that AutoSupport can generate the message, but cannot deliver the message over HTTPS.

If you encounter errors or cannot complete a step in this procedure, determine and address the problem before proceeding to the next step.

Steps

1. Display the detailed status of the AutoSupport subsystem:

   `system node autosupport check show-details`

   This includes verifying connectivity to AutoSupport destinations by sending test messages and providing a list of possible errors in your AutoSupport configuration settings.

2. Verify the status of the node management LIF:

   ```
   network interface show -home-node local -role node-mgmt -fields
   vserver,lif,status-oper,status-admin,address,role
   ```

   The `status-oper` and `status-admin` fields should return `up`. Learn more about `up` in the ONTAP command reference.

3. Record the SVM name, the LIF name, and the LIF IP address for later use.
4. Ensure that DNS is enabled and configured correctly:

   ```
   vserver services name-service dns show
   ```

5. Address any errors returned by the AutoSupport message:

   ```
   system node autosupport history show -node * -fields node,seq-
   num,destination,last-update,status,error
   ```

   For assistance troubleshooting any returned errors, refer to the ONTAP AutoSupport (Transport HTTPS and HTTP) Resolution Guide.

6. Confirm that the cluster can access both the servers it needs and the Internet successfully:

   a. `network traceroute -lif node-management_LIF -destination DNS server`

   b. `network traceroute -lif node_management_LIF -destination support.netapp.com`

      The address `support.netapp.com` itself does not respond to ping/traceroute, but the per-hop information is valuable.

   c. `system node autosupport show -fields proxy-url`

   d. `network traceroute -node node_management_LIF -destination proxy_url`

   If any of these routes are not functioning, try the same route from a functioning host on the same subnet as the cluster, using the `traceroute` or `tracert` utility found on most third-party network clients. You can then determine whether the issue is in your network configuration or your cluster configuration. Learn more about `network traceroute` in the ONTAP command reference.

7. If you are using HTTPS for your AutoSupport transport protocol, ensure that HTTPS traffic can exit your network:

a. Configure a web client on the same subnet as the cluster management LIF.

   Ensure that all configuration parameters are the same values as for the AutoSupport configuration, including using the same proxy server, user name, password, and port.

b. Access `https://support.netapp.com` with the web client.

   The access should be successful. If not, ensure that all firewalls are configured correctly to allow HTTPS and DNS traffic, and that the proxy server is configured correctly. For more information on configuring static name resolution for support.netapp.com, see the Knowledge Base article How would a HOST entry be added in ONTAP for support.netapp.com?

8.
   Beginning with ONTAP 9.10.1, if you enable automatic updates ensure that you have HTTPS connectivity to the following additional URLs:

   - https://support-sg-naeast.netapp.com
   - https://support-sg-nawest.netapp.com

Troubleshoot ONTAP AutoSupport message delivery over SMTP

If the system cannot deliver AutoSupport messages over SMTP, you can check a number of settings to resolve the problem.

Before you begin

You should have confirmed basic network connectivity and DNS lookup:

- Your node management LIF must be up for operational and administrative status.
- You must be able to ping a functioning host on the same subnet from the cluster management LIF (not a LIF on any of the nodes).
- You must be able to ping a functioning host outside the subnet from the cluster management LIF.
- You must be able to ping a functioning host outside the subnet from the cluster management LIF using the name of the host (not the IP address).

About this task

These steps are for cases when you have determined that AutoSupport can generate the message, but cannot deliver the message over SMTP.

If you encounter errors or cannot complete a step in this procedure, determine and address the problem before proceeding to the next step.

All commands are entered at the ONTAP command-line interface, unless otherwise specified.

Steps

1. Verify the status of the node management LIF:

   `network interface show -home-node local -role node-mgmt -fields vserver,lif,status-oper,status-admin,address,role`

   The `status-oper` and `status-admin` fields should return `up`. Learn more about `up` in the ONTAP command reference.

2. Record the SVM name, the LIF name, and the LIF IP address for later use.
3. Ensure that DNS is enabled and configured correctly:

   vserver services name-service dns show

4. Display all of the servers configured to be used by AutoSupport:

   system node autosupport show -fields mail-hosts

   Record all server names displayed.

5. For each server displayed by the previous step, and `support.netapp.com`, ensure that the server or URL can be reached by the node:

   network traceroute -node local -destination *server_name*

   If any of these routes is not functioning, try the same route from a functioning host on the same subnet as the cluster, using the “traceroute” or “tracert” utility found on most third-party network clients. This assists you in determining whether the issue is in your network configuration or your cluster configuration.

6. Log in to the host designated as the mail host, and ensure that it can serve SMTP requests:

   netstat -aAn|grep 25

   `25` is the listener SMTP port number.

   A message similar to the following text is displayed:

   ```
   ff64878c tcp        0      0  *.25    *.*    LISTEN.
   ```

7. From some other host, open a Telnet session with the SMTP port of the mail host:

   telnet *mailhost* 25

   A message similar to the following text is displayed:

   ```
   220 filer.yourco.com Sendmail 4.1/SMI-4.1 ready at Thu, 30 Nov 2014
   10:49:04 PST
   ```

8. At the telnet prompt, ensure that a message can be relayed from your mail host:

   HELO *domain_name*

   MAIL FROM: *your_email_address*

   RCPT TO: autosupport@netapp.com

   `domain_name` is the domain name of your network.

   If an error is returned saying that relaying is denied, relaying is not enabled on the mail host. Contact your system administrator.

9. At the telnet prompt, send a test message:

   DATA

   SUBJECT: TESTING
   THIS IS A TEST

   .

   > Ensure that you enter the last period (.) on a line by itself. The period indicates to the mail host that the message is complete.

   If an error is returned, your mail host is not configured correctly. Contact your system administrator.

10. From the ONTAP command-line interface, send an AutoSupport test message to a trusted email address that you have access to:

    system node autosupport invoke -node local -type test

11. Find the sequence number of the attempt:

    system node autosupport history show -node local -destination smtp

    Find the sequence number for your attempt based on the timestamp. It is probably the most recent attempt.

12. Display the error for your test message attempt:

    system node autosupport history show -node local -seq-num seq_num -fields error

    If the error displayed is `Login denied`, your SMTP server is not accepting send requests from the cluster management LIF. If you do not want to change to using HTTPS as your transport protocol, contact your site network administrator to configure the SMTP gateways to address this issue.

    If this test succeeds but the same message sent to mailto:autosupport@netapp.com does not, ensure that SMTP relay is enabled on all of your SMTP mail hosts, or use HTTPS as a transport protocol.

    If even the message to the locally administered email account does not succeed, confirm that your SMTP servers are configured to forward attachments with both of these characteristics:

    - The “7z” suffix
    - The “application/x-7x-compressed” MIME type.

Troubleshoot the ONTAP AutoSupport subsystem

The `system node check show` commands can be used to verify and troubleshoot any issues related to the AutoSupport configuration and delivery.

Step

1. Use the following commands to display the status of the AutoSupport subsystem.

Use this command…	To do this…
`system node autosupport check show`	Display overall status of the AutoSupport subsystem, such as the status of AutoSupport HTTPS destination, AutoSupport SMTP destinations, AutoSupport OnDemand Server, and AutoSupport configuration
`system node autosupport check show-details`	Display detailed status of the AutoSupport subsystem, such as detailed descriptions of errors and the corrective actions

Health monitoring

Learn about ONTAP system health monitoring

Health monitors proactively monitor certain critical conditions in your cluster and raise alerts if they detect a fault or risk. If there are active alerts, the system health status reports a degraded status for the cluster. The alerts include the information that you need to respond to degraded system health.

If the status is degraded, you can view details about the problem, including the probable cause and recommended recovery actions. After you resolve the problem, the system health status automatically returns to OK.

The system health status reflects multiple separate health monitors. A degraded status in an individual health monitor causes a degraded status for the overall system health.

For details on how ONTAP supports cluster switches for system health monitoring in your cluster, you can refer to the *Hardware Universe*.

Supported switches in the Hardware Universe

For details on the causes of Cluster Switch Health Monitor (CSHM) AutoSupport messages, and the necessary actions required to resolve these alerts, you can refer to the Knowledgebase article.

AutoSupport Message: Health Monitor Process CSHM

Learn about ONTAP health monitoring components

Individual health monitors have a set of policies that trigger alerts when certain conditions occur. Understanding how health monitoring works can help you respond to problems and control future alerts.

Health monitoring consists of the following components:

- Individual health monitors for specific subsystems, each of which has its own health status

  For example, the Storage subsystem has a node connectivity health monitor.

- An overall system health monitor that consolidates the health status of the individual health monitors

  A degraded status in any single subsystem results in a degraded status for the entire system. If no subsystems have alerts, the overall system status is OK.

Each health monitor is made up of the following key elements:

- Alerts that the health monitor can potentially raise

  Each alert has a definition, which includes details such as the severity of the alert and its probable cause.

- Health policies that identify when each alert is triggered

  Each health policy has a rule expression, which is the exact condition or change that triggers the alert.

A health monitor continuously monitors and validates the resources in its subsystem for condition or state changes. When a condition or state change matches a rule expression in a health policy, the health monitor raises an alert. An alert causes the subsystem's health status and the overall system health status to become degraded.

Learn about ONTAP system health alerts response

When a system health alert occurs, you can acknowledge it, learn more about it, repair the underlying condition, and prevent it from occurring again.

When a health monitor raises an alert, you can respond in any of the following ways:

- Get information about the alert, which includes the affected resource, alert severity, probable cause, possible effect, and corrective actions.
- Get detailed information about the alert, such as the time when the alert was raised and whether anyone else has acknowledged the alert already.
- Get health-related information about the state of the affected resource or subsystem, such as a specific shelf or disk.
- Acknowledge the alert to indicate that someone is working on the problem, and identify yourself as the "Acknowledger."
- Resolve the problem by taking the corrective actions provided in the alert, such as fixing cabling to resolve a connectivity problem.
- Delete the alert, if the system did not automatically clear it.
- Suppress an alert to prevent it from affecting the health status of a subsystem.

  Suppressing is useful when you understand a problem. After you suppress an alert, it can still occur, but the subsystem health displays as "ok-with-suppressed." when the suppressed alert occurs.

Learn about ONTAP system health alert customization

You can control which alerts a health monitor generates by enabling and disabling the system health policies that define when alerts are triggered. This enables you to customize the health monitoring system for your particular environment.

You can learn the name of a policy either by displaying detailed information about a generated alert or by displaying policy definitions for a specific health monitor, node, or alert ID.

Disabling health policies is different from suppressing alerts. When you suppress an alert, it does not affect the subsystem's health status, but the alert can still occur.

If you disable a policy, the condition or state that is defined in its policy rule expression no longer triggers an alert.

Example of an alert that you want to disable

For example, suppose an alert occurs that is not useful to you. You use the `system health alert show -instance` command to obtain the Policy ID for the alert. You use the policy ID in the `system health policy definition show` command to view information about the policy. After reviewing the rule expression and other information about the policy, you decide to disable the policy. You use the `system health policy definition modify` command to disable the policy.

Learn about ONTAP AutoSupport health alert triggers

System health alerts trigger AutoSupport messages and events in the Event Management System (EMS), enabling you to monitor the health of the system using AutoSupport messages and the EMS in addition to using the health monitoring system directly.

Your system sends an AutoSupport message within five minutes of an alert. The AutoSupport message includes all alerts generated since the previous AutoSupport message, except for alerts that duplicate an alert for the same resource and probable cause within the previous week.

Some alerts do not trigger AutoSupport messages. An alert does not trigger an AutoSupport message if its health policy disables the sending of AutoSupport messages. For example, a health policy might disable AutoSupport messages by default because AutoSupport already generates a message when the problem occurs. You can configure policies to not trigger AutoSupport messages by using the `system health policy definition modify` command.

You can view a list of all of the alert-triggered AutoSupport messages sent in the previous week using the `system health autosupport trigger history show` command.

Alerts also trigger the generation of events to the EMS. An event is generated each time an alert is created and each time an alert is cleared.

Learn about available ONTAP cluster health monitors

There are several health monitors that monitor different parts of a cluster. Health monitors help you to recover from errors within ONTAP systems by detecting events, sending alerts to you, and deleting events as they clear.

Health monitor name (identifier)	Subsystem name (identifier)	Purpose
Ethernet switch	Switch (Switch-Health)	The ONTAP Ethernet Switch Health Monitor (CSHM) monitors the status of cluster and storage network switches while collecting logs for analysis. By default, CSHM polls each switch via SNMPv2c every 5 minutes to update resource tables with information on supportability, monitoring status, temperature sensors, CPU utilization, interface configurations and connections, cluster switch redundancy, and fan and power supply operations. Additionally, if configured, CSHM collects logs via SSH/SCP every hour, which are sent through AutoSupport for further analysis. Upon request, CSHM can also perform a more detailed tech-support log collection using SSH/SCP. See Switch health monitoring for further details.
MetroCluster Fabric	Switch	Monitors the MetroCluster configuration back-end fabric topology and detects misconfigurations such as incorrect cabling and zoning, and ISL failures.
MetroCluster Health	Interconnect, RAID, and storage	Monitors FC-VI adapters, FC initiator adapters, left-behind aggregates and disks, and inter-cluster ports
Node connectivity(node-connect)	CIFS nondisruptive operations (CIFS-NDO)	Monitors SMB connections for nondisruptive operations to Hyper-V applications.
	Storage (SAS-connect)	Monitors shelves, disks, and adapters at the node level for appropriate paths and connections.
System	not applicable	Aggregates information from other health monitors.

Health monitor name (identifier)	Subsystem name (identifier)	Purpose
System connectivity (system-connect)	Storage (SAS-connect)	Monitors shelves at the cluster level for appropriate paths to two HA clustered nodes.

Receive ONTAP system health alerts automatically

You can manually view system health alerts by using the `system health alert show` command. However, you should subscribe to specific Event Management System (EMS) messages to automatically receive notifications when a health monitor generates an alert.

About this task

The following procedure shows you how to set up notifications for all hm.alert.raised messages and all hm.alert.cleared messages.

All hm.alert.raised messages and all hm.alert.cleared messages include an SNMP trap. The names of the SNMP traps are `HealthMonitorAlertRaised` and `HealthMonitorAlertCleared`.

Learn more about `system health alert show` in the ONTAP command reference.

Steps

1. Use the `event destination create` command to define the destination to which you want to send the EMS messages.

```
cluster1::> event destination create -name health_alerts -mail
admin@example.com
```

   Learn more about `event destination create` in the ONTAP command reference.

2. Use the `event route add-destinations` command to route the `hm.alert.raised` message and the `hm.alert.cleared` message to a destination.

```
cluster1::> event route add-destinations -messagename hm.alert*
-destinations health_alerts
```

   Learn more about `event route add-destinations` in the ONTAP command reference.

- How to configure SNMP monitoring on DATA ONTAP

Respond to degraded ONTAP system health

When your system's health status is degraded, you can show alerts, read about the probable cause and corrective actions, show information about the degraded subsystem, and resolve the problem. Suppressed alerts are also shown so that you can modify them and see whether they have been acknowledged.

About this task

You can discover that an alert was generated by viewing an AutoSupport message or an EMS event, or by using the `system health` commands.

Steps

1. Use the `system health alert show` command to view the alerts that are compromising the system's health.
2. Read the alert's probable cause, possible effect, and corrective actions to determine whether you can resolve the problem or need more information.
3. If you need more information, use the `system health alert show -instance` command to view additional information available for the alert.
4. Use the `system health alert modify` command with the `-acknowledge` parameter to indicate that you are working on a specific alert.
5. Take corrective action to resolve the problem as described by the `Corrective Actions` field in the alert.

   The corrective actions might include rebooting the system.

   When the problem is resolved, the alert is automatically cleared. If the subsystem has no other alerts, the health of the subsystem changes to `OK`. If the health of all subsystems is OK, the overall system health status changes to `OK`.

6. Use the `system health status show` command to confirm that the system health status is `OK`.

   If the system health status is not `OK`, repeat this procedure.

Learn about responding to degraded ONTAP system health

By reviewing a specific example of degraded system health caused by a shelf that lacks two paths to a node, you can see what the CLI displays when you respond to an alert.

After starting ONTAP, you check the system health and you discover that the status is degraded:

```
cluster1::>system health status show
  Status
  ---------------
  degraded
```

You show alerts to find out where the problem is, and see that shelf 2 does not have two paths to node1:

```
      cluster1::>system health alert show
               Node: node1
           Resource: Shelf ID 2
           Severity: Major
       Indication Time: Mon Nov 10 16:48:12 2013
     Probable Cause: Disk shelf 2 does not have two paths to controller
                     node1.
    Possible Effect: Access to disk shelf 2 via controller node1 will be
                     lost with a single hardware component failure (e.g.
                     cable, HBA, or IOM failure).
 Corrective Actions: 1. Halt controller node1 and all controllers attached
to disk shelf 2.
                     2. Connect disk shelf 2 to controller node1 via two
paths following the rules in the Universal SAS and ACP Cabling Guide.
                     3. Reboot the halted controllers.
                     4. Contact support personnel if the alert persists.
```

You display details about the alert to get more information, including the alert ID:

```
      cluster1::>system health alert show -monitor node-connect -alert-id
DualPathToDiskShelf_Alert -instance
                  Node: node1
               Monitor: node-connect
              Alert ID: DualPathToDiskShelf_Alert
     Alerting Resource: 50:05:0c:c1:02:00:0f:02
             Subsystem: SAS-connect
       Indication Time: Mon Mar 21 10:26:38 2011
    Perceived Severity: Major
        Probable Cause: Connection_establishment_error
           Description: Disk shelf 2 does not have two paths to controller
node1.
    Corrective Actions: 1. Halt controller node1 and all controllers
attached to disk shelf 2.
                        2. Connect disk shelf 2 to controller node1 via
two paths following the rules in the Universal SAS and ACP Cabling Guide.
                        3. Reboot the halted controllers.
                        4. Contact support personnel if the alert
persists.
       Possible Effect: Access to disk shelf 2 via controller node1 will
be lost with a single
 hardware component failure (e.g. cable, HBA, or IOM failure).
           Acknowledge: false
              Suppress: false
                Policy: DualPathToDiskShelf_Policy
          Acknowledger: -
            Suppressor: -
Additional Information: Shelf uuid: 50:05:0c:c1:02:00:0f:02
                        Shelf id: 2
                        Shelf Name: 4d.shelf2
                        Number of Paths: 1
                        Number of Disks: 6
                        Adapter connected to IOMA:
                        Adapter connected to IOMB: 4d
Alerting Resource Name: Shelf ID 2
```

You acknowledge the alert to indicate that you are working on it.

```
      cluster1::>system health alert modify -node node1 -alert-id
DualPathToDiskShelf_Alert -acknowledge true
```

You fix the cabling between shelf 2 and node1, and then reboot the system. Then you check system health again, and see that the status is `OK`:

```
cluster1::>system health status show
  Status
  ---------------
  OK
```

Commands for monitoring the health of your ONTAP system

You can use the `system health` commands to display information about the health of system resources, to respond to alerts, and to configure future alerts. Using the CLI commands enables you to view in-depth information about how health monitoring is configured. Learn more about `system health` in the ONTAP command reference.

Display the status of system health

If you want to…	Use this command…
Display the health status of the system, which reflects the overall status of individual health monitors	`system health status show`
Display the health status of subsystems for which health monitoring is available	`system health subsystem show`

Display the status of node connectivity

If you want to…	Use this command…
Display details about connectivity from the node to the storage shelf, including port information, HBA port speed, I/O throughput, and the rate of I/O operations per second	`storage shelf show -connectivity` Use the `-instance` parameter to display detailed information about each shelf.
Display information about drives and array LUNs, including the usable space, shelf and bay numbers, and owning node name	`storage disk show` Use the `-instance` parameter to display detailed information about each drive.
Display detailed information about storage shelf ports, including port type, speed, and status	`storage port show` Use the `-instance` parameter to display detailed information about each adapter.

Monitor cluster and storage network switches

If you want to…	Use this command… (ONTAP 9.8 and later)	Use this command… (ONTAP 9.7 and earlier)
Display the switches that the cluster monitors	`system switch ethernet show`	`system cluster-switch show`
Display the switches that the cluster currently monitors, including switches that you deleted (shown in the Reason column in the command output) This command is available at the advanced privilege level	`system switch ethernet show-all`	`system cluster-switch show-all`
Configure monitoring of an undiscovered switch	`system switch ethernet create`	`system cluster-switch create`
Modify information about a switch that the cluster monitors (for example, device name, IP address, SNMP version, and community string)	`system switch ethernet modify`	`system cluster-switch modify`
Disable a switch from monitoring	`system switch ethernet modify -disable-monitoring`	`system cluster-switch modify -disable-monitoring`
Delete a switch from monitoring	`system switch ethernet delete`	`system cluster-switch delete`
Permanently remove the switch configuration information which is stored in the database (doing so reenables automatic discovery of the switch)	`system switch ethernet delete -force`	`system cluster-switch delete -force`
Perform log collection with a switch	`system switch ethernet log`	`system cluster-switch log`

See Switch health monitoring and Configure log collection for further details.

Respond to generated alerts

If you want to…	Use this command…
Display information about generated alerts, such as the resource and node where the alert was triggered, and the alert's severity and probable cause	`system health alert show`

If you want to…	Use this command…
Display information about each generated alert	`system health alert show -instance`
Indicate that someone is working on an alert	`system health alert modify`
Acknowledge an alert	`system health alert modify -acknowledge`
Suppress a subsequent alert so that it does not affect the health status of a subsystem	`system health alert modify -suppress`
Delete an alert that was not automatically cleared	`system health alert delete`
Display information about the AutoSupport messages that alerts triggered within the last week, for example, to determine whether an alert triggered an AutoSupport message	`system health autosupport trigger history show`

Configure future alerts

If you want to…	Use this command…
Enable or disable the policy that controls whether a specific resource state raises a specific alert	`system health policy definition modify`

Display information about how health monitoring is configured

If you want to…	Use this command…
Display information about health monitors, such as their nodes, names, subsystems, and status	`system health config show` Use the `-instance` parameter to display detailed information about each health monitor.
Display information about the alerts that a health monitor can potentially generate	`system health alert definition show` Use the `-instance` parameter to display detailed information about each alert definition.

If you want to…	Use this command…
Display information about health monitor policies, which determine when alerts are raised	`system health policy definition show` Use the `-instance` parameter to display detailed information about each policy. Use other parameters to filter the list of alerts—for example, by policy status (enabled or not), health monitor, alert, and so on.

Learn more about the commands described in this procedure in the ONTAP command reference.

View ONTAP environmental information

Sensors help you monitor the environmental components of your system. The information you can view about environmental sensors include their type, name, state, value, and threshold warnings.

Step

1. To display information about environmental sensors, use the `system node environment sensors show` command.

File System Analytics

Learn about ONTAP File System Analytics

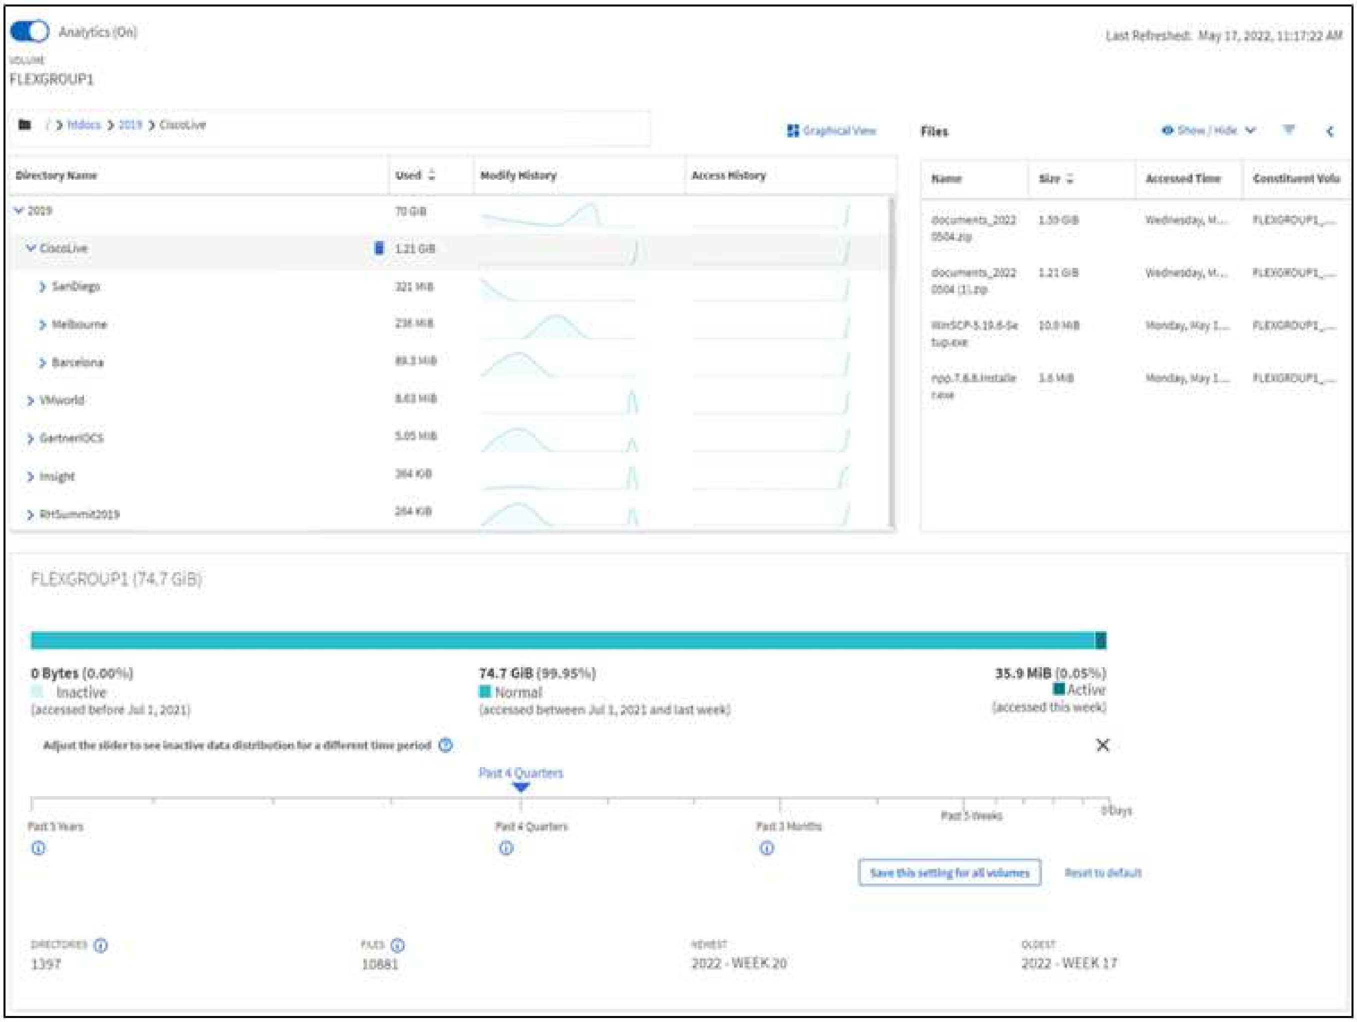
File System Analytics (FSA) was first introduced in ONTAP 9.8 to provide real-time visibility into file usage and storage capacity trends inside ONTAP FlexGroup or FlexVol volumes. This native capability eliminates the need for external tools and provides key insights into how your storage is used and whether there are opportunities to optimize the storage for your business needs.

With FSA, you have visibility at all levels of a volume's file system hierarchy in NAS. For example, you can gain usage and capacity insights at the Storage VM (SVM), volume, directory, and file levels. You can use FSA to answer questions like:

- What is filling up my storage, and are there any large files I can move to another storage location?
- Which are my most active volumes, directories, and files? Is my storage performance optimized for the needs of my users?
- How much data was added in the last month?
- Who are my most active or least active storage users?
- How much inactive or dormant data is on my primary storage? Can I move that data to a lower cost cold tier?
- Will my planned quality-of-service changes negatively impact access to critical, frequently accessed files?

File System Analytics is integrated into ONTAP System Manager. Views within System Manager provide:

* Real-time visibility for effective data management and operation
* Real-time data collection and aggregation
* Subdirectory and file sizes and counts, together with associated performance profiles
* File age histograms for modify and access histories



Supported volume types

File System Analytics is designed to provide visibility on volumes with active NAS data, with the exception of FlexCache caches and SnapMirror destination volumes.

File System Analytics feature availability

Each ONTAP release expands the scope of File System Analytics.

	ONTAP 9.14.1 and later	ONTAP 9.13.1	ONTAP 9.12.1	ONTAP 9.11.1	ONTAP 9.10.1	ONTAP 9.9.1	ONTAP 9.8
Visualization in System Manager	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Capacity analytics	Yes	Yes	Yes	Yes	Yes	Yes	Yes

	ONTAP 9.14.1 and later	ONTAP 9.13.1	ONTAP 9.12.1	ONTAP 9.11.1	ONTAP 9.10.1	ONTAP 9.9.1	ONTAP 9.8
Inactive data information	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Support for volumes transitioned from Data ONTAP 7-Mode	Yes	Yes	Yes	Yes	Yes	Yes	No
Ability to customize inactive period in System Manager	Yes	Yes	Yes	Yes	Yes	Yes	No
Volume-level Activity Tracking	Yes	Yes	Yes	Yes	Yes	No	No
Download Activity Tracking data to CSV	Yes	Yes	Yes	Yes	Yes	No	No
SVM-level Activity Tracking	Yes	Yes	Yes	Yes	No	No	No
Timeline	Yes	Yes	Yes	Yes	No	No	No
Usage Analytics	Yes	Yes	Yes	No	No	No	No
Option to enable File System Analytics by default	Yes	Yes	No	No	No	No	No

Related information

- TR 4687: Best-practice guidelines for ONTAP File System Analytics

- Knowledge Base: High or fluctuating latency after turning on NetApp ONTAP File System Analytics

Enable ONTAP File System Analytics

To collect and display usage data such as capacity analytics, you need to enable File System Analytics on a volume.

> Beginning with ONTAP 9.17.1, volumes created on newly created SVMs on ONTAP clusters allocated for NAS protocols now have File System Analytics (FSA) enabled by default. FSA is automatically activated as soon as a volume is created, providing immediate analytics capabilities without additional configuration. If you do not want to enable File System Analytics on new volumes, you must disable FSA on new volumes from the SVM.

About this task

- Beginning with ONTAP 9.8, you can enable File System Analytics on a new or existing volume. If you upgrade a system to ONTAP 9.8 or later, ensure that all upgrade processes have completed before you enable File System Analytics.
- The amount of time it takes to enable analytics depends on the size and contents of the volume. System Manager displays progress and presents analytics data when complete. If you need more precise information about the initialization scan progress, you can use the ONTAP CLI command `volume analytics show`.
    - Beginning with ONTAP 9.15.1, you can conduct only four initialization scans concurrently on a node. You must wait for a scan to complete before initiating a new scan. ONTAP also enforces that there is enough available space available on the volume and presents an error message if there is not. Ensure that at least 5 to 8 percent of the volume's available space is free. If the volume has autosize enabled, calculate the available size based on the maximum autogrow size.
    - Beginning with ONTAP 9.14.1, ONTAP provides progress tracking for the initialization scan in addition to notifications about throttling events that affect the scan progress.
    - For further considerations related to the initialization scan, see Scan considerations.
    - Learn more about `volume analytics show` in the ONTAP command reference.

Enable File System Analytics on an existing volume

You can enable File System Analytics with ONTAP System Manager or the CLI.

Example 38. Step

System Manager

ONTAP 9.10.1 and later	ONTAP 9.9.1 and ONTAP 9.8
1. Select **Storage > Volumes**. 2. Select the desired volume. From the individual volume menu, select **File System > Explorer**. 3. Select **Enable Analytics** or **Disable Analytics**.	1. Select **Storage > Volumes**. 2. Select the desired volume, then select **Explorer**. 3. Select **Enable Analytics** or **Disable Analytics**.

CLI

Enable File System Analytics with the CLI

1. Run the following command:

```
volume analytics on -vserver <svm_name> -volume <volume_name> [-
foreground {true|false}]
```

   By default, the command runs in the foreground; ONTAP displays progress and presents analytics data when complete. If you need more precise information, you can run the command in the background by using the `-foreground false` option and then use the `volume analytics show` command to display initialization progress in the CLI.

2. After successfully enabling File System Analytics, use System Manager or the ONTAP REST API to display the analytic data.

Learn more about `volume analytics on` in the ONTAP command reference.

Modify default File System Analytics settings

Beginning with ONTAP 9.13.1, you can modify SVM or clusters settings to enable File System Analytics by default on new volumes.

Example 39. Steps

System Manager

If you are using System Manager, you can modify the storage VM or cluster settings to enable capacity analytics and Activity Tracking at volume creation by default. Default enablement only applies to volumes created after you modify the settings, not existing volumes.

Modify File System Analytics settings on a cluster

1. In System Manager, navigate to **Cluster settings**.
2. In **Cluster settings**, review the File System Settings tab. To modify the settings, select the ⚙ icon.
3. In the **Activity Tracking** field, enter the names of the SVMs to enable Activity Tracking for by default. Leaving the field blank will leave Activity Tracking disabled on all SVMs.

   Uncheck the **Enable on new storage VMs** box to disable Activity Tracking by default on new storage VMs.

4. In the **Analytics** field, enter the names of the storage VMs you want capacity analytics enabled for by default. Leaving the field blank will leave capacity analytics disabled on all SVMs.

   Uncheck the **Enable on new storage VMs** box to disable capacity analytics by default on new storage VMs.

5. Select **Save**.

Modify File System Analytics settings on an SVM

1. Select the SVM you want to modify then **Storage VM settings**.
2. In the **File System Analytics** card, use the toggles to enable or disable Activity Tracking and capacity analytics for all new volumes on the storage VM.

CLI

You can configure the storage VM to enable File System Analytics by default on new volumes using the ONTAP CLI.

Enable File System Analytics by default on an SVM

1. Modify the SVM to enable capacity analytics and Activity Tracking by default on all newly created volumes:

   ```
   vserver modify -vserver <svm_name> -auto-enable-activity-tracking
   true -auto-enable-analytics true
   ```

   Learn more about `vserver modify` in the ONTAP command reference.

Related information

- ONTAP command reference

View ONTAP file system activity with FSA

After File System Analytics (FSA) is enabled, you can view the root directory contents of a selected volume sorted by the space used in each subtree.

Select any file system object to browse the file system and to display detailed information about each object in a directory. Information about directories can also be displayed graphically. Over time, historical data is displayed for each subtree. Space used is not sorted if there are more than 3000 directories.

Explorer

The File System Analytics **Explorer** screen consists of three areas:

- Tree view of directories and subdirectories; expandable list showing name, size, modify history, and access history.
- Files; showing name, size, and accessed time for the object selected in the directory list.
- Active and inactive data comparison for the object selected in the directory list.

  Beginning with ONTAP 9.9.1, you can customize the range to be reported. The default value is one year. Based on these customizations, you can take corrective actions, such as moving volumes and modifying the tiering policy.

Accessed time is shown by default. However, if the volume default has been altered from the CLI (by setting the `-atime-update` option to `false` with the `volume modify` command), then only last modified time is shown. For example:

- The tree view will not display the **access history**.
- The files view will be altered.
- The active/inactive data view will be based on modified time (`mtime`).

Using these displays, you can examine the following:

- File system locations consuming the most space
- Detailed information about a directory tree, including file and subdirectory count within directories and subdirectories
- File system locations that contain old data (for example, scratch, temp, or log trees)

Keep the following points in mind when interpreting FSA output:

- FSA show where and when your data is in use, not how much data is being processed. For example, large space consumption by recently accessed or modified files does not necessarily indicate high system processing loads.
- The way that the **Volume Explorer** tab calculates space consumption for FSA might differ from other tools. In particular, there could be significant differences compared to the consumption reported in the **Volume Overview** if the volume has storage efficiency features enabled. This is because the **Volume Explorer** tab does not include efficiency savings.
- Due to space limitations in the directory display, it is not possible to view a directory depth greater than 8 levels in the *List View*. To view directories more than 8 levels deep, you must switch to *Graphical View*, locate the desired directory, then switch back to *List View*. This will allow additional screen space in the display.

Steps

1. View the root directory contents of a selected volume:

Beginning with ONTAP 9.10.1	In ONTAP 9.9.1 and 9.8
Select **Storage > Volumes**, select the desired volume. From the individual volume menu, select **File System > Explorer**.	Click **Storage > Volumes**, select the desired volume, then click **Explorer**.

Related information

- volume modify

Enable ONTAP Activity Tracking with FSA

Beginning with ONTAP 9.10.1, File System Analytics includes an Activity Tracking feature that allows you to identify hot objects and download the data as a CSV file. Beginning with ONTAP 9.11.1, Activity Tracking is expanded to the SVM scope. Also beginning with ONTAP 9.11.1, System Manager features a timeline for Activity Tracking, allowing you to look through up to five minutes of Activity Tracking data.

Activity Tracking enables monitoring in four categories:

- Directories
- Files
- Clients
- Users

For each category monitored, Activity Tracking will display read IOPs, write IOPs, read throughputs, and write throughputs. Queries on Activity Tracking refresh every 10 to 15 seconds pertaining to hot spots seen in the system over the previous five-second interval.

Activity tracking information is approximate, and the accuracy of the data depends on the distribution of the incoming I/O traffic.

When viewing Activity Tracking in System Manager at the volume level, only the menu of the expanded volume will actively refresh. If the view of any volumes are collapsed, they will not refresh until the volume display is expanded. You can stop the refreshes with the **Pause Refresh** button. Activity data can be downloaded in a CSV format that will display all the point-in-time data captured for the selected volume.

With the timeline feature available beginning with ONTAP 9.11.1, you can keep a record of hotspot activity on a volume or SVM, continuously updating approximately every five seconds and retaining the previous five minutes of data. Timeline data is only retained for fields that are visible area of the page. If you collapse a tracking category or scroll so the timeline is out of view, the timeline will stop collecting data. By default, timelines are disabled and will automatically be disabled when you navigate away from the Activity tab.

Enable Activity Tracking for a single volume

You can enable Activity Tracking with ONTAP System Manager or the CLI.

About this task

If you use RBAC with the ONTAP REST API or System Manager, you will need to create custom roles to manage access to Activity Tracking. See Role-based access control for this process.

System Manager

Steps

1. Select **Storage > Volumes**. Select the desired volume. From the individual volume menu, select File System and then select the Activity tab.
2. Ensure **Activity Tracking** is turned on to view individual reports on top directories, files, clients, and users.
3. To analyze data in greater depth without refreshes, select **Pause Refresh**. You can download the data to have a CSV record of the report as well.

CLI

Steps

1. Enable Activity Tracking:

   ```
   volume activity-tracking on -vserver svm_name -volume volume_name
   ```

2. Check if the Activity Tracking state for a volume is on or off with the command:

   ```
   volume activity-tracking show -vserver svm_name -volume volume_name -state
   ```

3. Once enabled, use ONTAP System Manager or the ONTAP REST API to display Activity Tracking data.

Enable Activity Tracking for multiple volumes

You can enable Activity Tracking for multiple volumes with System Manager or the CLI.

About this task

If you use RBAC with the ONTAP REST API or System Manager, you will need to create custom roles to manage access to Activity Tracking. See Role-based access control for this process.

System Manager

Enable for specific volumes

1. Select **Storage > Volumes**. Select the desired volume. From the individual volume menu, select File System and then select the Activity tab.
2. Select the volumes that you want to enable Activity Tracking on. At the top of the volume list, select the **More Options** button. Select **Enable Activity Tracking**.
3. To view Activity Tracking at the SVM level, select the specific SVM you would like to view from **Storage > Volumes**. Navigate to the File System tab then Activity and you will see data for the volumes that have Activity Tracking enabled.

Enable for all volumes

1. Select **Storage > Volumes**. Select an SVM from the menu.
2. Navigate to the **File System** tab, choose the **More** tab to enable Activity Tracking on all volumes in the SVM.

CLI

Beginning with ONTAP 9.13.1, you can enable Activity Tracking for multiple volumes using the ONTAP CLI.

Steps

1. Enable Activity Tracking:

   ```
   volume activity-tracking on -vserver svm_name -volume [*|!volume_names]
   ```

   Use `*` to enable Activity Tracking for all volumes on the specified storage VM.

   Use `!` followed by volume names to enable Activity Tracking for all volumes on the SVM except the named volumes.

2. Confirm the operation succeeded:

   ```
   volume show -fields activity-tracking-state
   ```

3. Once enabled, use ONTAP System Manager or the ONTAP REST API to display Activity Tracking data.

Enable ONTAP usage analytics with FSA

Beginning with ONTAP 9.12.1, you can enable usage analytics to see which directories within a volume are using the most space. You can view the total number of directories in a volume or the total number of files in a volume. Reporting is limited to the 25 directories that use the most space.

Analytics for large directories refresh every 15 minutes. You can monitor the most recent refresh by checking the Last Refreshed timestamp at the top of the page. You can also click the Download button to download data to an Excel workbook. The download operation runs in the background and presents the most recently reported information for the selected volume. If the scan returns without any results, ensure the volume is online. Events such as SnapRestore will cause File System Analytics to rebuild its list of large directories.

Steps

1. Select **Storage > Volumes**. Select the desired volume.
2. From the individual volume menu, select **File System**. Then select the **Usage** tab.
3. Toggle the **Analytics** switch to enable usage analytics.
4. System Manager will display a bar graph identifying the directories with the largest size in descending order.

> ONTAP might display partial data or no data at all while the list of top directories is being collected. The progress of the scan can be in the **Usage** tab that displays during the scan.

To gain more insights into a specific directory, you can view ONTAP file system activity.

Take corrective action based on ONTAP analytics in FSA

Beginning with ONTAP 9.9.1, you can take corrective actions based on current data and desired outcomes directly from the File System Analytics displays.

Delete directories and files

In the Explorer display, you can select directories or individual files to delete. Directories are deleted with low-latency asynchronous directory delete functionality. (Asynchronous directory delete is also available beginning with ONTAP 9.9.1 without analytics enabled.)

Table 5. Steps

Beginning with ONTAP 9.10.1	In ONTAP 9.9.1
1. Select **Storage > Volumes** and select the desired volume name. 2. In the individual volume page, select the **File system** tab, and then select the **Explorer** tab. 3. In the **Explorer** view, select the desired directory. 4. To delete, hover over a file or folder, and the delete option appears. You can only delete one object at a time. When directories and files are deleted, the new storage capacity values are not displayed immediately.	1. Select **Storage > Volumes**. 2. Select the desired volume, then select **Explorer**. 3. In the **Explorer** view, select the desired directory. 4. To delete, hover over a file or folder, and the delete option appears.

Assign media cost in storage tiers to compare costs of inactive data storage locations

Media cost is a value that you assign based on your evaluation of storage costs, represented as your choice of currency per GB. When set, System Manager uses the assigned media cost to project estimated savings when you move volumes.

The media cost you set is not persistent; it can only be set for a single browser session.

Steps

1. Click **Storage > Tiers**, then click **Set Media Cost** in the desired local tier (aggregate) tiles.

   Be sure to select active and inactive tiers to enable comparison.

2. Enter a currency type and amount.

   When you enter or change the media cost, the change is made in all media types.

Move volumes to reduce storage costs

Based on analytics displays and media cost comparisons, you can move volumes to less expensive storage in local tiers.

Only one volume at a time can be compared and moved.

Steps

1. After enabling media cost display, click **Storage > Tiers**, then click **Volumes**.
2. To compare destination options for a volume, click ⋮ for the volume, then click **Move**.
3. In the **Select Destination Local Tier** display, select destination tiers to display the estimated cost difference.
4. After comparing options, select the desired tier and click **Move**.

Role-based access control with ONTAP File System Analytics

Beginning with ONTAP 9.12.1, ONTAP includes a predefined role-based access control (RBAC) role called `admin-no-fsa`. The `admin-no-fsa` role grants administrator-level privileges but prevents the user from performing operations related to the `files` endpoint (i.e. File System Analytics) in the ONTAP CLI, REST API, and in System Manager.

For more information on the `admin-no-fsa` role, refer to Predefined roles for cluster administrators.

If you are using a version of ONTAP released prior to ONTAP 9.12.1, you will need to create a dedicated role to control access to File System Analytics. In versions of ONTAP prior to ONTAP 9.12.1, you must configure RBAC permissions through the ONTAP CLI or ONTAP REST API.

System Manager

Beginning with ONTAP 9.12.1, you can configure RBAC permissions for File System Analytics using System Manager.

Steps

1. Select **Cluster > Settings**. Under **Security**, navigate to **Users and Roles** and select →.
2. Under **Roles**, select + Add.
3. Provide a name for the role. Under Role Attributes, configure the access or restrictions for the user role by providing the appropriate API endpoints. See the table below for primary paths and secondary paths to configure File System Analytics access or restrictions.

Restriction	Primary Path	Secondary Path
Activity Tracking on volumes	`/api/storage/volumes`	• `/:uuid/top-metrics/directories` • `/:uuid/top-metrics/files` • `/:uuid/top-metrics/clients` • `/:uuid/top-metrics/users`
Activity Tracking on SVMs	`/api/svm/svms`	• `/:uuid/top-metrics/directories` • `/:uuid/top-metrics/files` • `/:uuid/top-metrics/clients` • `/:uuid/top-metrics/users`
All File System Analytics operations	`/api/storage/volumes`	`/:uuid/files`

You can use `/*/` instead of an UUID to set the policy for all volumes or SVMs at the endpoint.

Choose the access privileges for each endpoint.

4. Select **Save**.
5. To assign the role to a user or users, see Control administrator access.

CLI

If you are using a version of ONTAP released prior to ONTAP 9.12.1, use the ONTAP CLI to create a custom-role.

Steps

1. Create a default role to have access to all features.

   This needs to be done before creating the restrictive role to ensure the role is only restrictive on the Activity Tracking:

   ```
   security login role create -cmddirname DEFAULT -access all -role
   storageAdmin
   ```

2. Create the restrictive role:

   ```
   security login role create -cmddirname "volume file show-disk-usage"
   -access none -role storageAdmin
   ```

3. Authorize roles to access the SVM's web services:

   - `rest` for REST API calls
   - `security` for password protection
   - `sysmgr` for System Manager access

     ```
     vserver services web access create -vserver svm-name -name_ -name rest
     -role storageAdmin
     ```

     ```
     vserver services web access create -vserver svm-name -name security
     -role storageAdmin
     ```

     ```
     vserver services web access create -vserver svm-name -name sysmgr -role
     storageAdmin
     ```

4. Create a user.

   You must issue a distinct create command for each application you would like to apply to the user. Calling create multiple times on the same user simply applies all the applications to that one user and does not create a new user each time. The `http` parameter for application type applies for the ONTAP REST API and System Manager.

   ```
   security login create -user-or-group-name storageUser -authentication
   -method password -application http -role storageAdmin
   ```

5. With the new user credentials, you can now log in to System Manager or use the ONTAP REST API to access File Systems Analytics data.

More information

- Predefined roles for cluster administrators
- Control administrator access with System Manager
- Learn more about RBAC roles and the ONTAP REST API
- security login create

Considerations for ONTAP File System Analytics

You should be aware of certain usage limits and potential performance impacts associated with implementing File System Analytics.

SVM-protected relationships

If you have enabled File System Analytics on volumes whose containing SVM is in a protection relationship, the analytics data is not replicated to the destination SVM. If the source SVM must be resynchronized in a recovery operation, you must manually reenable analytics on desired volumes after recovery.

Performance considerations

In some cases, enabling File System Analytics could negatively impact performance during the initial metadata collection. This is most typically seen on systems that are at maximum utilization. To avoid enabling analytics on such systems, you can use ONTAP System Manager performance monitoring tools.

If you experience a notable increase in latency, refer to the Knowledge Base article High or fluctuating latency after turning on NetApp ONTAP File System Analytics.

Scan considerations

When you enable capacity analytics, ONTAP conducts an initialization scan for capacity analytics. The scan accesses metadata for all files in volumes for which capacity analytics is enabled. No file data is read during the scan. Beginning with ONTAP 9.14.1, you can track the progress of the scan with the REST API, in the **Explorer** tab of System Manager, or with the `volume analytics show` CLI command. If there is a throttling event, ONTAP provides a notification.

When enabling File System Analytics on a volume, ensure that at least 5 to 8 percent of the volume's available space is free. If the volume has autosize enabled, calculate the available size based on the maximum autogrow size. Beginning with ONTAP 9.15.1, ONTAP presents an error message if there's not enough space available when you enable File System Analytics on a volume.

After the scan completes, File System Analytics is continuously updated in real time as the file system changes.

The time required for the scan is proportional to the number of directories and files on the volume. Because the scan collects metadata, file size does not impact the scan time.

For more information about the initialization scan, see TR-4867: Best practice guidelines for File System Analytics.

Best practices

You should start the scan on volumes that do not share aggregates. You can see which aggregates are currently hosting which volumes using the command:

```
volume show -volume comma-separated-list_of_volumes -fields aggr-list
```

While the scan runs, volumes continue to serve client traffic. It's recommended you start the scan during periods where you anticipate lower client traffic.

If client traffic increases, it will consume system resources and cause the scan to take longer.

Beginning with ONTAP 9.12.1, you can pause data collection in System Manager and with the ONTAP CLI.

- If you are using the ONTAP CLI:

◦ You can pause data collection with the command: `volume analytics initialization pause -vserver svm_name -volume volume_name`

◦ Once client traffic has slowed, you can resume data collection with the command: `volume analytics initialization resume -vserver svm_name -volume volume_name`

- If you are using System Manager, in the **Explorer** view of the volume menu, you use the **Pause Data Collection** and **Resume Data Collection** buttons to manage the scan.

EMS configuration

Learn about ONTAP EMS configuration

You can configure ONTAP 9 to send important EMS (Event Management System) event notifications directly to an email address, syslog server, Simple Management Network Protocol (SNMP) traphost, or webhook application so that you are immediately notified of system issues that require prompt attention.

Because important event notifications are not enabled by default, you need to configure the EMS to send notifications to either an email address, a syslog server, an SNMP traphost, or webhook application.

Review release-specific versions of the ONTAP 9 EMS Reference.

If your EMS event mapping uses deprecated ONTAP command sets (such as event destination, event route), it's recommended that you update your mapping. Learn how to update your EMS mapping from deprecated ONTAP commands.

Configure ONTAP EMS event notifications and filters with System Manager

You can use System Manager to configure how the Event Management System (EMS) delivers event notifications so that you can be notified of system issues that require your prompt attention.

ONTAP version	With System Manager, you can…
ONTAP 9.12.1 and later	Specify Transport Layer Security (TLS) protocol when sending events to remote syslog servers.
ONTAP 9.10.1 and later	Configure email addresses, syslog servers, and webhook applications, as well as SNMP traphosts.
ONTAP 9.7 to 9.10.0	Configure only SNMP traphosts. You can configure other EMS destination with the ONTAP CLI. See EMS configuration overview.

Add an EMS event notification destination

You can use System Manager to specify to where you want EMS messages sent.

Beginning with ONTAP 9.12.1, EMS events can be sent to a designated port on a remote syslog server via the Transport Layer Security (TLS) protocol. Learn more about `event notification destination create` in the ONTAP command reference.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click ⋮, then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Events Destinations** tab.
4. Click + Add .
5. Specify a name, an EMS destination type, and filters.

   ⓘ If needed, you can add a new filter. Click **Add a New Event Filter**.

6. Depending on the EMS destination type you selected, specify the following:

To configure…	Specify or select…
SNMP traphost	• Traphost name
Email (Beginning with 9.10.1)	• Destination email address • Mail server • From email address
Syslog server (Beginning with 9.10.1)	• Host name or IP address of the server • Syslog port (beginning with 9.12.1) • Syslog transport (beginning with 9.12.1) Selecting **TCP Encrypted** enables the Transport Layer Security (TLS) protocol. If no value is entered for **Syslog port**, a default is used based on the **Syslog transport** selection.
Webhook (Beginning with 9.10.1)	• Webhook URL • Client authentication (select this option to specify a client certificate)

Create a new EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to define new customized filters that specify the rules for handling EMS notifications.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click ⋮, then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Click + Add .
5. Specify a name, and select whether you want to copy rules from an existing event filter or add new rules.
6. Depending on your choice, perform the following steps:

If you choose….	Then, perform these steps…
Copy rules from existing event filter	1. Select an existing event filter. 2. Modify the existing rules. 3. Add other rules, if needed, by clicking + Add .
Add new rules	Specify the type, name pattern, severities, and SNMP trap type for each new rule.

Edit an EMS event notification destination

Beginning with ONTAP 9.10.1, you can use System Manager to change the event notification destination information.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click ⋮, then click **View Event Destinations**.
3. On the **Notifications Management** page, select the **Events Destinations** tab.
4. Next to the name of the event destination, click ⋮, then click **Edit**.
5. Modify the event destination information, then click **Save**.

Edit an EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to modify customized filters to change how event notifications are handled.

> You cannot modify system-defined filters.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click ⋮, then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Next to the name of the event filter, click ⋮, then click **Edit**.
5. Modify the event filter information, then click **Save**.

Delete an EMS event notification destination

Beginning with ONTAP 9.10.1, you can use System Manager to delete an EMS event notification destination.

> You cannot delete SNMP destinations.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click ⋮, then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Events Destinations** tab.

4. Next to the name of the event destination, click ⋮, then click **Delete**.

Delete an EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to delete customized filters.

> You cannot delete system-defined filters.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click ⋮, then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Next to the name of the event filter, click ⋮, then click **Delete**.

Configure EMS event notifications with the CLI

ONTAP EMS configuration workflow

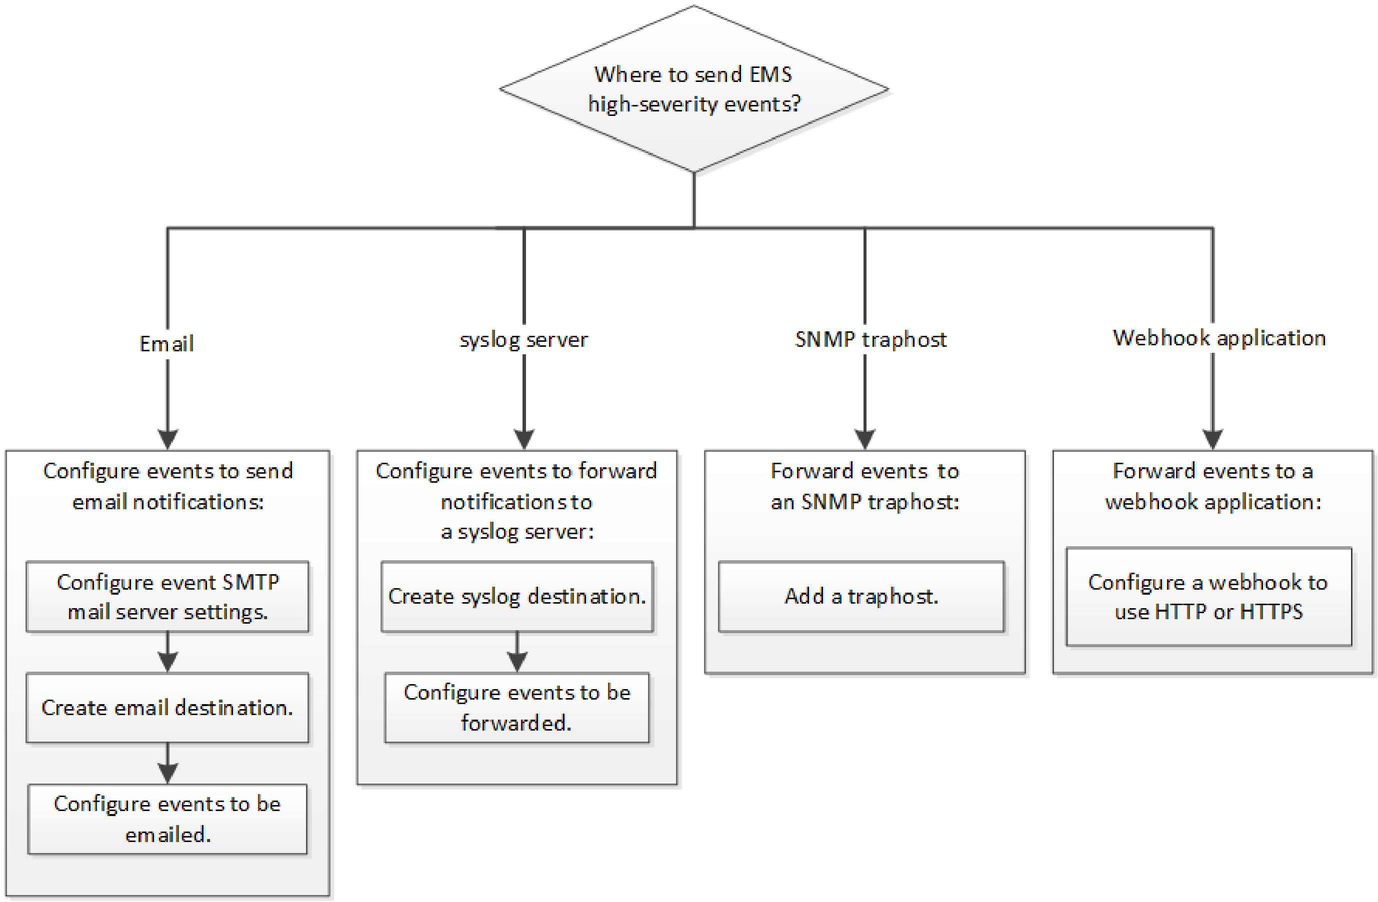
You must configure important EMS event notifications to be sent either as email, forwarded to a syslog server, forwarded to an SNMP traphost, or forwarded to a webhook application. This helps you to avoid system disruptions by taking corrective actions in a timely manner.

About this task

If your environment already contains a syslog server for aggregating the logged events from other systems, such as servers and applications, then it is easier to use that syslog server also for important event notifications from storage systems.

If your environment does not already contain a syslog server, then it is easier to use email for important event notifications.

If you already forward event notifications to an SNMP traphost, then you might want to monitor that traphost for important events.



Choices

- Set EMS to send event notifications.

If you want…	Refer to this…
The EMS to send important event notifications to an email address	Configure important EMS events to send email notifications
The EMS to forward important event notifications to a syslog server	Configure important EMS events to forward notifications to a syslog server
If you want the EMS to forward event notifications to an SNMP traphost	Configure SNMP traphosts to receive event notifications
If you want the EMS to forward event notifications to a webhook application	Configure important EMS events to forward notifications to a webhook application

Configure important ONTAP EMS events to send email notifications

To receive email notifications of the most important events, you must configure the EMS to send email messages for events that signal important activity.

Before you begin

DNS must be configured on the cluster to resolve the email addresses.

About this task

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

Steps

1. Configure the event SMTP mail server settings:

   ```
   event config modify -mail-server mailhost.your_domain -mail-from
   cluster_admin@your_domain
   ```

   Learn more about `event config modify` in the ONTAP command reference.

2. Create an email destination for event notifications:

   ```
   event notification destination create -name storage-admins -email
   your_email@your_domain
   ```

   Learn more about `event notification destination create` in the ONTAP command reference.

3. Configure the important events to send email notifications:

   ```
   event notification create -filter-name important-events -destinations storage-
   admins
   ```

   Learn more about `event notification create` in the ONTAP command reference.

Configure important ONTAP EMS events to forward notifications to a syslog server

To log notifications of the most severe events on a syslog server, you must configure the EMS to forward notifications for events that signal important activity.

Before you begin

DNS must be configured on the cluster to resolve the syslog server name.

About this task

If your environment does not already contain a syslog server for event notifications, you must first create one. If your environment already contains a syslog server for logging events from other systems, then you might want to use that one for important event notifications.

You can perform this task any time the cluster is running by entering the commands on the ONTAP CLI.

Beginning with ONTAP 9.12.1, EMS events can be sent to a designated port on a remote syslog server via the Transport Layer Security (TLS) protocol. Two new parameters are available:

`tcp-encrypted`

When `tcp-encrypted` is specified for the `syslog-transport`, ONTAP verifies the identity of the destination host by validating its certificate. The default value is `udp-unencrypted`.

`syslog-port`

The default value `syslog-port` parameter depends on the setting for the `syslog-transport` parameter. If `syslog-transport` is set to `tcp-encrypted`, `syslog-port` has the default value 6514.

Steps

1. Create a syslog server destination for important events:

   ```
   event notification destination create -name syslog-ems -syslog syslog-server-
   address -syslog-transport {udp-unencrypted|tcp-unencrypted|tcp-encrypted}
   ```

   Beginning with ONTAP 9.12.1, the following values can be specified for `syslog-transport`:

   - `udp-unencrypted` - User Datagram Protocol with no security
   - `tcp-unencrypted` - Transmission Control Protocol with no security
   - `tcp-encrypted` - Transmission Control Protocol with Transport Layer Security (TLS)

     The default protocol is `udp-unencrypted`.

   Learn more about `event notification destination create` in the ONTAP command reference.

2. Configure the important events to forward notifications to the syslog server:

   ```
   event notification create -filter-name important-events -destinations syslog-
   ems
   ```

   Learn more about `event notification create` in the ONTAP command reference.

Configure ONTAP SNMP traphosts to receive event notifications

To receive event notifications on an SNMP traphost, you must configure a traphost.

Before you begin

- SNMP and SNMP traps must be enabled on the cluster.

  > SNMP and SNMP traps are enabled by default.

- DNS must be configured on the cluster to resolve the traphost names.

About this task

If you do not already have an SNMP traphost configured to receive event notifications (SNMP traps), you must add one.

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

Step

1. If your environment does not already have an SNMP traphost configured to receive event notifications, add one:

   ```
   system snmp traphost add -peer-address snmp_traphost_name
   ```

   All event notifications that are supported by SNMP by default are forwarded to the SNMP traphost.

Configure important ONTAP EMS events to forward notifications to a webhook application

You can configure ONTAP to forward important event notifications to a webhook application. The configuration steps needed depend on the level of security you choose.

Prepare to configure EMS event forwarding

There are several concepts and requirements you should consider before configuring ONTAP to forward event notifications to a webhook application.

Webhook application

You need a webhook application capable of receiving the ONTAP event notifications. A webhook is a user-defined callback routine that extends the capability of the remote application or server where it runs. Webhooks are called or activated by the client (in this case ONTAP) by sending an HTTP request to the destination URL. Specifically, ONTAP sends an HTTP POST request to the server hosting the webhook application along with the event notification details formatted in XML.

Security options

There are several security options available depending on how the Transport Layer Security (TLS) protocol is used. The option you choose determines the required ONTAP configuration.

> TLS is a cryptographic protocol that is widely used on the internet. It provides privacy as well as data integrity and authentication using one or more public key certificates. The certificates are issued by trusted certificate authorities.

HTTP

You can use HTTP to transport the event notifications. With this configuration, the connection is not secure. The identities of the ONTAP client and webhook application are not verified. Further, the network traffic is not encrypted or protected. See Configure a webhook destination to use HTTP for the configuration details.

HTTPS

For additional security, you can install a certificate at the server hosting the webhook routine. The HTTPS protocol is used by ONTAP to verify the identity of the webhook application server as well as by both parties to ensure the privacy and integrity of the network traffic. See Configure a webhook destination to use HTTPS for the configuration details.

HTTPS with mutual authentication

You can further enhance the HTTPS security by installing a client certificate at the ONTAP system issuing the webbook requests. In addition to ONTAP verifying the identity of the webhook application server and protecting the network traffic, the webhook application verifies the identity of the ONTAP client. This two-way peer authentication is known as *Mutual TLS*. See Configure a webhook destination to use HTTPS with mutual authentication for the configuration details.

Related information

- The Transport Layer Security (TLS) Protocol Version 1.3

Configure a webhook destination to use HTTP

You can configure ONTAP to forward event notifications to a webhook application using HTTP. This is the least secure option but the simplest to set up.

Steps

1. Create a new destination `restapi-ems` to receive the events:

   ```
   event notification destination create -name restapi-ems -rest-api-url
   http://<webhook-application>
   ```

   In the above command, you must use the **HTTP** scheme for the destination.

   Learn more about `event notification destination create` in the ONTAP command reference.

2. Create a notification linking the `important-events` filter with the `restapi-ems` destination:

   ```
   event notification create -filter-name important-events -destinations restapi-
   ems
   ```

   Learn more about `event notification create` in the ONTAP command reference.

Configure a webhook destination to use HTTPS

You can configure ONTAP to forward event notifications to a webhook application using HTTPS. ONTAP uses the server certificate to confirm the identity of the webhook application as well as secure the network traffic.

Before you begin

- Generate a private key and certificate for the webhook application server
- Have the root certificate available to install in ONTAP

Steps

1. Install the appropriate server private key and certificates at the server hosting your webhook application. The specific configuration steps are dependent on the server.
2. Install the server root certificate in ONTAP:

   ```
   security certificate install -type server-ca
   ```

   The command will ask for the certificate.

3. Create the `restapi-ems` destination to receive the events:

   ```
   event notification destination create -name restapi-ems -rest-api-url
   https://<webhook-application>
   ```

   In the above command, you must use the **HTTPS** scheme for the destination.

4. Create the notification that links the `important-events` filter with the new `restapi-ems` destination:

   ```
   event notification create -filter-name important-events -destinations restapi-
   ems
   ```

Configure a webhook destination to use HTTPS with mutual authentication

You can configure ONTAP to forward event notifications to a webhook application using HTTPS with mutual authentication. With this configuration there are two certificates. ONTAP uses the server certificate to confirm the identity of the webhook application and secure the network traffic. In addition, the application hosting the webhook uses the client certificate to confirm the identity of the ONTAP client.

Before you begin

You must do the following before configuring ONTAP:

- Generate a private key and certificate for the webhook application server
- Have the root certificate available to install in ONTAP
- Generate a private key and certificate for the ONTAP client

Steps

1. Perform the first two steps in the task Configure a webhook destination to use HTTPS to install the server certificate so that ONTAP can verify the identity of the server.
2. Install the appropriate root and intermediate certificates at the webhook application to validate the client certificate.
3. Install the client certificate in ONTAP:

   ```
   security certificate install -type client
   ```

   The command will ask for the private key and certificate.

4. Create the `restapi-ems` destination to receive the events:

   ```
   event notification destination create -name restapi-ems -rest-api-url
   https://<webhook-application> -certificate-authority <issuer of the client
   certificate> -certificate-serial <serial of the client certificate>
   ```

   In the above command, you must use the **HTTPS** scheme for destination.

5. Create the notification that links the `important-events` filter with the new `restapi-ems` destination:

   ```
   event notification create -filter-name important-events -destinations restapi-
   ems
   ```

Update deprecated EMS event mapping

Learn about ONTAP EMS event mapping models

Prior to ONTAP 9.0, EMS events could only be mapped to event destinations based on event name pattern matching. The ONTAP command sets (`event destination`, `event route`) that use this model continue to be available in the latest versions of ONTAP, but they have been deprecated starting with ONTAP 9.0.

Beginning with ONTAP 9.0, the best practice for ONTAP EMS event destination mapping is to use the more scalable event filter model in which pattern matching is done on multiple fields, using the `event filter`, `event notification`, and `event notification destination` command sets.

If your EMS mapping is configured using the deprecated commands, you should update your mapping to use the `event filter`, `event notification`, and `event notification destination` command sets. Learn more about `event` in the ONTAP command reference.

There are two types of event destinations:

1. **System-generated destinations**: There are five system-generated event destinations (created by default)
   - `allevents`
   - `asup`
   - `criticals`
   - `pager`
   - `traphost`

   Some of the system-generated destinations are for special purpose. For example, the asup destination routes callhome.* events to the AutoSupport module in ONTAP to generate AutoSupport messages.

2. **User-created destinations**: These are manually created using the `event destination create` command.

```
cluster-1::event*> destination show
                                                                  Hide
Name             Mail Dest.        SNMP Dest.         Syslog Dest.
Params
---------------- ----------------- ------------------ ------------------
------
allevents        -                 -                  -
false
asup             -                 -                  -
false
criticals        -                 -                  -
false
pager            -                 -                  -
false
traphost         -                 -                  -
false
5 entries were displayed.
+
cluster-1::event*> destination create -name test -mail test@xyz.com
This command is deprecated. Use the "event filter", "event notification
destination" and "event notification" commands, instead.
+
cluster-1::event*> destination show
+
Hide
Name             Mail Dest.        SNMP Dest.         Syslog Dest.
Params
---------------- ----------------- ------------------ ------------------
------
allevents        -                 -                  -
false
asup             -                 -                  -
false
criticals        -                 -                  -
false
pager            -                 -                  -
false
test             test@xyz.com      -                  -
false
traphost         -                 -                  -
false
6 entries were displayed.
```

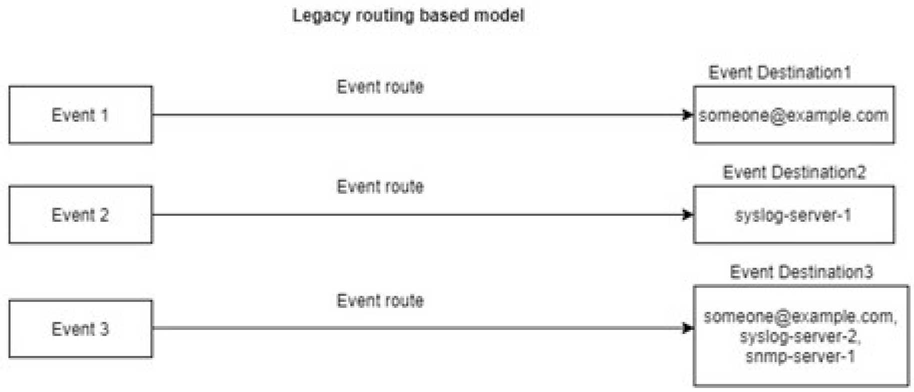
In the deprecated model, EMS events are individually mapped to a destination using the `event route add-destinations` command.

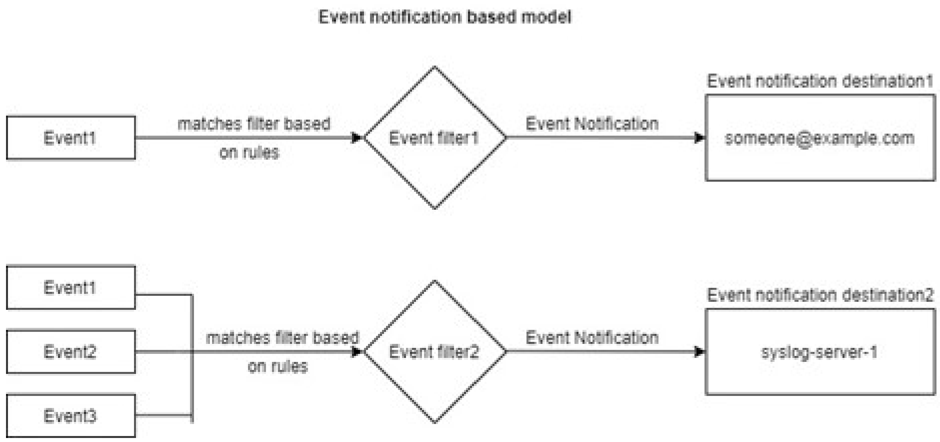
```
cluster-1::event*> route add-destinations -message-name raid.aggr.*
-destinations test
This command is deprecated. Use the "event filter", "event notification
destination" and "event notification" commands, instead.
4 entries were acted on.

cluster-1::event*> route show -message-name raid.aggr.*
                                                               Freq
Time
Message                          Severity       Destinations   Threshd
Threshd
-------------------------------- -------------- -------------- -------
-------
raid.aggr.autoGrow.abort         NOTICE         test           0       0
raid.aggr.autoGrow.success       NOTICE         test           0       0
raid.aggr.lock.conflict          INFORMATIONAL  test           0       0
raid.aggr.log.CP.count           DEBUG          test           0       0
4 entries were displayed.
```

The new, more scalable EMS event notifications mechanism is based on event filters and event notification destinations. Refer to the following KB article for detailed information on the new event notification mechanism:

- Overview of Event Management System for ONTAP 9





Update ONTAP EMS event mapping from deprecated commands

If your EMS event mapping is currently configured using the deprecated ONTAP command sets (`event destination`, `event route`), you should follow this procedure to update your mapping to use the `event filter`, `event notification`, and `event notification destination` command sets.

Steps

1. List all the event destinations in the system using the `event destination show` command.

```
cluster-1::event*> destination show

Hide
Name             Mail Dest.        SNMP Dest.         Syslog Dest.
Params
---------------- ----------------- ------------------ ------------------
------
allevents        -                 -                  -
false
asup             -                 -                  -
false
criticals        -                 -                  -
false
pager            -                 -                  -
false
test             test@xyz.com      -                  -
false
traphost         -                 -                  -
false
6 entries were displayed.
```

2. For each destination, list the events being mapped to it using the `event route show -destinations <destination name>` command.

```
cluster-1::event*> route show -destinations test
                                                               Freq
Time
Message                          Severity       Destinations   Threshd
Threshd
-------------------------------- -------------- -------------- -------
-------
raid.aggr.autoGrow.abort         NOTICE         test           0       0
raid.aggr.autoGrow.success       NOTICE         test           0       0
raid.aggr.lock.conflict          INFORMATIONAL  test           0       0
raid.aggr.log.CP.count           DEBUG          test           0       0
4 entries were displayed.
```

3. Create a corresponding `event filter` which includes all these subsets of events.
For example, if you want to include only the `raid.aggr.*` events, use a wildcard for the `message-name` parameter when creating the filter. You can also create filters for single events.

Learn more about `event filter` in the ONTAP command reference.

> You can create up to 50 event filters.

```
cluster-1::event*> filter create -filter-name test_events

cluster-1::event*> filter rule add -filter-name test_events -type
include -message-name raid.aggr.*

cluster-1::event*> filter show -filter-name test_events
Filter Name Rule     Rule      Message Name           SNMP Trap Type
Severity
            Position Type
----------- -------- --------- ---------------------- ---------------
--------
test_events
            1        include   raid.aggr.*            *               *
            2        exclude   *                      *               *
2 entries were displayed.
```

4. Create an `event notification destination` for each of the `event destination` endpoints (i.e., SMTP/SNMP/syslog)

```
cluster-1::event*> notification destination create -name dest1 -email
test@xyz.com

cluster-1::event*> notification destination show
Name            Type        Destination
--------------  ----------  ---------------------
dest1           email       test@xyz.com (via "localhost" from
"admin@localhost", configured in "event config")
snmp-traphost   snmp        - (from "system snmp traphost")
2 entries were displayed.
```

Learn more about `event notification destination` and `event destination` in the ONTAP command reference.

5. Create an event notification by mapping the event filter to the event notification destination.

```
cluster-1::event*> notification create -filter-name asup_events
-destinations dest1

cluster-1::event*> notification show
ID   Filter Name                     Destinations
---- ------------------------------  -----------------
1    default-trap-events             snmp-traphost
2    asup_events                     dest1
2 entries were displayed.
```

6. Repeat steps 1-5 for each `event destination` that has an `event route` mapping.

> Events routed to SNMP destinations should be mapped to the `snmp-traphost` event notification destination. The SNMP traphost destination uses the system configured SNMP traphost.

```
cluster-1::event*> system snmp traphost add 10.234.166.135

cluster-1::event*> system snmp traphost show
        scspr2410142014.gdl.englab.netapp.com
(scspr2410142014.gdl.englab.netapp.com) <10.234.166.135>    Community:
public

cluster-1::event*> notification destination show -name snmp-traphost

                Destination Name: snmp-traphost
             Type of Destination: snmp
                     Destination: 10.234.166.135 (from "system snmp
traphost")
 Server CA Certificates Present?: -
   Client Certificate Issuing CA: -
Client Certificate Serial Number: -
       Client Certificate Valid?: -
```

ONTAP command reference

For each major ONTAP release, the commonly available CLI commands (ONTAP manual pages, or man pages) are bundled into the ONTAP Command Reference. These command references explain how to use the CLI commands in each ONTAP release.

Man pages are also available at the ONTAP command line with the `man` command. Learn more about `man` in the ONTAP command reference.

Command references for limited support versions of ONTAP (PDF only)

- ONTAP 9.4

CLI comparison tool

You can learn about changes to the command-line interface (CLI) commands between ONTAP releases by using the CLI Comparison Tool on the NetApp Support Site.
