Manage workloads

Identify remaining performance capacity

Performance capacity, or headroom, measures how much work you can place on a node or an aggregate before performance of workloads on the resource begins to be affected by latency. Knowing the available performance capacity on the cluster helps you provision and balance workloads.

What you'll need
Advanced privilege level commands are required for this task.

About this task
You can use the following values for the -object option to collect and display headroom statistics:

- For CPUs, resource_headroom_cpu.
- For aggregates, resource_headroom_aggr.

You can also complete this task using System Manager and Active IQ Unified Manager.

Steps
1. Change to advanced privilege level:
   ```
   set  -privilege advanced
   ```

2. Start real-time headroom statistics collection:
   ```
   statistics start -object resource_headroom_cpu|aggr
   ```
   For complete command syntax, see the man page.

3. Display real-time headroom statistics information:
   ```
   statistics show -object resource_headroom_cpu|aggr
   ```
   For complete command syntax, see the man page.

4. Return to administrative privilege:
   ```
   set  -privilege admin
   ```

Example
The following example displays the average hourly headroom statistics for cluster nodes.

You can compute the available performance capacity for a node by subtracting the current_utilization counter from the optimal_point_utilization counter. In this example, the utilization capacity for CPU_sti2520-213 is -14% (72%-86%), which suggests that the CPU has been overutilized on average for the past hour.

You could have specified ewma_daily, ewma_weekly, or ewma_monthly to get the same information.
averaged over longer periods of time.

```bash
sti2520-2131454963690::*> statistics show -object resource_headroom_cpu
-raw -counter ewma_hourly
(statistics show)

Object: resource_headroom_cpu
Instance: CPU_sti2520-213
Start-time: 2/9/2016 16:06:27
End-time: 2/9/2016 16:06:27
Scope: sti2520-213

**Identify high-traffic clients or files**

You can use ONTAP Active Objects technology to identify clients or files that are responsible for a disproportionately large amount of cluster traffic. Once you have
identified these "top" clients or files, you can rebalance cluster workloads or take other steps to resolve the issue.

What you'll need
You must be a cluster administrator to perform this task.

Steps
1. View the top clients accessing the cluster:

   statistics top client show -node node_name -sort-key sort_column -interval seconds_between_updates -iterations iterations -max number_of_instances

For complete command syntax, see the man page.

The following command displays the top clients accessing cluster1:

   cluster1::> statistics top client show

   cluster1 : 3/23/2016 17:59:10

   *Total Client Vserver           Node Protocol    Ops

   ----------------- ------- -------------- ------- ------

   172.17.180.170     vs4 siderop1-vsim4      nfs    668
   172.17.180.169     vs3 siderop1-vsim3      nfs    337
   172.17.180.171     vs3 siderop1-vsim3      nfs    142
   172.17.180.170     vs3 siderop1-vsim3      nfs    137
   172.17.180.123     vs3 siderop1-vsim3      nfs    137
   172.17.180.171     vs4 siderop1-vsim4      nfs     95
   172.17.180.169     vs4 siderop1-vsim4      nfs     92
   172.17.180.123     vs4 siderop1-vsim4      nfs     92
   172.17.180.153     vs3 siderop1-vsim3      nfs     0

2. View the top files accessed on the cluster:

   statistics top file show -node node_name -sort-key sort_column -interval seconds_between_updates -iterations iterations -max number_of_instances

For complete command syntax, see the man page.

The following command displays the top files accessed on cluster1:
 Guarantee throughput with QoS

 Guarantee throughput with QoS overview

You can use storage quality of service (QoS) to guarantee that performance of critical workloads is not degraded by competing workloads. You can set a throughput ceiling on a competing workload to limit its impact on system resources, or set a throughput floor for a critical workload, ensuring that it meets minimum throughput targets, regardless of demand by competing workloads. You can even set a ceiling and floor for the same workload.

About throughput ceilings (QoS Max)

A throughput ceiling limits throughput for a workload to a maximum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput ceiling for workload 2 ensures that it does not "bully” workloads 1 and 3.

A policy group defines the throughput ceiling for one or more workloads. A workload represents the I/O operations for a storage object: a volume, file, qtree or LUN, or all the volumes, files, qtrees, or LUNs in an SVM. You can specify the ceiling when you create the policy group, or you can wait until after you monitor workloads to specify it.

Throughput to workloads might exceed the specified ceiling by up to 10%, especially if a workload experiences rapid changes in throughput. The ceiling might be exceeded by up to 50% to handle bursts. Bursts occur on single nodes when tokens accumulate up to 150%.
About throughput floors (QoS Min)

A throughput floor guarantees that throughput for a workload does not fall below a minimum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput floors for workload 1 and workload 3 ensure that they meet minimum throughput targets, regardless of demand by workload 2.

As the examples suggest, a throughput ceiling throttles throughput directly. A throughput floor throttles throughput indirectly, by giving priority to the workloads for which the floor has been set.

You can specify the floor when you create the policy group, or you can wait until after you monitor workloads to specify it.

Beginning in ONTAP 9.13.1, you can set throughput floors at the SVM scope with Adaptive policy group templates. In releases of ONTAP before 9.13.1, a policy group that defines a throughput floor cannot be applied to an SVM.

In releases before ONTAP 9.7, throughput floors are guaranteed when there is sufficient performance capacity available.

In ONTAP 9.7 and later, throughput floors can be guaranteed even when there is insufficient performance capacity available. This new floor behavior is called floors v2. To meet the guarantees, floors v2 can result in higher latency on workloads without a throughput floor or on work that exceeds the floor settings. Floors v2 applies to both QoS and adaptive QoS.

The option of enabling/disabling the new behavior of floors v2 is available in ONTAP 9.7P6 and later. A workload might fall below the specified floor during critical operations like volume move trigger-cutover. Even when sufficient capacity is available and critical operations are not taking place, throughput to a workload might fall below the specified floor by up to 5%. If floors are overprovisioned and there is no performance capacity, some workloads might fall below the specified floor.
About shared and non-shared QoS policy groups

Beginning with ONTAP 9.4, you can use a non-shared QoS policy group to specify that the defined throughput ceiling or floor applies to each member workload individually. Behavior of shared policy groups depends on the policy type:

- For throughput ceilings, the total throughput for the workloads assigned to the shared policy group cannot exceed the specified ceiling.
- For throughput floors, the shared policy group can be applied to a single workload only.

About adaptive QoS

Ordinarily, the value of the policy group you assign to a storage object is fixed. You need to change the value manually when the size of the storage object changes. An increase in the amount of space used on a volume, for example, usually requires a corresponding increase in the throughput ceiling specified for the volume.

Adaptive QoS automatically scales the policy group value to workload size, maintaining the ratio of IOPS to TBS|GBs as the size of the workload changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

You typically use adaptive QoS to adjust throughput ceilings, but you can also use it to manage throughput floors (when workload size increases). Workload size is expressed as either the allocated space for the storage object or the space used by the storage object.

Used space is available for throughput floors in ONTAP 9.5 and later. It is not supported for throughput floors in ONTAP 9.4 and earlier.

- An allocated space policy maintains the IOPS/TB|GB ratio according to the nominal size of the storage object. If the ratio is 100 IOPS/GB, a 150 GB volume will have a throughput ceiling of 15,000 IOPS for as long as the volume remains that size. If the volume is resized to 300 GB, adaptive QoS adjusts the throughput ceiling to 30,000 IOPS.
- A used space policy (the default) maintains the IOPS/TB|GB ratio according to the amount of actual data stored before storage efficiencies. If the ratio is 100 IOPS/GB, a 150 GB volume that has 100 GB of data stored would have a throughput ceiling of 10,000 IOPS. As the amount of used space changes, adaptive QoS adjusts the throughput ceiling according to the ratio.

Beginning with ONTAP 9.5, you can specify an I/O block size for your application that enables a throughput limit to be expressed in both IOPS and MBps. The MBps limit is calculated from the block size multiplied by the
IOPS limit. For example, an I/O block size of 32K for an IOPS limit of 6144IOPS/TB yields an MBps limit of 192MBps.

You can expect the following behavior for both throughput ceilings and floors:

- When a workload is assigned to an adaptive QoS policy group, the ceiling or floor is updated immediately.
- When a workload in an adaptive QoS policy group is resized, the ceiling or floor is updated in approximately five minutes.

Throughput must increase by at least 10 IOPS before updates take place.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

Beginning with ONTAP 9.6, throughput floors are supported on ONTAP Select premium with SSD.

Adaptive policy group template

Beginning in ONTAP 9.13.1, you can set an adaptive QoS template on an SVM. Adaptive policy group templates enable you to set throughput floors and ceilings for all volumes in an SVM.

Adaptive policy group templates can only be set after the SVM has been created. Use the `vserver modify` command with the `-qos-adaptive-policy-group-template` parameter to set the policy.

When you set an an adaptive policy group template, volumes created or migrated after setting the policy automatically inherit the policy. Any volumes existing on the SVM are not impacted when you assign the policy template. If you disable the policy on the SVM, any volume subsequently migrated to or created on the SVM will not receive the policy. Disabling the adaptive policy group template does not impact volumes that inherited the policy template as they retain the policy template.

For more information, see Set an adaptive policy group template.

General support

The following table shows the differences in support for throughput ceilings, throughput floors, and adaptive QoS.

**Enable or disable throughput floors v2**

You can enable or disable throughput floors v2 on AFF. The default is enabled. With floors v2 enabled, throughput floors can be met when controllers are heavily used at the expense of higher latency on other workloads. Floors v2 applies to both QoS and Adaptive QoS.

**Steps**

1. Change to advanced privilege level:
   
   ```
   set -privilege advanced
   ```

2. Enter one of the following commands:

<table>
<thead>
<tr>
<th>If you want to…</th>
<th>Use this command:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable floors v2</td>
<td><code>qos settings throughput-floors-v2 -enable false</code></td>
</tr>
<tr>
<td>Enable floors v2</td>
<td><code>qos settings throughput-floors-v2 -enable true</code></td>
</tr>
</tbody>
</table>

To disable throughput floors v2 in an MetroCluster cluster, you must run the

```bash
cluster1::*> qos settings throughput-floors-v2 -enable false
```

**Storage QoS workflow**

If you already know the performance requirements for the workloads you want to manage with QoS, you can specify the throughput limit when you create the policy group. Otherwise, you can wait until after you monitor the workloads to specify the limit.
Set a throughput ceiling with QoS

You can use the max-throughput field for a policy group to define a throughput ceiling for storage object workloads (QoS Max). You can apply the policy group when you create or modify the storage object.

What you’ll need

• You must be a cluster administrator to create a policy group.
• You must be a cluster administrator to apply a policy group to an SVM.

About this task

• Beginning with ONTAP 9.4, you can use a non-shared QoS policy group to specify that the defined throughput ceiling applies to each member workload individually. Otherwise, the policy group is shared: the total throughput for the workloads assigned to the policy group cannot exceed the specified ceiling.

   Set -is-shared=false for the qos policy-group create command to specify a non-shared policy group.

• You can specify the throughput limit for the ceiling in IOPS, MB/s, or IOPS, MB/s. If you specify both IOPS and MB/s, whichever limit is reached first is enforced.

    If you set a ceiling and a floor for the same workload, you can specify the throughput limit for the ceiling in IOPS only.

• A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
• You cannot assign a storage object to a policy group if its containing object or its child objects belong to the policy group.
• It is a QoS best practice to apply a policy group to the same type of storage objects.

Steps

1. Create a policy group:

   qos policy-group create -policy-group policy_group -vserver SVM -max-throughput number_of_iops|Mb/S|iops,Mb/S -is-shared true|false

   For complete command syntax, see the man page. You can use the qos policy-group modify command to adjust throughput ceilings.

   The following command creates the shared policy group pg-vs1 with a maximum throughput of 5,000 IOPS:

   cluster1::> qos policy-group create -policy-group pg-vs1 -vserver vs1 -max-throughput 5000iops -is-shared true

   The following command creates the non-shared policy group pg-vs3 with a maximum throughput of 100 IOPS and 400 Kb/S:
The following command creates the non-shared policy group \texttt{pg-vs4} without a throughput limit:

\begin{verbatim}
cluster1::> qos policy-group create -policy-group pg-vs4 -vserver vs4
          -is-shared false
\end{verbatim}

2. Apply a policy group to an SVM, file, volume, or LUN:

\begin{verbatim}
storage_object create -vserver SVM -qos-policy-group policy_group
\end{verbatim}

For complete command syntax, see the man pages. You can use the \texttt{storage_object modify} command to apply a different policy group to the storage object.

The following command applies policy group \texttt{pg-vs1} to SVM \texttt{vs1}:

\begin{verbatim}
cluster1::> vserver create -vserver vs1 -qos-policy-group pg-vs1
\end{verbatim}

The following commands apply policy group \texttt{pg-app} to the volumes \texttt{app1} and \texttt{app2}:

\begin{verbatim}
cluster1::> volume create -vserver vs2 -volume app1 -aggregate aggr1
          -qos-policy-group pg-app

cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1
          -qos-policy-group pg-app
\end{verbatim}

3. Monitor policy group performance:

\begin{verbatim}
qos statistics performance show
\end{verbatim}

For complete command syntax, see the man page.

\begin{itemize}
  \item [\textbullet] Monitor performance from the cluster. Do not use a tool on the host to monitor performance.
\end{itemize}

The following command shows policy group performance:
4. Monitor workload performance:

```
qos statistics workload performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows workload performance:

```
cluster1::> qos statistics workload performance show
```

<table>
<thead>
<tr>
<th>Workload</th>
<th>ID</th>

</tbody>
</table>

You can use the `qos statistics workload latency show` command to view detailed latency statistics for QoS workloads.

## Set a throughput floor with QoS

You can use the `min-throughput` field for a policy group to define a throughput floor for storage object workloads (QoS Min). You can apply the policy group when you create or modify the storage object. Beginning with ONTAP 9.8, you can specify the throughput floor in IOPS or MBps, or IOPS and MBps.

### Before you begin
- You must be running ONTAP 9.2 or later. Throughput floors are available beginning with ONTAP 9.2.
- You must be a cluster administrator to create a policy group.
- Beginning in ONTAP 9.13.1, you can enforce throughput floors at the SVM level using an adaptive policy group template. You cannot set an adaptive policy group template on an SVM with a QoS policy group.

### About this task
Beginning with ONTAP 9.4, you can use a non-shared QoS policy group to specify that the defined throughput floor be applied to each member workload individually. This is the only condition in which a policy group for a throughput floor can be applied to multiple workloads.

Set `-is-shared=false` for the `qos policy-group create` command to specify a non-shared policy group.

- Throughput to a workload might fall below the specified floor if there is insufficient performance capacity (headroom) on the node or aggregate.
- A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
- It is a QoS best practice to apply a policy group to the same type of storage objects.
- A policy group that defines a throughput floor cannot be applied to an SVM.

**Steps**

1. Check for adequate performance capacity on the node or aggregate, as described in Identifying remaining performance capacity.

2. Create a policy group:

   ```bash
   qos policy-group create -policy group policy_group -vserver SVM -min-throughput qos_target -is-shared true|false
   ```

   For complete command syntax, see the man page for your ONTAP release. You can use the `qos policy-group modify` command to adjust throughput floors.

   The following command creates the shared policy group `pg-vs2` with a minimum throughput of 1,000 IOPS:

   ```bash
   cluster1::> qos policy-group create -policy group pg-vs2 -vserver vs2 -min-throughput 1000iops -is-shared true
   ```

   The following command creates the non-shared policy group `pg-vs4` without a throughput limit:

   ```bash
   cluster1::> qos policy-group create -policy group pg-vs4 -vserver vs4 -is-shared false
   ```

3. Apply a policy group to a volume or LUN:

   ```bash
   storage_object create -vserver SVM -qos-policy-group policy_group
   ```

   For complete command syntax, see the man pages. You can use the `storage_object modify` command to apply a different policy group to the storage object.

   The following command applies policy group `pg-app2` to the volume `app2`:
cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1
           -qos-policy-group pg-app2

4. Monitor policy group performance:

qos statistics performance show

For complete command syntax, see the man page.

- Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows policy group performance:

<table>
<thead>
<tr>
<th>Policy Group</th>
<th>IOPS</th>
<th>Throughput</th>
<th>Latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>-total-</td>
<td>12316</td>
<td>47.76MB/s</td>
<td>1264.00us</td>
</tr>
<tr>
<td>pg_app2</td>
<td>7216</td>
<td>28.19MB/s</td>
<td>420.00us</td>
</tr>
<tr>
<td>_System-Best-Effort</td>
<td>62</td>
<td>13.36KB/s</td>
<td>4.13ms</td>
</tr>
<tr>
<td>_System-Background</td>
<td>30</td>
<td>0KB/s</td>
<td>0ms</td>
</tr>
</tbody>
</table>

5. Monitor workload performance:

qos statistics workload performance show

For complete command syntax, see the man page.

- Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows workload performance:

<table>
<thead>
<tr>
<th>Workload</th>
<th>ID</th>
<th>IOPS</th>
<th>Throughput</th>
<th>Latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>-total-</td>
<td>-</td>
<td>12320</td>
<td>47.84MB/s</td>
<td>1215.00us</td>
</tr>
<tr>
<td>app2-wid7967</td>
<td>7967</td>
<td>7219</td>
<td>28.20MB/s</td>
<td>319.00us</td>
</tr>
<tr>
<td>vs1-wid12279</td>
<td>12279</td>
<td>5026</td>
<td>19.63MB/s</td>
<td>2.52ms</td>
</tr>
<tr>
<td>_USERSPACE_APPS</td>
<td>14</td>
<td>55</td>
<td>10.92KB/s</td>
<td>236.00us</td>
</tr>
<tr>
<td>_Scan_Background..</td>
<td>5688</td>
<td>20</td>
<td>0KB/s</td>
<td>0ms</td>
</tr>
</tbody>
</table>

You can use the qos statistics workload latency show command to view detailed latency statistics for QoS workloads.
Use adaptive QoS policy groups

You can use an *adaptive QoS* policy group to automatically scale a throughput ceiling or floor to volume size, maintaining the ratio of IOPS to TBs|GBs as the size of the volume changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

**Before you begin**

- You must be running ONTAP 9.3 or later. Adaptive QoS policy groups are available beginning with ONTAP 9.3.
- You must be a cluster administrator to create a policy group.

**About this task**

A storage object can be a member of an adaptive policy group or a non-adaptive policy group, but not both. The SVM of the storage object and the policy must be the same. The storage object must be online.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

The ratio of throughput limits to storage object size is determined by the interaction of the following fields:

- **expected-iops** is the minimum expected IOPS per allocated TB|GB. 

  expected-iops is guaranteed on AFF platforms only. expected-iops is guaranteed for FabricPool only if the tiering policy is set to "none" and no blocks are in the cloud. expected-iops is guaranteed for volumes that are not in a SnapMirror Synchronous relationship.

- **peak-iops** is the maximum possible IOPS per allocated or used TB|GB.

- **expected-iops-allocation** specifies whether allocated space (the default) or used space is used for expected-iops.

  expected-iops-allocation is available in ONTAP 9.5 and later. It is not supported in ONTAP 9.4 and earlier.

- **peak-iops-allocation** specifies whether allocated space or used space (the default) is used for peak-iops.

- **absolute-min-iops** is the absolute minimum number of IOPS. You can use this field with very small storage objects. It overrides both peak-iops and/or expected-iops when absolute-min-iops is greater than the calculated expected-iops.

  For example, if you set expected-iops to 1,000 IOPS/TB, and the volume size is less than 1 GB, the calculated expected-iops will be a fractional IOP. The calculated peak-iops will be an even smaller fraction. You can avoid this by setting absolute-min-iops to a realistic value.

- **block-size** specifies the application I/O block size. The default is 32K. Valid values are 8K, 16K, 32K, 64K, ANY. ANY means that the block size is not enforced.

Three default adaptive QoS policy groups are available, as shown in the following table. You can apply these policy groups directly to a volume.
### Default Policy Group

<table>
<thead>
<tr>
<th>Default policy group</th>
<th>Expected IOPS/TB</th>
<th>Peak IOPS/TB</th>
<th>Absolute Min IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>extreme</td>
<td>6,144</td>
<td>12,288</td>
<td>1000</td>
</tr>
<tr>
<td>performance</td>
<td>2,048</td>
<td>4,096</td>
<td>500</td>
</tr>
<tr>
<td>value</td>
<td>128</td>
<td>512</td>
<td>75</td>
</tr>
</tbody>
</table>

You cannot assign a storage object to a policy group if its containing object or its child objects belong to a policy group. The following table lists the restrictions.

<table>
<thead>
<tr>
<th>If you assign the…</th>
<th>Then you cannot assign…</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVM to a policy group</td>
<td>Any storage objects contained by the SVM to a policy group</td>
</tr>
<tr>
<td>Volume to a policy group</td>
<td>The volume’s containing SVM or any child LUNs to a policy group</td>
</tr>
<tr>
<td>LUN to a policy group</td>
<td>The LUN’s containing volume or SVM to a policy group</td>
</tr>
<tr>
<td>File to a policy group</td>
<td>The file’s containing volume or SVM to a policy group</td>
</tr>
</tbody>
</table>

### Steps

1. Create an adaptive QoS policy group:

   ```bash
   qos adaptive-policy-group create -policy group policy_group -vserver SVM
   ```

   For complete command syntax, see the man page.

   - `expected-iops-allocation` and `block-size` is available in ONTAP 9.5 and later. These options are not supported in ONTAP 9.4 and earlier.

   The following command creates adaptive QoS policy group adpg-app1 with `-expected-iops` set to 300 IOPS/TB, `-peak-iops` set to 1,000 IOPS/TB, `-peak-iops-allocation` set to `used-space`, and `-absolute-min-iops` set to 50 IOPS:

   ```bash
   cluster1:/> qos adaptive-policy-group create -policy group adpg-app1
   -vserver vs2 -expected-iops 300iops/tb -peak-iops 1000iops/TB -peak-iops -allocation used-space -absolute-min-iops 50iops
   ```

2. Apply an adaptive QoS policy group to a volume:
volume create -vserver SVM -volume volume -aggregate aggregate -size number_of TB|GB -qos-adaptive-policy-group policy_group

For complete command syntax, see the man pages.

The following command applies adaptive QoS policy group adpg-app1 to volume app1:

```
cluster1::> volume create -vserver vs1 -volume app1 -aggregate aggr1
          -size 2TB -qos-adaptive-policy-group adpg-app1
```

The following commands apply the default adaptive QoS policy group extreme to the new volume app4 and to the existing volume app5. The throughput ceiling defined for the policy group applies to volumes app4 and app5 individually:

```
cluster1::> volume create -vserver vs4 -volume app4 -aggregate aggr4
          -size 2TB -qos-adaptive-policy-group extreme
```

```
cluster1::> volume modify -vserver vs5 -volume app5 -qos-adaptive-policy
          -group extreme
```

Set an adaptive policy group template

Beginning in ONTAP 9.13.1, you can enforce throughput floors and ceilings at the SVM level using an adaptive policy group template.

About this task

- The adaptive policy group template is a default policy apg1. The policy can be modified at any time. It can only be set with the CLI or ONTAP REST API and can only be applied to existing SVMs.
- The adaptive policy group template only impacts volumes created on or migrated to the SVM after you set the policy. Existing volumes on the SVM retain their existing status.
- If you disable the adaptive policy group template, volumes on the SVM retain their existing policies. Only volumes subsequently created on or migrated to the SVM will be impacted by the disablement.
- You cannot set an adaptive policy group template on an SVM with a QoS policy group.
- Adaptive policy group templates are designed for AFF platforms. An adaptive policy group template can be set on other platforms, but the policy may not enforce a minimum throughput. Similarly, you can add an adaptive policy group template to an SVM in a FabricPool aggregate or in an aggregate that does not support a minimum throughput, however the throughput floor will not be enforced.
- If the SVM is in a MetroCluster configuration or an SnapMirror relationship, the adaptive policy group template will be enforced on the mirrored SVM.

Steps

1. Modify the SVM to apply the adaptive policy group template: vserver modify -qos-adaptive -policy-group-template apg1
2. Confirm the policy was set: `vserver show -fields qos-adaptive-policy-group`
