    - Define TSM tape and disk storage pools ..... 1
    - Define a domain policy and register a node ..... 4
    - Create and activate the domain policy ..... 5

# Complete the Archive Node setup

The Archive Node is not functional after you complete the installation process. Before the StorageGRID system can save objects to the TSM Archive Node, you must complete the installation and configuration of the TSM server and configure the Archive Node to communicate with the TSM server.

Refer to the following IBM documentation, as necessary, as you prepare your TSM server for integration with the Archive Node in a StorageGRID system:

- [IBM Tape Device Drivers Installation and User's Guide](#)
- [IBM Tape Device Drivers Programming Reference](#)

## Install a new TSM server

You can integrate the Archive Node with either a new or an existing TSM server. If you are installing a new TSM server, follow the instructions in your TSM documentation to complete the installation.

An Archive Node can't be co-hosted with a TSM server.

## Configure the TSM server

This section includes sample instructions for preparing a TSM server following TSM best practices.

The following instructions guide you through the process of:

- Defining a disk storage pool, and a tape storage pool (if required) on the TSM server
- Defining a domain policy that uses the TSM management class for the data saved from the Archive Node, and registering a node to use this domain policy

These instructions are provided for your guidance only; they aren't intended to replace TSM documentation, or to provide complete and comprehensive instructions suitable for all configurations. Deployment specific instructions should be provided by a TSM administrator who is familiar both with your detailed requirements, and with the complete set of TSM Server documentation.

### Define TSM tape and disk storage pools

The Archive Node writes to a disk storage pool. To archive content to tape, you must configure the disk storage pool to move content to a tape storage pool.

#### About this task

For a TSM server, you must define a tape storage pool and a disk storage pool within Tivoli Storage Manager. After the disk pool is defined, create a disk volume and assign it to the disk pool. A tape pool is not required if your TSM server uses disk-only storage.

You must complete several steps on your TSM server before you can create a tape storage pool. (Create a

tape library and at least one drive in the tape library. Define a path from the server to the library and from the server to the drives, and then define a device class for the drives.) The details of these steps can vary depending upon the hardware configuration and storage requirements of the site. For more information, see the TSM documentation.

The following set of instructions illustrates the process. You should be aware that the requirements for your site could be different depending on the requirements of your deployment. For configuration details and for instructions, see the TSM documentation.

You must log in to the server with administrative privileges and use the `dsmadm` tool to execute the following commands.

## Steps

### 1. Create a tape library.

```
define library tapelibrary libtype=scsi
```

Where *tapelibrary* is an arbitrary name chosen for the tape library, and the value of *libtype* can vary depending upon the type of tape library.

### 2. Define a path from the server to the tape library.

```
define path servername tapelibrary srctype=server desttype=library device=lib-  
devicename
```

- *servername* is the name of the TSM server
- *tapelibrary* is the tape library name you defined
- *lib-devicename* is the device name for the tape library

### 3. Define a drive for the library.

```
define drive tapelibrary drivename
```

- *drivename* is the name you want to specify for the drive
- *tapelibrary* is the tape library name you defined

You might want to configure an additional drive or drives, depending upon your hardware configuration. (For example, if the TSM server is connected to a Fibre Channel switch that has two inputs from a tape library, you might want to define a drive for each input.)

### 4. Define a path from the server to the drive you defined.

```
define path servername drivename srctype=server desttype=drive  
library=tapelibrary device=drive-dname
```

- *drive-dname* is the device name for the drive
- *tapelibrary* is the tape library name you defined

Repeat for each drive that you have defined for the tape library, using a separate *drivename* and *drive-dname* for each drive.

5. Define a device class for the drives.

```
define devclass DeviceClassName devtype=lto library=tapelibrary
format=tapetype
```

- *DeviceClassName* is the name of the device class
- *lto* is the type of drive connected to the server
- *tapelibrary* is the tape library name you defined
- *tapetype* is the tape type; for example, ultrium3

6. Add tape volumes to the inventory for the library.

```
checkin libvolume tapelibrary
```

*tapelibrary* is the tape library name you defined.

7. Create the primary tape storage pool.

```
define stgpool SGWSTapePool DeviceClassName description=description
collocate=filespace maxscratch=XX
```

- *SGWSTapePool* is the name of the Archive Node's tape storage pool. You can select any name for the tape storage pool (as long as the name uses the syntax conventions expected by the TSM server).
- *DeviceClassName* is the name of the device class name for the tape library.
- *description* is a description of the storage pool that can be displayed on the TSM server using the query stgpool command. For example: "Tape storage pool for the Archive Node."
- *collocate=filespace* specifies that the TSM server should write objects from the same file space into a single tape.
- *XX* is one of the following:
  - The number of empty tapes in the tape library (in the case that the Archive Node is the only application using the library).
  - The number of tapes allocated for use by the StorageGRID system (in instances where the tape library is shared).

8. On a TSM server, create a disk storage pool. At the TSM server's administrative console, enter

```
define stgpool SGWSDiskPool disk description=description
maxsize=maximum_file_size nextstgpool=SGWSTapePool highmig=percent_high
lowmig=percent_low
```

- *SGWSDiskPool* is the name of the Archive Node's disk pool. You can select any name for the disk storage pool (as long as the name uses the syntax conventions expected by the TSM).
- *description* is a description of the storage pool that can be displayed on the TSM server using the query stgpool command. For example, "Disk storage pool for the Archive Node."
- *maximum\_file\_size* forces objects larger than this size to be written directly to tape, rather than being cached in the disk pool. It is recommended to set *maximum\_file\_size* to 10 GB.
- *nextstgpool=SGWSTapePool* refers the disk storage pool to the tape storage pool defined for the Archive Node.

- *percent\_high* sets the value at which the disk pool begins to migrate its contents to the tape pool. It is recommended to set *percent\_high* to 0 so that data migration begins immediately
- *percent\_low* sets the value at which migration to the tape pool stops. It is recommended to set *percent\_low* to 0 to clear out the disk pool.

9. On a TSM server, create a disk volume (or volumes) and assign it to the disk pool.

```
define volume SGWSDiskPool volume_name formatsize=size
```

- *SGWSDiskPool* is the disk pool name.
- *volume\_name* is the full path to the location of the volume (for example, */var/local/arc/stage6.dsm*) on the TSM server where it writes the contents of the disk pool in preparation for transfer to tape.
- *size* is the size, in MB, of the disk volume.

For example, to create a single disk volume such that the contents of a disk pool fill a single tape, set the value of *size* to 200000 when the tape volume has a capacity of 200 GB.

However, it might be desirable to create multiple disk volumes of a smaller size, as the TSM server can write to each volume in the disk pool. For example, if the tape size is 250 GB, create 25 disk volumes with a size of 10 GB (10000) each.

The TSM server preallocates space in the directory for the disk volume. This can take some time to complete (more than three hours for a 200 GB disk volume).

## Define a domain policy and register a node

You need to define a domain policy that uses the TSM management class for the data saved from the Archive Node, and then register a node to use this domain policy.

Archive Node processes can leak memory if the client password for the Archive Node in Tivoli Storage Manager (TSM) expires. Ensure that the TSM server is configured so the client username/password for the Archive Node never expires.

When registering a node on the TSM server for the use of the Archive Node (or updating an existing node), you must specify the number of mount points that the node can use for write operations by specifying the **MAXNUMMP** parameter to the **REGISTER NODE** command. The number of mount points is typically equivalent to the number of tape drive heads allocated to the Archive Node. The number specified for **MAXNUMMP** on the TSM server must be at least as large as the value set for the **ARC > Target > Configuration > Main > Maximum Store Sessions** for the Archive Node, which is set to a value of 0 or 1, as concurrent store sessions aren't supported by the Archive Node.

The value of **MAXSESSIONS** set for the TSM server controls the maximum number of sessions that can be opened to the TSM server by all client applications. The value of **MAXSESSIONS** specified on the TSM must be at least as large as the value specified for **ARC > Target > Configuration > Main > Number of Sessions** in the Grid Manager for the Archive Node. The Archive Node concurrently creates at most one session per mount point plus a small number (< 5) of additional sessions.

The TSM node assigned to the Archive Node uses a custom domain policy *tsm-domain*. The *tsm-domain* domain policy is a modified version of the “standard” domain policy, configured to write to tape and with the archive destination set to be the StorageGRID system's storage pool (*SGWSDiskPool*).

You must log in to the TSM server with administrative privileges and use the `dsmadm` tool to create and activate the domain policy.

## Create and activate the domain policy

You must create a domain policy and then activate it to configure the TSM server to save data sent from the Archive Node.

### Steps

1. Create a domain policy.

```
copy domain standard tsm-domain
```

2. If you aren't using an existing management class, enter one of the following:

```
define policyset tsm-domain standard
```

```
define mgmtclass tsm-domain standard default
```

*default* is the default management class for the deployment.

3. Create a copygroup to the appropriate storage pool. Enter (on one line):

```
define copygroup tsm-domain standard default type=archive  
destination=SGWSDiskPool retinit=event retmin=0 retver=0
```

*default* is the default Management Class for the Archive Node. The values of `retinit`, `retmin`, and `retver` have been chosen to reflect the retention behavior currently used by the Archive Node

Don't set `retinit` to `retinit=create`. Setting `retinit=create` blocks the Archive Node from deleting content, because retention events are used to remove content from the TSM server.

4. Assign the management class to be the default.

```
assign defmgmtclass tsm-domain standard default
```

5. Set the new policy set as active.

```
activate policyset tsm-domain standard
```

Ignore the "no backup copy group" warning that appears when you enter the activate command.

6. Register a node to use the new policy set on the TSM server. On the TSM server, enter (on one line):

```
register node arc-user arc-password passexp=0 domain=tsm-domain  
MAXNUMMP=number-of-sessions
```

`arc-user` and `arc-password` are same client node name and password as you define on the Archive Node, and the value of `MAXNUMMP` is set to the number of tape drives reserved for Archive Node store sessions.

By default, registering a node creates an administrative user ID with client owner authority, with the password defined for the node.
